The group gathered about the picture to admire. It showed a rather nice looking boy, with an outdoor flavour, and eyes that questioned.... The face was too young to have character.

"He's had on long trousers for six years!" said Annette. There was a hushed silence. "Isn't he _divine_!" gurgled one young person at length. Cecilia had only looked. The shadowy dream man vanished. The picture boy took his place.

This day Cecilia walked alone as usual. Mrs. De Pui was an advocate of trust as a developer of "womanly instinct," so on a stipulated number of streets, the girls were allowed to walk unchaperoned. They went in little groups, all except Cecilia. She was her own small group.

To-day she walked alone, at least it seemed so, but by her Cecilia felt K. Stuyvesant Twombly. "I admire art," he was saying. His voice, curiously enough, was Mrs. De Pui's.

"So do I," agreed Cecilia. "Beauty develops us, the best of us, and brings a shining light into the soul." Cecilia stopped. Then because she was very truthful she went on: "That is not original. The man who lectures us on Art said it. He has whiskers and false teeth, I believe, for they click when he says, 'Renaissance.'" ... "Oh, Heavens!" thought Cecilia, "I will never be a lady. That would not be the way to talk to the ideal man. About teeth!--false ones!"

Then the cat had appeared. Rather Cecilia had nearly walked on it. It was a limp little grey and white heap, its fur half wet from the gutter, and eyes half closed.

"Poor pussy," said Cecilia. "You look like I feel when I'm with them what have social advantages. Poor pussy!" She was very tender toward it. She leaned above it, then picked it up. "I will bribe Annie, with dresses, to feed it," she thought. The cat began to be violently ill. Cecilia put it down.

"I say!" came in a rather husky voice, "Pussy needs some Mothersill's, doesn't she?"

Cecilia didn't understand the allusion, but she looked up smiling. The voice had been attractively hearty. After she looked up, she gasped.

"What are you going to do with it?" went on the young man.

"I thought I'd take it to my school and get the hired girl,--I mean maid,--to feed it."

"No," objected K. Stuyvesant; "it's poisoned. We'll take it to a drug store and get them to kill it."

"Oh, _no_!" said Cecilia.

"See here," said the boy, "the cat will die. I've had dogs of mine poisoned. It's the most merciful thing to have it killed. It'll only suffer and drag its life out if you take it home."

"I see," said Cecilia. "I suppose you know. It's just as you say."

"Good kid," he commented. His comment called forth an agony and elation. Cecilia wished for the longer dresses with which she'd come to school. The boy picked up the cat gently and wrapped his handkerchief about it.

"Come on," he said. "Drug store around the corner."

Cecilia followed. She could not keep up to him. Half the time she ran. The whole affair was humiliating.

"Thank the Lord no one saw me!" said the boy when they got inside the drug store. He looked at Cecilia. They both laughed.

"Sit down," he said. "I'm going to buy you a soda." Cecilia sat down. "Choclut," she ordered. He sat down opposite her, and put his arms on the sticky little table. He thought he looked on the prettiest child he'd ever seen.... She seemed entirely and only a child.

"What's your name?" he asked.

"Cecilia Evangeline Agnes Madden," she answered.

"Well, Cecilia Evangeline," he said, "don't try to eat the bottom of the glass; I'm wealthy to-day. I'm going to buy you another soda!"

"Oh," answered Cecilia, "I really oughtn't." At a motion the clerk bent above her. "C-could I have a sundae?" asked Cecilia. The boy laughed and nodded.

"Peach," said Cecilia, "with a good deal of whipped cream on top, if you please!" She smiled frankly on K. Stuyvesant. "I'm having a _fine_ time!" she said. Her sentimental dreams of him had vanished. He didn't talk a bit like the phantom, but he was _nicer_!

"What's your name, please?" she asked. She knew, but little Cecilia at fourteen was a woman.

"Keefer Stuyvesant Twombly," he answered. "Rotten name. Imagine being hailed as 'Keefer'! It sounds like some one's butler. It isn't a nice name, is it, Evangeline Cecilia?"

"No," said Cecilia. "But then, you are nice. Names and things are just trimmings. _You_ are nice," she repeated.

"So are you," returned the boy, "and I'll _bet_ you're Irish!"

"_How_ did you know?" asked Cecilia, wide-eyed. "How did you know?"

"And there she sat," said the green-eyed, "laughing with him in the most brazen way, and he bought her two sodas!"

"How vulgar," said Annette. "Was he good looking?"

"Ravishing, my dear. Alice thought that he looked like your cousin."

"That, of course, is impossible," said Annette coldly. "He _does_ happen to be here. He and his mother are at the Touraine. But as for his looking at any one like that Madden girl--! How she got in here, I can't imagine. I think that it is an imposition to be asked to meet her."

Annette surveyed her hair, and picked up a mirror. "Did you tell Mrs. De Pui?" she asked.

"Yes," answered the green-eyed; "I thought that it was my _duty_. It hurt me to do it, but I thought I _ought_ to. We watched them for the longest time. We pretended to be looking at a window full of hot water bottles."

Alice came in. She picked up the photograph of K. Stuyvesant Twombly. She nodded at the green-eyed after she looked long.... Annette saw this in the glass and glared.

CHAPTER V

DISGRACE

The day had been terrible for Cecilia. She had learned from Mrs. De Pui that she had hopelessly offended.... What she had done, Mrs. De Pui said, was an act suitable for one of the maids. Mrs. De Pui was pained. She could not believe that one of her pupils, with the womanly inspiration of the school set before her, could have so offended. It was unthinkable!

Cecilia wriggled, and swallowed with difficulty.

"Cultivate repose," ordered Mrs. De Pui coldly. Cecilia stood so rigidly that she looked like a wooden Indian. One of the girls entered. She said, "Excuse me," and backed away, plainly much interested.

"What was the boy's name, Cecilia?" asked Mrs. De Pui. Cecilia swallowed so hard that she shook. "I don't know," she answered loudly.

Then what Mrs. De Pui said was very terrible. Cecilia crawled off at last, white and shaking. She groped for her door knob. Things before her were not very clear. What Mrs. De Pui had said was very terrible, but,--but the other, her first lie, uttered with that brazen assurance.... She went in and threw herself across the bed.... She didn't cry. The hurt was too big. So her dear father and the fact that she was born in poverty made her an outcast? If so, she would stay so. "Learn her to be a lady," the breeze that came in through an inch opened window whispered. Cecilia felt it, and set her chin.

And Mrs. De Pui hadn't believed her story. Hadn't believed her.... "One more try, Cecilia, although you are a great trial both to me and my pupils," echoed through her brain in Mrs. De Pui's cold tones. Cecilia sat upright on the bed. "My heart's right," she said aloud. "I believe it's better than Annette's. Don't that count for nothing? Ain't being kind being a lady?" She stared sullenly across the room. The white furniture glittered coldly. From between the flutter of scrim curtains she saw a painfully well arranged park. Even the trees were smugly superior.

"Gawd _was_ in that flat," she said, and again aloud. A sentence came to her mind. A sentence that is shopworn and has been on the top shelf for many years. "I guess Gawd is what I feel fer paw,--" she said, half musingly,--"Love. An' fer Johnny, even when he's bad, an' Father McGowan, dear, an' Norah. Just that." ... She looked out of the window and saw the painfully well regulated trees again. "Them trees ain't so bad," she stated; "at least they ain't when I remember that they love me at home." Her face changed, for she remembered some of Mrs. De Pui's well-aimed truths. Her father,--his difference. It should always be hers, too, she decided.

Her first touch of hate came. "Gawd, make me a lady quick!" she implored. Some one tapped on the door. Cecilia opened it. Annie was there, beaming. She held a long box with stems sticking out of one end of it. "Fer you, dearie," said Annie. Cecilia opened the box with trembling hands. The box held pink roses, very, very pink roses.... On the top lay a card. On it was written in a loose, boy-hand: "For little 'A-good-deal-of-whipped-cream-on-top.'" Cecilia stared at the card, breathless.

"Annie," she-said at last, "ain't they lovely?"

"Aren't, dearie," corrected Annie, and then added, "You bet they are! You bet!" Cecilia lifted them reverently. There were three dozens of them. Her years were such that numbers and prices still counted.

"Who shall I tell _her_ they're from?" asked Annie. "Yuh got her goat, yuh know."

"Father McGowan," answered Cecilia. Suddenly the guilt of the other lie, her shame over the act unthinkable, and her new realisation of the standing of those she loved, slid from her soul. She was wildly happy. She hugged Annie.

The white furniture didn't glitter coldly. It smiled. A crowded flat was far away. The trees in a smug park were beautiful.

"One new frock," read Father McGowan, "twenty-five dollars. Hat, fifteen. 'Madam Girard's skin food, and wrinkle remover,' two dollars and fifty cents. Flat-heeled shoes, seven dollars. Taxi, one dollar and fifty-two cents. Church offering, ten cents."

Father McGowan threw back his head, and laughed loudly. Jeremiah Madden looked on him, bewildered.

"It's her cash account, yuh know. Twenty-five dollars fer one dress," he mused, with a pleased smile. "_Ain't_ she learnin' quick? But the letter," he added, with a perplexed frown appearing, "it sounds _too_ happy. The happiness is a little _too_ thick. Smells like she put it on with a paint brush jest fer show."

"Hum----" grunted Father McGowan.

He opened a pink letter sheet. At the top of it a daisy was engraved. "I give her that paper," said Jeremiah proudly. "She _was_ tickled. She sez as how none of the girls in school had nothing like it."

"I believe it," replied Father McGowan. There were heavy lines in his face. Cecilia's heart-ache lay on his shoulders, he felt, for he had made the "Brick King."

"Darling Papa:" read Father McGowan, "I was so happy to hear from you. I read your letters over and over. I love you very much. I am learning that that is the biggest thing in the world, loving people, and having them love you. I miss you, but of course I am happy.

"The School is elegant very nice, and I get enough to eat. The view from the front windows is swell beautiful. It looks right out on the Park, all over fancy foliage and rich people walking around. I sometimes walk there, and one little girl, awfully cute, with bare legs and a nurse, likes me. Yesterday she threw a kiss to me. She looked like Johnny when he was little, and we lived in the flat. It made me want to cry.

"I am very happy. You do so much for me. I will be very happy when I can come home to you and Johnny, and we can have Father McGowan to supper dinner every Saturday night. I am sending some things that look like fruit knives, but which are butter spreaders, and are used to apply butter to bread, etc. (i.e., not to eat off of).

"I am very happy. I went to one party in an exclusive girl's room. It was kind of her to ask me. I love you so much, Papa. Please kiss Johnny for me, and Norah. Tell her to use the butter spreaders daily. (_All_ the time.)

"She need not cherish the blue glass butter dish any more.

"I do love you, dear Papa. Your,

"CECILIA."

"P.S.: I send my respectful regards to Father McGowan, and thanks for getting me into this exclusive School, which caters only to sophisticated people with money.

"C."

"Well?" asked Jeremiah, after Father McGowan had laid down a pink sheet of paper with an engraved daisy at the top. "Well?"

"Hum," grunted Father McGowan, "Hum!" He stared long at a brick which lay on the top shelf of a gilt cabinet. "I'm going up to Boston," he said at length. "I'll look in on our little Cecilia."

"Will yuh, now?" asked Jeremiah. "It's kept me awake nights, thinkin' that mebbe in spite of all the expense, she wasn't happy. I wanted to go up, but Johnny sez I wasn't suitable fer a girls' school, being as I remove my collar absent-minded like (having always did it)."

"You're suitable, all right," said Father McGowan, "but since I am going up, I might as well attend to it. Hard for you to leave business, too."

"Yes," admitted Jeremiah happily. He swelled and cast a loving eye toward the brick. Then he wilted. The proud pleasure was gone. "_She_ always wanted a bunnit with pink roses on," he said in a low voice, "an' I couldn't never buy her none, an' now----!"

Father McGowan laid a hand on Jeremiah's. "There, there, Jerry!" he said. "Think how happy you're making the children!"

A sallow boy came in. He cast a sneering look at a limp figure in a gilt chair. Then, without a word, he picked up a book and went out.

Jeremiah's eyes were like a child's--the eyes of a frightened child. "Sometimes," he said in a whisper, "I'm afraid he's _ashamed_ of me!"

"No!" exploded Father McGowan, "No!"

There is nothing like the scorn of the undetected guilty for those who are exposed. Cecilia was treated to fine scorn, supercilious looks, and, worst of all, a chill overlooking; for she had allowed a boy whom she'd never met to buy her a soda water and a pink sundae! And,--what made the offence doubly revolting?--was the fact that the boy was considered by the girls a man, and that those who had seen him termed him "_Ravishing_, my dear!" He,--but let us quote: "Simply _Rav_ishing, my dear, with dark eyes and hair. _Hon_estly, he looked as if he had a secret sorrow, or was on the stage, or was _fear_fully fast. Something wonderfully interesting about him, you know. Why he would _ever_ look at _her_, I can't see,----" etc.

Cecilia sat in the corner of the shabby-impressive room. She was reading "Sordello" because it was required by the English teacher. Cecilia wasn't a bit interested, and twice the book had slipped shut, and she hadn't known at all where she'd left off, which was annoying; she was afraid she might read one page twice, and she couldn't bear the idea of that. She wondered if this Browning person could have made a success at manufacturing bricks? She judged not. He didn't seem practical, but inwardly she was sure that he could have done anything better than write poetry. She really wondered quite a little bit about him, but after the laughter of the class on her question: "Is Mr. Browning an American or does he come from the Old Country?" she had ceased to voice her speculations.

She turned the pages fretfully. There were a great many more. She hoped that Mr. Browning was dead, so that he wouldn't write any more stuff that they would be required to read. Then she berated herself soundly for this unholy wish.

Annette Twombly and a girl with tawny hair and green eyes came in. When they saw Cecilia they raised their eyebrows.

"There seems to be _no_ privacy in this place!" said Annette. Cecilia turned a page.

"And what is worse, my dear," answered the green-eyed, "one is constantly called upon to meet persons socially inferior--the kind suitable to the kitchen and associating with the policeman."

Cecilia had turned another page, but she had not read it. The print was jumping dangerously from the quick pump of her heart. "I will not move," she thought. "I will not move, nor show them that I hear."

"Imagine allowing an unknown man to buy you sodas!" said Annette, who was looking out of the window. "Isn't it utterly _hope_less?"

There was a pained silence. The hopelessness of it had evidently eaten deeply into the systems of Annette and the green-eyed.

"Milk, an' sugar, if yuh have it," mimicked the green-eyed. She scored her point. Cecilia's book closed. She got up quickly and went toward the door. There she paused with her hand on the jamb. "I hope it pleases you to make me so unhappy," she said quietly, "for otherwise I don't know what you are accomplishing." Then she went upstairs to an always lonely room. She closed the door gently and lay across the bed, staring at the ceiling. She never cried any more. She reached beneath the pillow. Her cold and moist little hand closed about the letter of a brick king.

"I love you!" she whispered fiercely. "I shall make you proud of me, but Maw, I'm glad you died before the roses came! I'm glad! I'm glad! ... They have so _many_ thorns!"

The young ladies downstairs didn't giggle as usual. They avoided each other's eyes. At last Annette said, "Upstart! How dared she speak to me that way!" It was said in an effort to reinstate her superior right to exercise the rack. The green-eyed didn't answer. She looked out of the window. At last she said carelessly, "Going to dress." And Annette was not invited to her room.

The green-eyed stood still just inside her door. She thought of a fat father, and of his code of morals. The mother whom her eyes came from was very distant.

"It has been utterly devilish!" she said loudly. "Utterly. And I did it while I read 'The Mob,' and ranted over it." Then she threw a book across the room, which spelled emotional crisis for her temperament and, this time, reform. Her green eyes were full of healthily ashamed tears.

CHAPTER VI

A HINT OF PINK

Cecilia sat well forward in the parquet seats of an opera house in Boston. Her small hand was curled up in the fat palm of a fat priest. The people who saw this smiled indulgently, then looked again; for the little girl was so pretty, and so happy, and the man's face was unusual.

The curtain had not gone up. They were a good fifteen minutes early.

"You see, Father McGowan-dear," said Cecilia, "it was not just their fault, for I am so different. I am still, but less so.... Then one day they said more than usual while I was reading that Sordello poem. (It isn't interesting, is it?)" Father McGowan smiled and shook his head. "And I thought I just couldn't stand it. I was so miserable that I even thought of taking the veil!" Father McGowan laughed suddenly. Cecilia looked at him with questioning eyes. "Go on, dear," he said gently, "and excuse a bad-mannered old priest."

She squeezed his thumb and continued: "Well, it was that day I decided to go home. I decided I could not be a lady, I mean I could not acquire a _savoir faire_ (that means a natural swellness)," explained Cecilia. Father McGowan nodded. His eyes twinkled. "So," said Cecilia, "I took all my money, and put on my hat and sneaked out. Then I walked down the block and across the Park. I saw a baby in the Park, a little girl, and she makes me think of Johnny when he was little and I took care of him. Then I thought of maw, and how she wanted me learned, I mean taught, and I went back. I am not very brave, and I wanted to cry dreadfully. I got in the hall, and there was Mrs. De Pui. She looked awfully cold, and she said, 'May I ask where you have been, Cecilia?' and then, that green-eyed girl I hated broke right in and said, 'I had a slight headache, and I asked her to post a letter for me, Mrs. De Pui. I _hope_ you don't mind.' The green-eyed girl is very rich, and so Mrs. De Pui said so sweetly that she hadn't minded at all.

"She always says 'post' instead of 'mail,' Father McGowan-dear. She spent two weeks in London last summer, and she said that the English accent became unconscious, or at least that she used it unconsciously. And she does except when she gets excited or talks fast.

"Well, she followed me upstairs, the green-eyed one, her name is Marjory, and I said, 'I do thank you.' Then I felt mean about the way I'd felt toward her, and I added, 'I am very sorry that I have hated you so.' Then she kissed me, Father McGowan-dear. Really, she did, and she said she was _glad_ I'd hated her. That it helped. She went down the hall, and paused at the turn to say, 'It is a great deal to ask, but some day I hope you'll like me!' Oh,--the curtain's going up! Look at that yellow dress. Aren't her legs _beautiful_? Mine are _so_ skinny!"

There was a burst of music, and the chorus waved their arms with the regularity of the twist of aspen leaves, when rain is coming.

Cecilia gasped. Then she sat breathless, watching every motion on the stage. A fat priest sat looking down at her. Once he took off his glasses and polished them. Something was making them misty.

The curtain went down. Cecilia gasped again, then she told of the awful, humiliating sick-cat episode, and of her disgrace in accepting a "choclut soda," and a pink sundae with whipped cream on top. Father McGowan was very understanding. He did not think it was a sin. In fact he was quite violently sure it was not. He grew very red in the face.

"What is the matter with that woman?" he asked in an entirely new, and really horribly stern tone. Cecilia didn't answer. Her startled eyes recalled him. "By George!" he said. "I forgot the candy!" and he produced from a coat pocket the most beautiful box.

"_Oh_," said Cecilia, "oh!" She smiled up into Father McGowan's face, and then added, "I can put that ribbon in a chemise. Oh, dear Father McGowan!"

"What is a priest to do," asked Father McGowan, "when all his inclinations are to kiss a young lady's hand?"

"I am so happy!" said Cecilia. Father McGowan put his other hand on the small one that lay in his. Cecilia tightened her little fingers about his thumb.

Father McGowan pushed away his plate. The chops were underdone, the potatoes soggy.

"Here's yer coffee," said Mrs. Fry. She was a perfect person for the housekeeper of a priest, being so visited with warts and a lemon expression that questioning her morals was impossible. Father McGowan stirred the coffee, then took a sip. He sighed. "Well,", he thought, "at least it makes fasting easier!"

In the hall of the rectory were twelve people. They were all shabby, and a boy of eleven sniffed with a wonderful regularity. They were all waiting to see a fat priest. A girl with sullen eyes and once pretty face looked around with defiant assurance. Opposite her on the wall hung a carved wood crucifix. When her eyes met that, she shrank, and then she'd look away, and again be sullenly brazen.

A well-dressed man rang the bell. The warted housekeeper answered it.

"I should like to see Father McGowan," he said. "I will only need a few moments of his time," he added on seeing the people waiting.

"Set down," ordered Mrs. Fry. "You'll have to wait yer turn." The man smiled. He was faintly amused. "I hardly think so," he said; "I am Doctor Van Dorn. My time is rather valuable. I can hardly waste it in that way."

"It's his rule," said Mrs. Fry, nodding her head toward the rear of the hall. "All who waits is the same. Yuh waits yer turn, or yuh goes. _He_ don't care." She had fixed her eyes above the man's head with all her words. He looked on her, frowning deeply, then said with an unconcealed irritation showing in his voice: "Will you at least take him my card?"

Mrs. Fry nodded. She held out a palm that looked damp, then went down the hall, reading the card as she walked. "He needn't be so smart," she made mental comment. "_Here_ he ain't no better than none of the rest." She went toward the table at which Father McGowan sat and shoved the card toward him. "He wants to see yuh right off, _now_," she said.

Father McGowan picked up the card, read it, and then laid it aside. "Tell him the rules," he said shortly. He turned back to a page of pink letter paper, with a daisy engraved on its top. He glanced from it to the clock. He still had twenty minutes before work began.

"Dearest Father McGowan, dear:" was written on the pink sheet. It was crossed out and below it was written, "Respected Father:--(I meant the first, but I suppose this is properer.) I can't tell you how happy you made me by the play and everything. I have put the pink ribbon in a chemise where it looks decorative, and cheers me up, as I like pink ribbons in underwear, although white are better taste. I am much happier. I am not _always_ happy, but do not tell Papa, nor any one that I am not. I _am_ much happier than I was.

"I apologise for clinging to you and kissing your hand good-bye when you left, but I am not sorry. It was very hard to let you go. Pink roses seemed _all_ thorns just then."

Father McGowan stopped reading. He looked across the room with far eyes. They were surrounded by fat wrinkles, and made small by thick lenses, but they were rather beautiful.

"I wanted to do as you suggested and try another school," he read, "but I somehow feel that I must finish what I've started, and I would like to show these girls that my soul is not purple silk trimmed with green velvet, if you can understand that; they seem to judge everything by rhinestone hair-pins, which is not a real clue to character.

"When you go to dinner with Papa, see that Norah uses the butter spreaders, which are small knives shaped like fruit knives. I will be deeply grateful. They are used for buttering bread, and so on (not to eat from).

"We are studying art. Andrea Dalsartoe, who painted the Madona of the Chair, just now. Marjory is so kind to me. She is an Episcopal but nice in every other way. They say a prayer to themselves when they go into church, too. She says, 'Peanuts, popcorn, and chewing gum, amen,' which I do not think is _very_ devout. She says it is just the right length when said _slowly_.

"You did make me so happy by that play and the candy. I have never had a better time but once, after which I was disgraced and sorry. (I had not met him socially, you know, which made it improper to eat sundaes with him, even while on an errand of mercy to a sick and dying cat.)

"We hear an orchestra every Saturday, chaperoned by our English teacher, who has asthma horribly and splutters a great deal. The music is classical and improving. I do not enjoy it very much, but there is a man in the orchestra who has an Adam's apple that wiggles and he helps me. One can always find enjoyment when looking for it, can't one? He plays a horn, and blows the spit from it often. He seems to have a great deal of spit.

"I have not thanked you the way I wanted to for the play, and everything, not forgetting the taxi ride and the sundae afterward. I do love you, Father McGowan, dear. I believe if there were more priests who believed in God, _and_ pink boxes of candy, there would be more Christians.

"Most respectfully, and lovingly, "CECILIA."

The clock struck one. Father McGowan folded up a pink sheet, and put it, in its envelope, in his pocket.

He was smiling gently. He opened the door into the hall, and the people struggled tiredly to their feet.

"Pax Tibi!" he said with a hand above his head. A girl with sullen eyes sobbed aloud. A Doctor sneered.

Much later the Doctor was admitted to a rather bare room, made tolerable by the colours of the books which lined its walls. The priest sat behind a table. They exchanged the usual formalities, then Father McGowan said: "Well?" Doctor Van Dorn shifted uneasily. "It is difficult to explain," he said. "I don't know just how to put it, but I thought you, if any one, could help me."

"I shall do all in my power to help you, if I think you need help," answered Father McGowan. The Doctor picked up a paper knife. He toyed with it, then blurted out: "I feel sure that there must be some reason for it, and that he's merely doing it from some evil wish."

"Who? Doing what?" asked Father McGowan.

The Doctor looked silly and laughed uneasily. "I'm not very coherent," he said.

"Oh, well," said Father McGowan, "we're both doctors in a way. We both meet that enough to understand it. Now take your time and tell me your story in your own way." He pushed a box of cigars across the table. "Want to smoke?" he asked with the move. The Doctor nodded and lit a cigar.

"It concerns a man named Madden," he said, "who, I have found, is one of your people. I have no proof, at least of the tangible sort, but I believe he is doing all he can to ruin me.... He is succeeding fairly well, too."

"Well, well," said Father McGowan. "Now what's he doing?"

"It began," said the Doctor, "with my hospital, which you know is a private affair, and in which some of my fellow doctors, with me, do some experimental work. The most of my clientele consists of the rather more well-known people of this city, as you know."

Father McGowan nodded. The Doctor's voice was as usual, and he began to swell a bit, with the tale of his hospital and its clientele.

"I rarely take charity work," said the Doctor. "All New York is after me...." Suddenly his face changed. "Was after me," he corrected. He studied the end of his cigar. "I did take one small chap," he went on slowly, "a charity case. He interested me. The complications were most unusual; however, you would not understand about them, and they do not influence the tale. I took him in and gave him the best of care, even to giving him a hundred-dollar room and an especial nurse. (His case was most interesting.) Well, as you know, the action of the muscles and organs is changed by anesthesia. I--ah,--I did but the slightest experimental work, keeping him well-fed, you know, and in this hundred-dollar-a-week room. The best of care, as I explained. He,--ah,--himself submitted to this slight pain when I told him that after it he would run and play as other boys. He had a natural, childish desire to run and play. Quite natural, I suppose."

"I suppose so," said Father McGowan. His tone was dry. His expression was very different from that which he had worn while reading the pink letter sheet.

"Then one day when a slight,--very slight, I assure you,--operation was absolutely necessary to his getting well, he said he would not, could not endure it. He had been quite weakened by his being in bed, and so on, but he screamed wildly. What he said was most improper and very ungrateful. He turned against us suddenly, as is the way of some when diseased." The Doctor stopped. He had grown rather white. He was again in a hundred-dollar room, which had a slat door, and no way to keep the voice of a frenzied

charity patient from the rest of his aristocratic hospital. He heard the voice again: "Gawd, no, youse devils! ... Youse are killing me! Lemme die! Oh, Mister, don't strap me down! I can't stand it no more.... Don't--don't! Christ ... Christ ... Kill me, but don't----"

The Doctor moistened his lips, and came back to the bare room in St. Mary's Rectory. "He was most ungrateful," he said to Father McGowan, "and he bit my hand when I tried to silence him." Father McGowan was looking out of the window. The Doctor went on less surely. "A woman who scrubbed the floors heard this, and, as is the way with her class, got emotionally aroused. It seems she lived in a tenement, and had lived there when Jeremiah Madden had lived across the hall, before he made his money. She went to see him. He removed the lad from my care, and with his malicious help, lied viciously about me and my work, scattering statements broadcast, and giving their statements to the papers. My own profession do not largely back me up, being, I suppose, jealous, and of little spirit. I think they recognise my skill too well to love me. You read those articles?" he asked, turning to Father McGowan.

"That has nothing to do with your narrative," answered Father McGowan. "Please go on."

"Well," said the Doctor, his well-bred voice holding a hint of frost, "it,--that is, this malicious attack,--had prejudiced many. For the good of this Madden man's soul you should help him to be truthful, not to so belittle his nature by----"

"You're worried about his soul?" said Father McGowan. "Is _that_ why you came to me?" Father McGowan smiled. The Doctor shifted in his chair. There was the staccato tap of crutches on the bare floor of the hall. The knob of the door turned.

"Father," came in a small boy's voice from the doorway, "I brung yuh a toad. I want youse to bless it. It's dead. It was a cripple, too. I found it all mashed. You'll bless it? Me an' the fellers is going to bury it. _Ain't_ it cute?"

The Doctor had not turned.

"Come in, little Saint Sebastian," said Father McGowan. The little boy gave him a look that was pathetically adoring. His crutches tapped across the bare floor. Opposite the Doctor, he looked at him. Suddenly he screamed.

"Gawd! My Gawd! Oh, Father McGowan,--_don't_--let him have me!" He clung to Father McGowan's cassock as he sobbed out his broken prayer. "Don't, Mister, don't!" he ended weakly. Father McGowan picked him up. He looked at the Doctor.

"Go," he said.

Father McGowan again settled back of a bare table. A little boy sobbed in his arms. "Will you forgive me, little Saint Sebastian?" asked Father McGowan. The child's arms tightened around his neck. Father McGowan coughed.

"We're going to have some pink ice cream," he said after an interval. "Now here's my hanky. Gentlemen don't wipe their noses on their sleeves!"

"Will--will yuh bless the toad?" asked the child, after a damp smearing of Father McGowan's handkerchief. "He was a cripple. _Ain't_ he cute, now?" he added in a tender, little voice. Then he brightened and said loudly, "But I'm glad he's dead, for they ain't no Father McGowan toads to be good to little toad-cripples!"

Father McGowan coughed, and tightened his arms about Sebastiano Santo of the slums.

"Oh, dearest Paw--I mean Papa!" said Cecilia. She clung to him. The lights of the New York station blurred through her tears. Then she veered away from him, and gathered Johnny close.

"Aw," he said, "cut it! There's one of the fellows over there." But "one of the fellows" faced the other direction, Johnny saw, and he allowed himself to hug Celie quickly. He was glad to see her, but he felt a vague resentment toward her because her coming made his throat so stuffy. He remembered the time when he used to sit on her lap and eat bread spread thickly with molasses. He didn't know quite why he was thinking of it in the Pennsylvania Station.... He remembered that he used to pull her curls and that she'd pretend to cry and then kiss him, and then they'd both laugh, and laugh. It was always a great joke. And then she'd look at the clock and fry potatoes and meat over a smelly stove, and say, "Now laugh! Paw's coming home. He needs all our laughs!"

"John dear!" said Cecilia. Johnny forgot the past, and swelled. Cecilia's use of his name made him feel a man.

"Mister, will yuh please attend to this here baggage?" he heard his father say.

"Don't call him 'Mister,'" he corrected Jeremiah in an undertone. Cecilia stepped from them to a group nearby.

"Good-bye, Marjory," John heard her say. "Yes, I _will_ come to see you. You'll come to my house, too?" She turned to a rather more cool looking young person, and added less surely, "I would love to have you, too, Miss Annette, if you'd care to come."

"I'm rather busy----" John heard the Annette person reply. Then he saw her turn away from Cecilia. His heart grew hot. "If I don't see you again," said Cecilia, "I wish you the happiest kind of a Christmas!" Annette did not reply. The Marjory girl kissed Cecilia twice. "Good-bye, little Saint," she called after Cecilia. "I'm coming to see you to-morrow!"

In the motor there was a pause for inspection. "Yuh look so different," said Jeremiah rather wistfully.

"My heart is just the same," said Cecilia. "It will always be the same." She kissed Jeremiah Madden after her words and then leaned forward and kissed Johnny. He didn't mind, none of the fellows being present. Then they were silent, for when hearts are very full they are liable to wiggle up into throats and choke people when they try to talk. At last they were out of the crowded streets and on broad ones, where other cars, taking people pleasure-bent, rolled past them.

Then the house. The house from which Cecilia had gone last September, wearing a suit all over buttons, with a touch of "tasty" red here and there.

"Norah, darling Norah!" said Cecilia. Norah's red arms drew her close, then, quite in Norah's way, she eclipsed behind a blue-checked apron, and sobbed loudly. Cecilia looked about the hall. There was some new furniture. A hat-rack that was evidently the work of a lunatic with the unrestrained use of a jig-saw.

"Look up, Celie!" ordered Jeremiah. Cecilia looked up. Strung across the hall was an elaborate electric sign. The words were made of blue, yellow and red globes. She read: "Welcome to our Darling!!!" Cecilia gasped. Then she turned to her father. "It is beautiful," she said, "and just what I wanted." She stopped and swallowed with difficulty. Then added, "Papa dear, I love you so!" Johnny smiled. He raised his eyebrows and his shoulders. Then he sniffed. He thought he smelled the scent of roses.

CHAPTER VII

SANTA CLAUS

Father McGowan, holding a cassock high about his black-clad legs, stood in the back yard of the rectory grounds. The back yard looked like those photographs entitled, "Rude shelters for the soldiers," or "Huts built by the South Australian Light Horse Brigade."

All over the brown lawn were small shacks. Some of them made of brick, some of old and weather-beaten boards, and some of these two with a smattering of very ex and sticky roofing mixed in. Father McGowan smiled. Mrs. Fry looked out of the window. Her lips tightened.

A small boy emerged from one of these affairs. Emerged on his stomach, wiggling out.

"Father McGowan," he yelled, "we got a secret passage!"

"No!" said Father McGowan enthusiastically, "No!"

Another door opened. Another boy came wiggling forth. "_We_ got a secret place to hide things in, in ours!" he said in a sing-song, mine-is-better-than-yours tone.

"Aw----!" said the first disparagingly.

Father McGowan laughed. A boy came swaggering across the lawn. He whistled, "In My Harem." He touched his hat to the priest.

"I'm going to get a case of pop," he said loudly, "an' drink it here. Mom, she gimme a candle, and Pop sez I can stay out 'til nine." After this he was instantly the centre of an awed and admiring group.

Mrs. Fry opened the door. "The 'phone wants yuh," she said shortly to Father McGowan. Father McGowan went in with evident reluctance. He wanted to hear more of the case of pop, which he knew would narrow down to two bottles.

After he'd passed through the kitchen, Mrs. Fry spoke again to her sister who sat steaming by the stove. "_He's_ like that," she said, a great love, yet vast contempt, showing in her tone. "He lets all the kids around build shacks in the backyard, and even gets 'em stuff to build with!"

"What fer?" asked the steaming one. Her bewilderment was complete.

"Oh," said Mrs. Fry, "he sez something about its bein' necessary to a boy's soul to build something and tear it down. An' pretend things that ain't. One day they calls that mess of rubbish the wilds of Sieberia, an' the next an Indian camp. An' _he_, he gets right out an' chases around with 'em. He's busted his glasses twice this month." Mrs. Fry sighed. "I kicks," she went on, "and then he sez, 'Mrs. Fry, I'm sorry, but the fact is, an aunt brought me up, awfully good woman, too, but too neat. I never pounded, and a boy needs to pound.' Then he sez, 'Now if there is anything you need for the kitchen that I can get you, Mrs. Fry, I'd be glad to.' An' what can I do? I lead an awful life because of them young rapscallions, but _he_ can't see it!"

"Well, I'll be beat!"

Mrs. Fry poured out a cup of coffee and pushed it toward her guest. "Ain't sugar high?" she said as she dumped in two lumps.

"You bet," answered her guest. "Does _he_ set and study much?" she questioned. _He_ was very interesting. Mrs. Fry drew a long breath. "He don't get no time to set," she answered. "He hardly has a chance to eat half the time besides being pestered by them kids. I never know when he'll be on time for meals. Did I tell yuh about the bath-tub?" she questioned.

The steaming shook her head.

"_It has two ally-gaters in it!_" said Mrs. Fry with emphasis.

"My Gawd!"

"Yes, one of these here kids got 'em sent him from Florida, or some furrin port, an' his mother, being a sensible woman, wouldn't have 'em near. Well, the kid comes bawlin' to Father McGowan (they always do), an' he sez, 'Now, Jimmy, don't cry. You can put 'em in my bath-tub; I only bathe once a day, and I can use a tin one. Mrs. Fry has her own bath-tub on the third floor, so she won't care.' I did, but what kin yuh do? I sez, 'I won't enter that room with them rep_tiles_ in it fer to clean it.' He sez, troubled like, 'Well, Mrs. Fry, I'll do it, or get one of the boys to. I don't mind.' Them kids messing around there. Can yuh see the way _they'd_ clean it!"

"Ain't that fierce?"

"Yes, an' he don't care so much fer it, either. He sez he _could_ hope they'd die or summer'd come. (We're going to have a pond in the backyard--to run into the cellar!) Yuh oughta see that room after he's bathed in that there tin tub. All that's missin' is Noah and Shem--we got the animiles."

There was the click of crutches in the dining room. The door opened. A small boy appeared.

"Come in, dearie," said Mrs. Fry. Her tone was softened.

"What's his name?" asked the visitor.

"He don't know," answered Mrs. Fry. "He was in the hospital one time, real sick, and lately he don't remember so good. 'Father McGowan calls him 'Sebastiano.' Want a cooky, dearie?" The boy nodded, and smiled.

Cecilia had had her friend Marjory to lunch. It had gone rather well. She recalled it as she stood looking out of a heavily glassed window into a frosted street. She, herself, had set the table. The napkins had not been set up in tumblers. The fibroid tumor vase was quite absent. There had been valley lilies in a flat bowl for the centrepiece.... She had disposed of the blue glass butter dish by dropping it. Cecilia felt strangely sad as she did it. The blue glass butter dish had once seemed so very lovely.... "Are they giving me anything to take your place?" she questioned, as it shattered on the floor. Then she called Norah, and listened to her laments as she gathered up the pieces. She had the feeling of untruth added to her little sadness.

As yet nothing had taken the place of blue glass butter dishes for small Cecilia. She still preferred rhinestone hair-pins, and French-heeled shoes to their plainer sisters. Beauty had been taken away and none substituted, at least none that she enjoyed. The only thing she really cared for was the dragging of her newly acquired French in her talk. She did this often with the proud feeling that it was what her mother had wished.

Jeremiah had said, on meeting Marjory, "Pleased to meet yuh, mam," and Cecilia had broken in with, "I love papa so much, Marjory, you must too." She had hardly known why she had made this defiant and sudden declaration. Johnny had been much impressed with Cecilia's guest. So much so that his misery was acute when Jeremiah related the incident of the brick throwing.

"I sez to him, 'Yuh can lay yer own bricks an' here's one to begin with!'" Jeremiah had said with his customary chuckle, that chuckle that always came with his proud remembrance.

"I think that was exceedingly clever of you, Mr. Madden," Marjory had replied. Cecilia had smiled on Marjory with the smile of an angel, she had also laid her hand on her father's. Johnny had squirmed.

Cecilia gazed out of the window. The air looked cold. She wondered whether she would ever get the chance to thank that Mr. Keefer Stuyvesant Twombly for those lovely flowers? They had come just at the right time. He was wonderful, as the girls said, and "ravishing," but better, he was nice. There was a scuffle at the door, Norah's voice was heard: "Now mind the _eee_-lectric sign!" she said sharply. Cecilia knew that the tree was coming in.

Late that evening Jeremiah opened the door of the pink and gold "parlour."

"Santa Claus has been here and went," he said mysteriously to Cecilia and Johnny, who sat on the stairs, "an' he's did good by yuh!"

"Now remember!" said Cecilia to Johnny, with a stern look. Johnny had been told that his disbelief in Santa Claus was not to be expressed. They scrambled up. Cecilia stopped in the door. The tree was a mass of silver and glittering lights. It was really very lovely. Mr. Madden's tastes were well suited to trimming a Christmas tree.

"Showy like, an' nothing cheap or old lookin'!" he said, as he surveyed it with proud eyes. Cecilia went toward a table on which her gifts were spread out. First, she saw a phonograph with a morning glory horn.... By it was a pink velvet box, strapped in silver. "Jewels," was written in a neat, spencerian engraving on one spot of the silver banding. There was a mother of pearl brush and comb and glass, bound in wiggly gold.

"They are lovely, Papa!" said Cecilia. "And _just_ what I wanted!"

"Looka here!" whispered Jeremiah. He pulled her toward the light the tree threw and took from his pocket a small box. He opened it slowly. Cecilia saw a chain and pendant that would have made a very good showing on the Christmas tree itself. It was plainly built for one of the rhinoceros family. It had seemed to dislike showing any partiality in gems. There was a fair smattering of all jewels present.

"Three hunderd dollars!" breathed Jeremiah Madden. His eyes shone, and he breathed quickly. "Celie," he said, "it ain't too good fer yuh! There ain't nothing I wouldn't do fer yuh!"

"I know, dear," answered the small Cecilia, "but you shouldn't. It is too much. You have made me very happy." She turned away. There was a sudden smarting beneath her eyelids.... She hated the school that had taught her a quiet manner, and to see blue glass butter dishes as a visitation rather than a glory.

"That ain't _all_!" said Jeremiah. He took hold of her arm, and led her to the other side of the room. "Throw on the lights, Johnny!" he called loudly. Cecilia felt him tremble. The lights snapped on with a too white glare. Jeremiah and Cecilia stood before a picture over which was thrown a cloth. Jeremiah drew it aside.

"It was did from a tintype," said Jeremiah softly. He looked on the face of his Irish wife. Her lips were painted a brazen carmine. Her cheeks glowed like the stage ladies' of the billboards. Around her neck were three ropes of huge pearls.

"He threw in the pearls," explained Jeremiah in a voice that shook a little, "an' fancied her up some, but them eyes,--it's your maw, Celie. Your maw that died in a two-room flat." With the last words Jeremiah had turned away. His shoulders had a limp droop. The happiness of the evening had faded.

"What's in this box?" asked Cecilia, unsteadily. It was a hat box and stood beneath the new portrait.

"Her present," answered Jeremiah. "The present I give her. Look at it, Celie. Ain't it pretty? I picked it."

Cecilia opened the box. She drew out a large, flopping hat. It was trimmed with pink roses.

The next day when Father McGowan was all ready to start for the Madden house, there was commotion in the wilds of _Sie_beria. It had been reported the day before that one of the "guys" had smoked a Piedmont, and Father McGowan, finding this so, had had

to dust him mildly with a hickory cane, hung on the back porch for that purpose.

He disliked doing this, and smoked for a good hour afterward to soothe his nerves. Mrs. Fry had watched the chastising with pleased eyes, but then, on going to the bathroom, all happiness had vanished, for one of them rep_tiles_ had crawled out of the tub. She had dropped her scrubbing cloths, and disappeared screaming.

Father McGowan had been all ready to start. He had found his hat (which had the most mysterious way of disappearing), and with an ashamed expression, he'd put a small box in his pocket.

Then the wilds of _Sie_beria had demanded attention.

"Them young devils," Mrs. Fry had said, with a bob of her head backward. "They are raising Cain! Something's wrong." She went off muttering. She still cherished and resented the encounter with the rep_tile_. Father McGowan went toward _Sie_beria. It was one of the few times in his life that he hadn't wanted to.

"_Now_ what?" he called from the back porch. A scream was the only answer. It came from one of the brick dwellings. The chastised of yesterday, Father McGowan saw going quickly over the fence.

"Oh, drat!" said Father McGowan. There were wilder howls from the brick mansion. Father McGowan went toward it. He looked for the door, then he chuckled softly, for the door was entirely gone. He took off his gloves and began to pull out the bricks.

"Walled in," he muttered.

"Lemme out! Lemme out!" came from within, in muffled tones. Then with the opening Father McGowan had made, and with the advent of light, the screams dissolved into pathetic sobs.

"When I git him!" came in moist tones. A small boy wiggled out. He had a paper covered book in his hands. "He done it," explained the boy, between sniffs, "while I was a-readin' in the secret chamber. _He_ done it. When I git him! I'll smash him! I mighta starved!" he ended pathetically.

"Well," said Father McGowan, "that is a shame! Won't you come have a piece of pie now? You must be hungry."

The boy nodded. He followed Father McGowan toward the house. "He done it," he went on, "because I told on him fer smoking. I thought I _oughta_." The sufferer's tone was pious. "My nerves is shook up," he said when they reached the porch. "I was afraid I'd starve. There's pictures in our physiologies of starving Cubans--they ain't so nice.

"Mrs. Fry," said Father McGowan, "we do need a piece of pie. Could you find us some?" Mrs. Fry muttered and went to the refrigerator. Out on the back fence the chastised called, "Yi! Yi!" A note expressing scorn. He added, "Cry baby! Cry baby!" The cry baby turned and exhibited a piece of pie. The chastised relaxed into a pained silence.

"Come here!" called Father McGowan. The boy slid from the fence and came slinking toward him. "Mrs. Fry saw you smoking," said Father McGowan. "I never listen to what you tell of each other. Here's a piece of pie for you." He looked at his watch and added in a perfunctory way, "You shouldn't have walled him in."

"I ought to have given you a Rosary," said Father McGowan. He still looked guilty, but happily so. Cecilia stood before a mirror, looking at a dainty little chain and pendant, which she'd clasped about her throat.

"I know you ought, Father McGowan, dear," she answered, "but I'm _so_ glad you didn't! It's _so_ beautiful!"

She gasped happily. Father McGowan smiled. "Papa gave me one," she said. "It--it is, that is, I love it, but I'll wear this more." She looked into Father McGowan's understanding eyes.

"I am learning," she said, "but I learned things before I went to school that I shall never forget, and that I never want to forget."

Jeremiah came in.

"You give her that?" he asked in a pleased voice. "Well! But have you saw the one I give her? _Three_ hunderd dollars! Get it, Celie, and then play us 'The Shepherd Boy.'" Celie vanished.

White-clad nurses flitted about the halls of Jeremiah Madden's house. There was a dead silence, and upstairs that druggy-sick smell.

Cecilia had been very ill. She was better, but still sick enough to keep Jeremiah anxious. He hovered about the house almost forgetting bricks, and wearing a collar all the time, as he did on Sundays. It had begun with a cold, then a cough, which (through Celia's standing on the curb, better to view a gentleman down the street who was interestingly drunk) had turned to pneumonia on both sides.

She had gone to bed protesting that she felt very well, but that her breath was not acting quite right. Then she had grown so very, very sick that she had forgotten time, life and even Jeremiah of the bricks.

Those days had been rather dreadful for Jeremiah.... He had taken to sitting just outside her door on a very upright chair. He turned the pages of "Ridpath's History of the World." He was trying to "educate himself up to Celie." ... However, he missed a great many of the pictures and only got as far as Volume One.

Each time a trim nurse would step from Cecilia's door, he would cough to get his voice in shape, and then whisper gratingly: "Excuse me, Missis, but how is she?"

"She is doing well," the white one would answer, in a tone of thin sincerity. Then Jeremiah would go back to Ridpath, miserable, and unconvinced. Once in a while he would hear Cecilia's high, little voice--"Keefer, the butler!" she repeated again and again one day. She said it in gasps, but somehow got out the words. The effort in her voice had cut Jeremiah's heart, but the words had brought a proud smile.

"Associatin' with butlers!" he whispered. "_Ain't_ she gettin' fine?"

Then Cecilia moaned of butter dishes, blue ones. Jeremiah had left his post and Ridpath's History long enough to go shopping. He bought her three butter dishes. Two of them had covers. The third boasted of a curling handle, on which perched a dove and a cupid, on a spray of something that looked like spinach in the crude state. Cecilia had been very pleased with them. She had looked on them, said, "T-thank you, _dearest_!" and then cried gently, the tears slipping down her face with pathetic regularity. She cried all that afternoon.

"I'm not good enough for you!" she gasped, "but I love you, and butter dishes!"

CHAPTER VIII

A LITTLE TOUCH OF THE MAN WITH THE HOUR GLASS

Time had been careful with Father McGowan. Perhaps he thought Father McGowan rather nice as he was, and unneedful of the lines that usually come with heart and soul expansion. Be this as it may, the fact was that he was little changed. The lenses in his glasses were a bit thicker. He had accumulated a little more tummy in the last seven years, but he still played Indian and exile in _Sie_beria with the same joy, and he was still the true father to every child who knew him.

He sat behind a bare table in a room unbeautiful except for the books which lined its walls. He was looking over his mail. He laid one letter with a foreign postmark aside.

There was a tap on the door. A small boy of nine, or thereabout, came in, sobbing wildly. "My mom, she sez you're a _Catholic_!" he gasped between sobs. "Yuh ain't, are yuh?"

"I'm afraid so," answered Father McGowan. He looked very guilty.

"Oh, dear!" replied the small boy, and sobbed more loudly.

"Now, now!" said Father McGowan. "We can't _all_ be Methodists, you know. The church wouldn't hold 'em.". The child still sobbed. "I'll tell you," went on Father McGowan; "you pray that we'll all belong to one church in Heaven. You do that. Wouldn't that be nice?"

"Uh huh," agreed the boy with tempered enthusiasm. He smeared his tears across his face with his coat sleeve. They left white streaks. "I couldn't _believe_ you was a Catholic!" he said sadly. "You're so nice, and because of the pie and all." His face was long and his eyes melancholy.

"I'm sorry," said Father McGowan, "so sorry. How's Siberia to-day?" The child reported and then vanished to do his utmost in making a convert by prayer.

Father McGowan opened the rest of his mail, and then reached toward the letter of foreign stamp. He always kept the best 'til last.

"Dearest Father McGowan-dear:--" it began in a hand characteristic of many boarding schools, and yet showing a bit of individuality--"I have wanted to write you.... So many things to do that half the time all I get accomplished is my loving of you dear people, every day a little more, though more seems impossible. I love you, and Papa and John so much. So much that when I'm away from you, and think of you, I feel quite choked. It is rather beautiful, and terrible, this caring so deeply. I do not know how I could ever say good-bye."

There was a page of Cecilia's large scrawl. It contained no news, but Father McGowan read it closely. His eyes were the same as when, years before, he had looked on a table Cecilia had decorated in honour of a big, fat, Roman priest. Suddenly he laughed. "We have a small donkey," he had read, "whom we have named Clara, after the vicar's sister. Our donkey has long ears and a religious expression, too. The vicar's sister is really very nice, but our grey donkey looks so like her that we always expect her to stop in the middle of the road and talk of missionary barrels and Sunday School treats. The latter is a form of entertainment which contains much jam, tea, many pop-eyed little girls and boys, not to omit a large stickiness. (I went to one, and poured tea down Lord Somebody's neck. It was a great condescension for him to 'stop in,' and only the fact that I am of 'mad America' saved me from a public hanging.)

"Marjory and I have splendid times. I am so glad I am with her. It is nice for me, and I think for her. Mamma Aliston is one of those poor ladies who enjoys suffering. If she had lived where I did in my younger days, she would have said: 'I ain't feelin' so well. The doctor's give me three kinds of medicine. It's me _nerves_.' As this is not in order, she mutters of draughts, and places a pudgy and diamond-ringed hand above her heart many times a day, sighing expressively. Marjory has no sympathy with her. She only says, 'Don't eat that, Mamma; it is bad for you,' about anything Mamma enjoys. I am a beautiful buffer. (Please pardon the 'beautiful'; it refers to spirit.)

"The way those two people clash is utterly dreadful. I remember always, when I hear them, Saturday nights, years ago, when the gentlemen of our building used to tumble upstairs, very drunk, and I would then hear squawks and abuses. We are all the same, but people never realise it.... I laugh inside when they talk of 'lower classes.' I laugh but sometimes it hurts a little. I am ashamed, Father McGowan, that it should.... Coming home very soon. I want to give a man named Jeremiah Madden as many years of happiness as I can. I am coming home to play 'The Shepherd Boy' every evening after a lemon pie-ed dinner.

"Father McGowan-dear, I have been worried about John.... Here I see so many heavy-eyed boys slinking into manhood. Those boys who travel with their blindly indulgent mammas and leave a man at home, alone, across the seas.

"I think if my little brother should grow up to be viciously weak, I could not bear it. I cannot see how he could, for the blood in us is too plain for fancy wickedness. Rather ours would run to fierce encounter, and, if we must be truthful, flying dish-pans. But,--well, I've dreamed of him too often lately, and I remember that he may be stepping into manhood. I wish I were better fitted to be wise with him.... I have not liked his letters, Father McGowan. His estimate of people is made in the shadow of a dollar mark...." Father McGowan read another page. On the last was written: "So, I will see you very soon, dear (excuse the liberty, but you _are_ dear!), and I am ready to take up my burdens. Those that come with money. I hope to do much and learn to do it well. You will help me?

"I shall leave Marjory and her mother in this sleepy little village, shadowed by its Cathedral. The cross that has stood for peace through many years shines from its spire and seems to bring it here. It is so lovely, Father McGowan!

"Very much love from your always grateful and loving

"CECILIA."

"But, my dear!" said Mamma Aliston, "I could not _permit_ you to return alone! Could not permit it!"

"I'm sorry," answered Cecilia, "but I must go. I have my maid. I should not be really alone."

"I don't like the look of it," said Mrs. Aliston fretfully. Then, "_Is_ Clara going to sleep! Why you girls _insist_ on having her when you could motor smoothly with a footstool and cushions and all the windows closed,--Oh! My heart!" Cecilia turned a sympathetic eye toward Mrs. Aliston. "It is nothing, my dear," said Mrs. Aliston in answer to her look, "nothing to one who is _used_ to suffering. Oh,

dear, what a sorry thing this world is, when we are poorly equipped to meet it. Who was that who passed us? Not Lady Grenville-Bowers?"

Cecilia nodded and stopped Clara so that Mrs. Aliston could feast her eyes on the holy dust titles were kicking up. It was not Lady Grenville-Bowers, but Mrs. Aliston was happily unconscious of it, and Cecilia had learned the proper use of lies. After Mrs. Aliston again settled she went back to the original subject. "Let me see," she said, speculatively; "perhaps there will be some one crossing to whom it will be suitable to confide you. I dislike so intensely this running about alone,--my dear! _please_ watch that beast! Yes, more than likely there will be some one. I know so many people, many of whom some would feel privileged to know! I'll look about. I dislike so intensely this idea of your crossing alone. It is rather, pardon me, dear, common,--middleclass. Yes, I'll look about. No doubt some one may be found."

Cecilia nodded absently. She had learned to "yes" and "no" at the proper times with Mrs. Aliston, quite without a listening attention. Strangely, she was thinking of some one else beside her father, John or Father McGowan. This some one who had been the leading man of her dreams for a great many years. In fact, ever since she had rescued a sick and dying tabby.

She had carried his true voice with her wherever she went.... Often when things called men had asked for her hand because it held money, a genuine voice had echoed through the years.

"Pussy needs some Mothersills,----" she would hear, and then with an absurdly little-girl feel for being so influenced, she would gently discourage.

There had been some who really loved; some loving with an air of condescension showing through their manner,--others truly, and with humbleness. Some poor, weak, with only love as recommendation. Some just ordinary men,--one or two made big by what they felt for small Cecilia.

And with them all, something was wrong. She heard the echo of a nice boy's voice, as he bought a small girl a "choclut soda," and a sundae all-over-whipped-cream, and she heard it while she said: "No; I'm sorry. I really can't. I'm _never_ going to marry. I hope you'll find some one you'll like _much_ more than me!"

And they had all said they never would, which is the way with young men.... Cecilia had believed the first one, then life had taught her the quick healing of some hearts, and she had smiled a little when the rest said it.

That smile was always the undoing. They usually kissed the hem of her dress, and swore to shoot themselves, and Cecilia would whisper: "Oh, _please!_ Some one will see you!" or, "Oh, _please!_ Some one might hear you!" whichever the case might be. Then they always kissed her hand and went away, and Cecilia would sigh and say, "Well, I suppose that means an awfully nice wedding present soon, to show that I'm not put out!"

Sometimes she wondered if K. Stuyvesant Twombly were living, and if so, where? Then she often decided _not_ to think of him, because it was too childish.... And then she would discover that every life must have its fairy tale, and that he was hers.... "Home!" said Mrs. Aliston, with a sigh of relief. "Oh, my poor body! 'My little body is a-weary of this world.' Who said that, Cecilia? Bernard Shaw? or Arnold Bennett?"

"No," answered Cecilia, "I think it's in the Bible, but I can't just remember."

A groom stepped forward to lead Clara away to her boudoir and dinner. Cecilia went into the cool house to write her father on a small typewriter she carried for that purpose, Jeremiah being "partial to print."

Outside the grey of the English twilight crept slowly near.... Everything was peaceful,--quiet. America were far away.

The person suitable for Cecilia's chaperon was found. She was very correct, had several chins, and was well connected. She came from Boston and mentioned this fact in a hushed tone. On talking with her, Cecilia felt as she had in the first few months of boarding school--chilled, and alone.

This morning was the one before they sailed. Miss Hutchinson had wished to go to Westminster for a last look. "You will come with me?" she had asked of Cecilia. The question had really been a statement. Cecilia replied that she would be charmed to go. She went to get a broad hat that entirely eclipsed one eye.

The sun was faintly present. "It is fine," said Miss Hutchinson, who spoke English whenever she remembered it, to show that she had lived much abroad.

"So it is," said Cecilia. "How absent-minded of the sun!" Miss Hutchinson didn't answer. She was busy showing a taxi driver the error of his ways.

"Robbers!" said Miss Hutchinson, as they settled on the stuffy cushions. Cecilia looked after a passing bus, and wistfully. She dearly loved to ride on top. They bumped along, Miss Hutchinson expatiating on some one's relatives. It seemed that one of them had been "in trade."

"Papa makes bricks," said Cecilia calmly, wondering, as she said it, whether the British soaked their shoes overnight in the "bath" to get that delightful muffiny effect and the curl up at the toes.

"My dear," said Miss Hutchinson quickly, "that is quite different. His business is on a large scale, and his fortune excuses anything. This man had been in trade in a small way?--a sweet-stuff shop, I believe, or a chemist. Something fearfully ordinary."

"Horrible!" said Cecilia. Miss Hutchinson looked at her. Cecilia's smile was strange. She hoped she was not saddled with a young person of too modern ideas for seven days.... In Westminster Miss Hutchinson went toward the Poet's Corner. Cecilia wandered outside. She paused by a small stone set in the wall. "Jane Lister, Dear Child," she read. The gentle little ghost smiled on her from those simple words. She looked long at them. She always saw the "Dear Child," quaintly frocked, smiling.

Some one paused behind her. She turned. "Isn't that almost too beautiful?" she whispered.

"Yes," answered K. Stuyvesant Twombly.

He looked on this impulsive, American girl, and smiled. Then she turned back to Jane Lister, and he raised his hat and went on.

Her eyes made his memory itch, but he could not know why. Perhaps some one whom he'd met suggested her. He met a great many people.... Uncommonly pretty, if he cared for beauty,--or girls. Then his mind turned to business interests. He was supremely American.

The girl in the cloister still gazed at a weather worn slab. "Dear child," she said, "he is alive. Oh, dear child, isn't that beautiful too?"

John was faintly smiling. A superior smile that was his own and took in no one else. He used it often on the "Gov'ner," who from it, was reduced to a pulp, and realised himself fit for nothing but supplying funds.... Father McGowan was not reduced to a pulp, but he was genuinely angry. He thought with a longing of a hickory cane which hung on the back porch of the rectory.

"How old are you, John?" asked Father McGowan.

"Eighteen," replied the overgrown boy. "Gettin' on, yes, gettin' on." He lounged back in his chair. Father McGowan leaned across the table.

"Old enough to take tender care of your sister when she gets back," he said.

"Certainly," answered John. He studied his finger nails. They were gorgeous examples of the manicure's art. John wished the old man would get on. He had a date.... He wondered what he was driving at anyway? He covered a yawn and muttered a pardon.... "Late hours," he added, in explanation.

Father McGowan again thought of a cane which hung on the back porch.

"How's your father?" he asked.

"Oh,--the Gov'ner?" replied John in a tone of entire surprise. "Really, I don't know. I haven't seen him for a week." He again looked at his finger nails then he thought of a girl he did not meet socially. His thoughts and attentions ran to that kind.

"What a rotten life a priest's would be! Staying in a dull room like this--" he thought, then became conscious of a long silence. He looked up. Father McGowan's eyes were full on him.... Space faded. John was a baby in a crowded flat. He cried, and a little, tired-eyed girl picked him up. "Aw, Johnny!" she said. Flies buzzed about. The dull hum of traffic came from the street below.

Some one called, "Celie, aw Celie! Quick!" from a room off of the kitchen. The little girl vanished. He heard unpleasant sounds, then moans.

John started up. The chair in which he'd sat overturned. "You devil!" he said to a fat priest. The dream had faded. John breathed in gasps.

"I will excuse you," said Father McGowan, "if you will remember what a sister did for you, and in return give her the greatest gift: a pride in the boy she loves. Good-night, John."

After the boy had gone, Father McGowan scratched his head, as was his manner when perplexed. "What was the matter with him?" he asked aloud. Then he sighed. The talk, he was afraid, had done little good. At first he had gotten only a supercilious smile, and then that outburst.

Well, life was only a succession of tries, and a climbing at the wall unscalable.... Father McGowan dismissed the problem, thought of the comfort of a hot bath, and then the perusing of a new book he'd just bought. "Oh, drat!" he muttered. There was a baby water snake in the tub, and the tin one did not invite a lingering. It scratched in several inconvenient spots.

Outside, John still breathed in gasps. "Home," he thought as he settled in a low, grey roadster. "I don't like her hair anyway," he offered in weak excuse for abandoning his original plan. Yes, he would be good to Cecilia. Awfully good to her.... Had her life, his,--ever been as dreadful as that flash? Cecilia should never know him otherwise than she believed him. It would be a noble deceit, lived for love of her. That was the game one played with women that one truly loved.

The _Arcania's_ decks were alive with people scurrying hither and thither, seemingly with no impulse behind their unrest, nor aim in direction.

A few souls stood very calmly by the rail, watching the steerage embarking. Their whole attitudes said, and loudly: "This is all old to me. I will have you know it is even a bore!" They were looked on with respect by the few to whom crossing was a novelty.

Cecilia was pleasantly excited. Sailing was not new to her, but she was so healthily alive that she tingled with any enthusiasm near.

"Our deck chairs are in the most absurd spot!" said Miss Hutchinson. "I told the steward what I thought of him, and them. He said he would change them. Aren't you going to look at your flowers? Your state room is full of them. I stepped in. Your maid was putting some of them in your wash bowl. I told her that would never do. You will have to use it, you know, to brush your teeth, wash, and so on, and if you're sick--it is most inconvenient to have the stand cluttered with flowers. I--ah, happened to notice Lord Ashby's card on some flowers. Where did you meet him, _dear_?"

"Sunday school treat," replied Cecilia. "I poured tea down his neck." Her reply was made in an absent way. She was scrutinising the passengers. There was a fat woman near who looked lovely! She stood within earshot of Cecilia and Cecilia heard her address her husband as "Poppa," and then a very healthy and pleasantly loud-looking maiden as "Lotty." It made Cecilia feel as if she were in the warmth of a summer sun, just to hear them. So happily natural, they were.

"_Horrid_ people!" said Miss Hutchinson loudly. She elevated a lorgnette, and looked "poppa" up and down critically. "Beer, Cincinnati," she decided in far-reaching tone. Cecilia squirmed.

"That dear baby in the steerage!" said Cecilia, to divert the offended Miss Hutchinson.

"Dirty!" commented the diverted. "So absolutely degrading the way the lower classes have children! One after the other!" ended Miss Hutchinson. Cecilia did not voice it, but she wondered what other mode of entrance into the world was possible, one at a time, rarely two, having been the style for a good many years.

The baby began to whimper. Its mother slapped it vigorously. Cecilia looked away. She hated to see a child slapped. Johnny had often been most trying. She had rarely slapped him.... Then she turned and quite forgot the hot, whimpering baby of the steerage.... K. Stuyvesant Twombly stood behind her. He recognised the impulsive girl who had spoken to him at the small tomb of "Jane Lister, dear child," and he raised his hat and smiled.

Cecilia gasped. Then, she went below, and very quickly, to see her flowers.

"Oh, but you are nice," said Cecilia, "if your name is not!" Then she looked away from K. Stuyvesant Twombly. She had not meant to say anything like that! It had simply come out!

The wind blew strongly and ruffled her hair. K. Stuyvesant Twombly watched her with a good deal of interest. She was _quite_ different from any girl he'd ever met.... She watched first the rough sea which looked like a small boy's chewing gum, laid in a safe place waiting for the next chew ... grey, indented with the marks of small teeth. Then all the sea would slip below the rail, and all of the world would be sky.

"I was named," explained K. Stuyvesant, "Keefer, after a rich uncle. He died and left all his money for the support of Lutheran missions in China. After that my mother used to faint every time she'd think of my first name."

Cecilia laughed. "I'm _so_ sorry!" she said. "Does she still faint over it?"

"She died last February," answered K. Stuyvesant quietly.

"I'm so sorry!" said Cecilia again. K. Stuyvesant didn't answer. They were quiet for a few moments, both watching the tilt, and eclipse of the sky-line. At last the man spoke. "It is tragic," he said, "to have the ones you love die, but it is more tragic to have those you have loved from instinct, and never known, die. You wonder, all the time, whether they too, are fretting because of the lost opportunity. You wonder what there was below that you didn't see.... All I remember of my mother was her hurry to get in a great number of engagements, and a chill aloofness, cultivated, I have thought since, to keep in check over-tired nerves.... If we could have once gone below the surface! Even with incivilities, if in that way, we could have known each other.... Never saw one another, fleeting glimpses...."

"You poor man!" said Cecilia.

"I'm ashamed to have said that," he said. His voice was gruff. "But,--it's been in my heart these long months,--that endless regret." He drew a shaky breath. Cecilia laid her hand on his arm. Without a shade of consciousness his hand closed around hers. "I've never told any one that before," he said. "You're awfully--different. I feel as if we'd known each other always." He turned his head and looked down at her. Their eyes met, and it was hard to look away.

"You're so dear!" he blurted out.

Cecilia, used to many men of many compliments, coloured. She squeezed his hand, and then shyly drew hers away.

Mrs. Higgenmeyer came waddling down the deck. She saw Cecilia and smiled widely. "Well, dearie!" she said in her usual carrying tone, "Lotty was looking fer yuh. She and poppa are playing rum now. She wants you should see a wireless she had from her gentleman friend."

"I'd love to!" answered Cecilia. Momma passed by. K. Stuyvesant and Cecilia laughed gently.

"I like to love and laugh," said Cecilia; "but if you leave the love out, the laughter is too liable to turn sour."

K. Stuyvesant nodded, but he hadn't heard what she said. He was undergoing new and terrifyingly beautiful sensations.

"The Higgenmeyers are dear, aren't they?" said Cecilia.

"Um hum," answered K. Stuyvesant. He turned quite boldly and stared at her, while she looked out upon the sea and sky. He wondered, while he swallowed hard, whether he had any chance. He wished he weren't such a duffer! He even wished faintly that she weren't so wonderful.

Cecilia looked up at him again, and again the warm colour came into her cheeks. Then she began to talk quickly of a recent play. Her voice was not quite steady. She wouldn't meet his eyes.

Miss Hutchinson was speaking of a paper she'd read before the Boston literati on "The Message of Ibsen." Cecilia didn't know much about Ibsen, but she thought he would have been rather surprised if he'd heard what he "really meant."

K. Stuyvesant was, as usual, with them. Cecilia and he looked at each other often. The new, disconcerting light in his eyes had given way, and was displaced for the moment by a mischievous twinkle. Cecilia was able to look at him frankly again.

Miss Hutchinson arose, untangling from her steamer blanket like a huge butterfly from a cocoon. "My point was," she said loudly, "that Ibsen is the Seer of those who SEE, but," she sighed, "there are so few of us!"

She vanished.

Cecilia giggled. "Are you one of _us_?" she asked of K. Stuyesant.

"Lord, no!" he answered laughing, and then added seriously, "I'm an awful duffer. Stupid and all that. I never used to care, but now I do. You--you don't read that kind of stuff, do you?" His appeal held a great fear.

"Oh, no!" answered Cecilia. "I stopped reading improving things after I left school, I can't bear them, and it depresses me so to use my head! I'm not a bit clever." She sighed with her last words. They were both making many confessions about their failings. Somehow it seemed necessary. Also, they both wished a great deal of the time that they were much nicer!

"You know what Stephen Leacock said about intellectual honesty?" asked Cecilia. K. Stuyvesant shook his head.

"I can't quote," said Cecilia, "but he said as you grew old you would find books had brought you more pleasure than anything except tobacco. But then, he said, you must be honest about them, reading only what you liked. That if 'Pippa Passes' didn't appeal, you should let 'Pippa' pass, that she was not for you. There was some more, but I shan't ruin it by misquoting it. It was so clever!"

K. Stuyvesant didn't answer. Because Cecilia was afraid of his silences, she began to tell him of a small brother whom she greatly loved.

"But you'll know him," she ended, "if you come to see us. You will, won't you?"

"Well, rather!" answered K. Stuyvesant. "Why, you _know_ I'm coming!" There was almost a resentment in his voice. "Cecilia," he said, with his first use of her first name, "I haven't any right, but you're so _dear_, I have to. Have I _any_ chance?" He leaned very close above her steamer chair. He had gotten quite white. "Cecilia?" he whispered in question. He reached for her hand, then drew back sharply.

"I know you meet lots of fellows much finer than I am," he went on, "and when I'm away from you I don't see how I have the nerve to hope, but I can't help it. Cecilia--dear?" The "dear" was rather muffled. K. Stuyvesant had never used it before and it stuck, even though he wanted so much to say it!

She turned her face toward him, and he could say no more.

She thought of a brick on the top shelf of a gilt cabinet. "Nothing could matter to him," she thought; "he is so dear, but I must see..."

"When we get home," she whispered, "after two months you may ask me again, if you're sure."

"Sure?" he echoed. "Sure? Oh, _heavens!_" Then he looked down at her for quite a few rather breathless moments.

After that they talked. "After two months," repeated Cecilia stubbornly. It made no impression. At last she equivocated a bit and gained her point. "I hardly know you," she said, looking away from him; "I--I prefer----"

"I don't know anything about girls," said K. Stuyvesant, "but I know I've been a dub. I'll try to be agreeable, I'll _try_ to keep this to myself. But,--you _will_ give me a chance?"

Cecilia said she would.

"Gosh,--I love----" began K. Stuyvesant; then he shook his head. Cecilia didn't mean to, but she slipped her hand in his, under the kind shelter of a blue and green checked blanket. K. Stuyvesant didn't say anything more. He only looked.

Mrs. Higgenmeyer came paddling by.

"Poppa ain't so well," she called. "He's sick to his stummick!"

"I'm--I'm sorry," answered Cecilia. She tried to pull her hand from K. Stuyvesant's. He refused to let it go. After Mrs. Higgenmeyer had passed, he spoke. "You're mine!" he said in the manner of all lovers. "You are!" His voice was gruff. Cecilia was to learn that that meant that she mattered much.

At his words Cecilia's heart turned over, but she remembered her eccentric, dear, and much-loved father, and a certain brick.

"You promised," she reminded him. "I said after two months, when I knew you. You promised."

"I'll be good," he answered dismally, "but I know you, and it's hard to think of waiting. There isn't any question of time. You're just----, well, I'm thirty-two. I'd never dreamed that I could feel this. I want to kneel when I think of you. I----" he stopped.

Cecilia drew a deep breath. They looked at each other, and the world ceased for them. They were only a chord stretched to breaking,--a chord for Heaven's tunes.

CHAPTER IX

HOME

"I tell Celie, it ain't like we couldn't buy 'em perfect. (I could pay for 'em whole.) But she sez that ain't it."

Jeremiah Madden surveyed a Greek Venus as he spoke, whose arms were quite lacking. "As fer me," he went on, "I like 'em with all their limbs with 'em,--tasty and neat. This here kind of thing makes me think of the War. There's one in the Eyetalian garden I'm going to buy a cork leg for."

The young men who surrounded Jeremiah Madden laughed loudly. The loudness of their laughter made Jeremiah a bit suspicious at first, but he reasoned they would hardly accept his hospitality and laugh at him,--it must be with him. So, vastly pleased and beaming widely, he went on with pleased pride: "This here garden cost me near a million, fixings and all. That fountain to the right (the one with the dinky bird settin' on the female's arm) cost me----" but he didn't finish, for Johnny came around the corner of a path and emerged from its boxwood protection with a cough, and then a loud inanity. He frowned on Jeremiah and the laughter of the young men stopped.

"I didn't know _you_ were here," he said coolly to the quaking Jeremiah. Jeremiah realised that he had displeased, and began unsurely, "I'll be gettin' back to work. I just left fer a few minutes, I----"

"Come on," broke in Johnny, and the group of tired-looking youths followed him, leaving Jeremiah confiding to the stone "female" of his work and of how he must get back to it. Realising himself alone, he swallowed his words, and watched the group disappear toward the tennis courts with a puzzled hurt in his face.... A half a mile away, and well below, the waters of the Sound shone brazen blue in the sunlight. Sometimes a gull swooped low, and its wings were silver. In one spot a marble wall with a Greek relief stood out in blazing white against the distant water.... Jeremiah saw all the loveliness, but he could not feel it.

"That wall cost me----" he muttered, and then stopped, hearing footsteps.

Cecilia stepped from the same path from which Johnny had made his entrance. Her hat was a broad one, hiding her face provokingly, her dress one of those "simple" affairs, so dangerous to hearts and purses.

"Dearest!" she called rather breathlessly, "I did so want to see you! I've been hunting for you everywhere!" Jeremiah put his arms around her and forgot his worry about a certain son, and even forgot the cost of things.

"Well?" he questioned gently.

"Well," she repeated after him, "I just wanted to see you." She fidgetted as she had at seven, when the request for a new skillet or pan had been necessary. Jeremiah understood, and looked down at the simple affair, talking of it, to give her time. "That dress now," he said, "ain't it kind of plain? Don't you like 'em fancied up with ruffles and lace and stuff?"

Cecilia said that perhaps it was plain, but that she rather liked it. However, she would get one all-over ruffles for Jeremiah's dear gaze. After that they were silent, Cecilia staring absently out over the deep, blue Sound.

"Papa, dear," she said at last, with a gulp. "There's a man coming out to see me,--I mean us,--for Sunday. I hope you'll like him. He--he's really nice. I hope you'll like him." She stopped for a moment and then again said: "I _do_ hope you'll like him."

"Do you want me to like him?" asked Jeremiah.

"Oh, yes," said Cecilia, "I do!" She was again looking toward the Sound. Her small, white teeth were set on her lower lip. "He's very dear," she said at last; then she plaited a pink-edged handkerchief. Jeremiah frowned. "There ain't a man fit fer yuh!" he said

crossly, "not a one!"

"Yes, there is," answered Cecilia.

"There ain't!" contradicted Jeremiah. "Does he play tennis?" he questioned, "and set around in white pants?" Jeremiah's voice had grown absolutely fierce. Cecilia laughed. "I suppose he does," she admitted, "but he works, really hard. He told me that life had only meant work for him, until----"

"Hum!" grunted Jeremiah. "Hum! Let me catch him trying to keep company with you! White tennis, and pants, and gulfing around with them funny sticks! _Lemme_ catch him!"

"Don't get so excited!" said Cecilia between little giggles. "He may not even want me. He really hasn't asked me yet."

"He ain't?" exploded Jeremiah. "He ain't? _Why_ not? Is the durn fool blind? I'd like to know why not."

Cecilia sank to a white marble seat. She was laughing helplessly. Suddenly she sobered and wiped her eyes.

"Dear," she said, "do you think I'd love you less, for--for loving some one else? Didn't you love the whole world more because of mamma? It only makes me want to be much nicer, and want to hug the earth!"

She covered her face as she finished, with slender, little hands. Jeremiah sat down by her.

"I want my bonnet with pink roses on it!" she whispered, "I _do_ want it!" He put his arms around her because he couldn't answer. A gull with silver wings swooped low. Cecilia uncovered her face, and kissed the brick king. "Which is my very prettiest dress?" she asked. "I want to wear it Saturday afternoon."

She tried to think her depression came from the night before, but half of it came from the letter which she held in her hand. She had had the strangest sinking sensation on reading it, and she _did_ love Marjory. Why it had made her feel that way was a mystery.

[Illustration: THE DINNER HAD BEEN WHAT SHE WANTED]

She opened the letter again. Its pages crackled, and sprung into their first folds as she laid them on the table. The third sheet she picked up and read: "Mamma is really quite wild about travelling with the Johnstons and I am absurdly relieved. Being with that dear lady tells on my disposition (usually perfect, you know, dear!), and I am happy to say a dutifully depressed good-bye to the water bottles and ailments which are all I know of my progenitor. I told her I would come to you for the summer months, and then perhaps go to Cousin Alice. I may go home, but I'm not sure, and such a course involves the proper dowager, who is always too proper, or too improper, and ever a bore! I shall write you again about all this, and when I shall arrive.

"Dear, I shall so enjoy being with you. You are the only good person I know who does not offend me. Perhaps because you are so unconscious of that quality. Your influence is wonderful with me.... How do you like being an 'Influence'? I have turned flippant, but you know I was serious----"

And that letter, in some strange way, had depressed Cecilia. She had wanted the summer to be a quiet one,--one in which she could learn to know a small brother, have ample time to amuse her father,--and----

Well, she was utterly ashamed, but she'd wanted it alone. It was so little of her to wish it so. Marjory had been so good to her. But,--Cecilia had dreamed of quiet evenings with the moon making a glittering path of silver on the Sound.... She'd dreamed of a big, gruff man coming toward her across soft grass.... That, and the scent of roses, pink roses.... Instead the summer would be full of Marjory's friends. Marjory had so many and such gay ones! Dancing, playing cards, motoring,--hunting pleasure with a strained intensity, running foolishly so that boredom should not overtake them.... And she had needed the summer with John. Marjory, her good friend, was not the one to show him things as Cecilia would have him see them. Cecilia sighed.

Then a little spasm of pain flickered across her face. The night before was in her mind, when John, with the friends who were visiting him, had grown too joyous. She had heard them come in in the deep night. The sounds had rung clear in the still air.

The cars they drove had come crashing through rose bushes, knocking down slender trellises.... With silly laughter, she had heard the men come toward the house. There had been unpleasant words said loudly, as if such utterances were humorous. There had been more silly laughter after them.

Cecilia had felt quite sick. She had covered her eyes and made requests of some one's else mother.... Then she had slipped into a negligee and cautiously opened her door.

The hall was empty and she went to John's room. She shook as she travelled the long hall, and she hated John's friends with a marvellous hate for one so sweet-natured. She was heart-sick and afraid. John's room was empty.

She stood there a moment, steadying herself. There were pictures scattered about the room, which made her understand things more fully. One, on a table near her, showed a pert miss, with tightly curled hair, and a dress of cheap fanciness.

"Your own little girl," was written across its corner, and then the little girl's name, "Fanchette LeMain."

Cecilia turned away. She went out into the hall. She felt as she had years ago when John was her baby. At the top of the broad and long stairs she looked down. John was on the first step, sprawled unbeautifully, his head hanging limp on his chest, his hands closed around a cerise scarf on which glittered little silver spots.

She looked about to see that no one else was there and then ran quickly down the stairs.

"I'm too heavy," said John, halfway up the stairs. He had been considerably sobered by black coffee, and more so by the sight of Cecilia. He leaned on her arm.

"I have carried you before," answered Cecilia. "When we lived in the flat, that was. I used to think that when you grew up I could lean on you. It was funny how I planned."

John didn't answer. They had reached his room and he sank to his bed and sat, blinking stupidly, on the edge of it. Cecilia slipped to her knees, and began to take off his shoes.

"Don't!" he ordered sharply. "Ring for Higgens."

"I'd rather not," answered Cecilia.

"It was the heat----" he began. Cecilia sat back on her little heels. She looked like a small girl saying her "Now I lay me----"

"It was not the heat," answered Cecilia. "When you were small I washed your mouth out with brown soap for doing that. Now do you want a drink? I'll wet this towel; you'd better put it on your head. There's the dawn," she said, looking toward the window. Then she turned and picked up a cerise scarf with silver spots on it. She folded it and laid it on the table by the photograph of Fanchette LeMain. John looked unhappy.

Cecilia put her hand on her brother's shoulder. "Good-night, dear," she said. A quiver ran across his face.

"I didn't want you to know," he whispered "You're so dear, but old-fashioned. You don't understand how a man----" he stopped, and she slipped down on the bed by him. "Everything's so beastly here. I'm so ashamed to have the fellows see dad," he went on incoherently. "Always talkin' of how things cost--always makin' breaks in grammar,--afraid of his own butler----" John's eyelids were drooping. He fell back, asleep. Cecilia got up and tried to pull him into a more comfortable position. Then she went to her own room. On the way she passed Jeremiah's. She paused by his door. She wanted to kiss him,--as she had Johnny, when, very small, he had bumped himself.

"Excuse him, Dearest," she whispered. "He's very young. Some day he'll understand, I hope." Then she went on. The dawn had come. The Sound was covered by a grey fog. Cecilia lay down to stare up at her ceiling. She did not sleep again.

At last came noises. The gardeners talked as they worked on the terrace below her windows. "Cut up rough," said one. Cecilia could hear the break of wood. The white trellis with its pink rambler had evidently suffered.

"The old man----!" said another voice expressively. They laughed a little.

"Well, the kid's a gent, anyway," said the other, loudly. "Drunk every night, and enough lady friends for a Hippodrome chorus----" they laughed again.

Cecilia turned and hid her face in the pillow. Her palms were wet.

Father McGowan was surrounded by brigands. Their burnt cork moustaches gave them a fierce expression terrible to view.

"So you saw a man climbing up the grape arbor?" questioned Father McGowan.

The spokesman wriggled a little, and then said, "Well, we didn't just see him but we heard him."

"I seen him," said the youngest brigand, whose lower lip was quivering. "I seen him. He had eyes like fire. I want--my maw! I'm scared!" The youngest brigand dissolved into tears. They ran down his cheeks and through his Kaiser Wilhelm of burnt cork, leaving a grey trail on his small chin. "I want my maw!" he repeated.

"An' las' night I seen a man down the alley. He sez 'Hello Bub.' That fierce I ran home, _I_ tell yuh!" said another of the group.

"Bet it was Jack, the Hugger," came in an ominous tone from the background. The brigands quaked. Their eyes had grown large with excitement, and fear was plain above the moustaches. One small boy who wore a horse-hair imperial, muttered of "gettin' home to study his gogerfy." He, and all the rest, cast longing eyes toward the door. The youngest mopped the tears and smeared his moustache across his face with his coat sleeve.

The fat priest got up and laid aside his pipe with reluctance. "Come on," he said; "we'll go find the villain. Come on!"

Two small boys clung to his cassock,--the rest pretended a bravado. They swaggered largely through the kitchen, where Mrs. Fry, washing the rectory dishes, glared at their intrusion. Outside the soft dark covered the fears of the brigands. Father McGowan went toward the arbour. He looked well on the frail structure, and then shook it. A black cat hissed, and jumped down.

"_I_ wasn't scared none!" said the brigand who had wanted his maw, "_I_ was just pretending!" The rest of the brigands giggled foolishly and muttered of "Foolin'."

Father McGowan tactfully spoke of the weather, and then he suggested going down to the corner drug store, where pink sodas could be bought for five cents. There was a flattering acceptance of his offer. They started off, all talking loudly to him of their large achievements. He listened and answered just at the right time, and said just the right thing. So they faded into the night, the long, black shadow with the smaller ones about it, clinging to it.

"He's takin' 'em to the drug store, I bet," said a lanky boy who was smoking in the shadows. His voice was sad.

"He must say lots of Masses," said his companion. "Every time them kids bawl around his place they get something to eat."

"Um hum," agreed the first speaker, "but he ain't no soft guy. Sometimes he licks 'em fit to kill."

Down the street the drug store screen door slapped shut smartly.

"Them five-cent sodas ain't no good anyway!" said the lanky boy. "_I_ wouldn't want none!" the other sighed.

"No," said Mrs. Fry, "he ain't here. He's went to the drug store with a mess of kids. Yuh can set, or yuh can go. _He_ don't care. That's the kind of a man _he_ is."

The man who stood on the Rectory porch said he would wait. As he stepped across the threshold Mrs. Fry recognised him as a doctor who had been uppish and sent in his card, "like he was a King." She looked critically at his boots. "Trackin' in dust all the time----" she muttered. Then she went heavily down the hall, slamming the dining-room door after her.

"_He_ never gets no rest!" she stated aloud to a picture of a dead duck, hanging by its feet. "Never no peace nor no time to smoke!" She glared at the fowl which had been given Father McGowan by Agnes O'Raddle, as she soliloquised. The erstwhile Mr. Fry, who had always been forced to smoke in the backyard, was far away.

"Well?" questioned Father McGowan. The doctor who sat across the table from him leaned forward and began to speak quickly, his breath coming between his quick words in gasps: "My wife's people had the controlling interest in this plant, and I put all my money in it. It had always paid well. A ventilator, it is, which slips beneath a raised window,--simple affair, yet good. Then this Madden man got ahold of an improved article, patented it, and started a manufactory in the same town, started it on a large scale,--advertised extensively.... Well, we're ruined. We can't compete. He sells below cost. He can't want money; he's losing now. Why does he do it? We've done everything. I've offered him----"

The bell of the telephone which stood on the desk rang sharply.

"Pardon," said Father McGowan, and then, "Why, Cecilia!" There was an interval then the doctor heard him say: "Your prettiest dress? Why they're all pretty! Why?" There was a longer interval, then a sharp "What?" from Father McGowan. A silence, and then, "Dear child! I'll be out to-morrow!" Father McGowan hung up the receiver. His manner and voice were changed and softened.

"The little boy is dead," he said to the doctor. "He was happy before he died. He grew very young, and forgot a great deal, the little boy who was in your care, I mean. Now go on, tell me more of this. Will you smoke?"

The fat priest pushed a box of cigars toward the shaking doctor.

"I--I wouldn't do that now----" began the doctor. "Something's broken me. God, I've suffered! What's that?" he ended sharply. There was the tap-tap-tap that sounded like small crutches on a polished floor. Father McGowan looked perplexed.

"It must be the vines against the window," he said, "but I didn't know it was windy. Have you a match?"

The doctor nodded, and lit his cigar. His hands shook cruelly.

"God, I've suffered!" he said hoarsely, "and I believe this Madden man has caused it all. My practice and money gone, I----" he stopped. "_Can't_ you help me?" he finished. "_Can't_ you?"

"Norah," said Cecilia, "which is my prettiest dress?"

"I dunno, dearie," replied Norah. "Yuh ain't exactly homely in none! But don't go thinkin' too much of yer looks. My maw used to say, 'Beauty's only skin deep.' She was a great one fer them sayin's."

"Norah," said Cecilia, "am I--am I what you'd call pretty?"

"That depends," said Norah, "on whether yuh like dark or light hair." She surveyed Cecilia critically, her lips sternly tight, but a proud light showing in her eyes. Since Cecilia had grown up, the Virgin had undergone a complete physical transformation for Norah. If Norah's Virgin had been on earth, she might easily have been confused with Cecilia Evangeline Agnes Madden.

"How you kin set in them corsets!" said Norah, anxious to change the subject. Cecilia laughed, then turned before a long glass which stood between windows. "I wish I hadn't been educated," said Cecilia. "I _love_ pink ones, trimmed all over with roses and lace!"

"My maw used to say, 'Handsome is as handsome does!'" said Norah sternly. Cecilia's new concern for her looks and clothes was disquieting to her. She thought with a horror of Marjory's salves, and eyebrow pencils.... Suppose Cecilia!--Norah shook her head.

A maid came in the room with a froth of lacy frills falling over her arm. She disposed of the froth, then bent above the seated Cecilia, and began taking the pins from her yellow hair. It fell loosely, with the soft, slow motion of waves, about her shoulders and well below her hips....

"_Tres joli!_" said the true worshipper of beauty, as she always did.

"Nonsense!" replied Cecilia, absently, as she always did. This was the rite, frowned on by the jealous Norah.

"I mended yer skirt," said Norah crossly. "It was tore fierce."

"Thank you, dear," said Cecilia, and then: "Josephine, which is my most pretty dress?"

Norah left, shutting the door with decision. She muttered of people who talked Eyetalian, and other Heathen languages. Then she decided it was her duty to tell Cecilia of Josephine's outrageous flirting with Mr. 'Iggens. After this lofty resolve her face cleared, and her expression, became pleasant.

She passed a heavy-eyed boy in the hall. In the early days he had often shed his tears against her shoulder.... He had found love, and understanding, exhibited by doughnuts, and bread spread thickly with brown sugar.

"Mr. John----" said Norah timidly as they were opposite.

"Huh?" he responded, with a cool look. Norah swallowed with a gulp, and went on. Her heart was heavy. Her spirit ached.

"We give him too many doughnuts," she said. Then again her face cleared.

"I'll tell Celie how they go on!" she reflected. "Then I guess she won't be so smart! Winkin' and carryin' on!" The dwelling on the iniquities of Josephine was vastly cheering. Norah almost forgot a heavy-eyed and overgrown boy, who, when little, had sobbed his troubles out against her thin shoulder, and had turned to her for soothing sugar cookies.

At the pretty little station, K. Stuyvesant was met by Cecilia.

"How'd do?" he said gruffly.

"How do you do?" said Cecilia. She had on her prettiest dress, but K. Stuyvesant Twombly didn't notice it. They disposed of the baggage question and then he settled, stiff and conscious, by her side in a small grey car.

"Pretty day," said K. Stuyvesant at last. Then he looked at Cecilia. "Gosh! I love----" He stopped suddenly and shook his head.

"Wh-what have you been doing since I saw you?" asked Cecilia.

"Thinking of you," answered K. Stuyvesant gruffly. Cecilia didn't answer. He was afraid she hadn't liked his telling her the truth, so he described a futurist exhibition, while horribly conscious that the quick beating of his heart made his voice shake.

"I'm glad you came," said Cecilia after the futurist exhibition had been described. "I wanted to see you."

"Dear!" said K. Stuyvesant loudly, and without the least effort. He sat looking down on her with a very honest and revealing look, a look that would have made any one with the least feeling bet their last cent on him.

"Two months," reminded Cecilia.... It was really too wonderful. It had to be proved. If he really cared he would wait two months.

"There's the house," she said aloud, "and on the terrace my dear brother." The car twisted between tall gate posts, and the house and terrace were lost to sight from the shading trees. A collie dog bounded out from the shrubbery and barked fiercely.

"Evangeline!" called Cecilia. "He is Norah's," she explained to K. Stuyvesant. "She named him after me."

"Who is Norah?" asked K. Stuyvesant.

"She was our 'hired girl,'" answered Cecilia, "before we ever heard of maids." K. Stuyvesant didn't reply. In a second the car was by a side entrance. "John!" called Cecilia to the languid figure on the terrace. John sauntered slowly toward them.

"Glad to know you, I'm sure," he said in his most grown-up and _blasÃ©_ manner. "Nice of you to run out to see us. We get jolly bored, you know." After this John turned toward the house. There was an old man on the broad porch, looking wistfully and undecidedly toward the group.

"Oh, the Gov'ner!" said John in a tone indescribable.

"Daddy," called Cecilia loudly, "please come here _right_ away!" The brick king came toward them eagerly. "Pleased to meet yuh," he said as he acknowledged the introduction. K. Stuyvesant spoke kindly of the beauty of the place. "It ought to be beautiful!" answered Jeremiah. "It cost enough! Them there fixings fer the garden," he went on, "them alone cost----"

"Let me take you to your room," broke in John. "Don't you want to get in cooler things?" K. Stuyvesant assented and followed John to the house. When he reached the porch he looked back. Cecilia stood with her arm through her father's. She was looking up at his face. Her smile was tender.

"Gosh!" said K. Stuyvesant, and shook his head. Then he drew a long breath and turned to follow John.

The dinner had been what she wanted, thought Cecilia. He had seen _everything_.... Jeremiah had asked the butler to "spare" him a piece of bread. He had also tucked his napkin in his collar, and then, with a quick movement, removed it, looking around as he did so to see if he'd been noticed.

John had wiggled and sighed loudly when bricks had been talked of. In an effort to gloss over the crudities he had contributed a "smart line of talk," far more impossible than any amount of money mention.

K. Stuyvesant had responded politely to everything and had avoided looking at Cecilia with a studied effort. Cecilia had been silent. She felt it better that she should not appear in this act.

"He come to me, being as I was a man with money, and I sez----" came to her again in Jeremiah's cracked voice.

"I beg pardon?" K. Stuyvesant had said, having lost it through John's interruption.

"Granted," said Jeremiah. "I sez, he come to me an'----"

K. Stuyvesant had been _so_ dear! Cecilia stood leaning on the wall with the Greek relief, as she thought her thoughts.... She looked on the Sound, which was black in the night, except for a path of white moonlight. A path that quivered silver. She looked and saw K. Stuyvesant listening to Jeremiah's talk. He _had_ been so dear! She wondered whether they'd never finish their smoke and talk, and whether he'd _ever_ come to her.

Her eyes filled with tears.

"Mamma!" she whispered to the soft dark. A fitful little breeze sprang up, seeming to answer.

He came across the soft grass slowly. His heart knelt to the little Irish girl who sat upon the white marble wall.

"Hello, Mr. K. Stuyvesant!" she called gaily.

"Hello," he answered heavily. He stood, arms on the wall, a few feet from her, looking at her boldly in the soft light. The world was full of the rhythmic surge of his pulses.... The night air seemed to beat upon him with the heat of fire, but there was no thought of touching her. He was utterly humble before his shrine. He wanted, this American man of 1915, to kneel before this little maiden.... He craved the touch of her hands on his head. He was shaken, purified, thrilled.... He repeated "two months--two months!" to still his overmastering desires. The silence had been long and had grown heavy. K. Stuyvesant was afraid of it. He gulped convulsively and almost yelled: "Great night, isn't it?"

Cecilia nodded. "Don't you want to smoke?" she asked.

"I guess I'd better," he said unsteadily, then, "Oh, Cecilia!" He reached toward her, then drew back, for John came toward them.

"Cablegram," he said languidly, "for you, Celie."

Cecilia opened it. "From Marjory," she said, after reading it by the light of John's flash. "She comes next week. You must like her," she added to Stuyvesant. "She is my best friend."

CHAPTER X

"MY BEST FRIEND"

Father McGowan frowned.

"I love him," said Cecilia. "I don't care who knows it. Where's your handkerchief? I--I guess I've lost mine."

Father McGowan supplied the handkerchief. Cecilia dabbed her eyes. "You see she's so attractive," she went on, "and I'm--I'm not so very. And then John, and everything. I'm ashamed of crying like this." She gulped again. Father McGowan covered her small hand with his. "Dear child!" he said gently. "Dear child!"

The fire leaped, spluttered and hissed with capricious change. Outside the weather was grey, with a drab touch in the air. The sky was a shivery colour. Cecilia and Father McGowan sat on a wide davenport in the library.

"Where is he now?" asked Father McGowan.

"Playing tennis with Marjory," said Cecilia. She again dabbed Father McGowan's handkerchief on her eyes.

"Oh, drat!" said Father McGowan fiercely. He put his other hand over the small one which lay in his. Cecilia tightened her fingers about his thumb.

"I've been so miserable," she said, "that I've even thought of being a nun. I would if it weren't for papa, and John,--and my hair. (I couldn't bear to have it cut.) And he shows so plainly that he likes her, and then she tells me what he says,--oh, dear!"

"Darn fool!" said Father McGowan. "Is he _crazy_?" He glared at Cecilia with his question, and she laughed unsteadily.

"I'm ashamed to bother you," she said, "but it helps, and I can't tell papa. I think papa'd kill him. He's done nothing wrong, you know. You can't help what your heart does." She avoided the fat priest's eyes and looked down at her ringless left hand. "There have been lots of men," she said, "but none I could even dream of marrying. This is different, and--and I do! His eyes are so dear and so is he, but I would love him anyway. I think he's the rest of me."

"Drat!" said Father McGowan forcibly. "Drat him!"

"I wish I'd been left in the flat. Then I'd have grown up to marry some teamster. It's only when you reach for things too high above you that your arms begin to ache,--then papa and John, all the time misunderstanding each other. Both of them being hurt by this money,--and I--I _love_ him so!"

"Cecilia," said Father McGowan, "this world is full of hurts. You have to take them as you do the weather, without a question. Some one put them here to polish our little souls.... After you are fifty you will accept them with thankfulness and cease questioning. The faith of childhood will return in a bigger way, with a belief in the absolutely unknown. Some one put them here to polish our little souls. They are here, let them polish, not scratch."

"Yes," answered Cecilia meekly.

"Oh, drat!" said Father McGowan with an entire change of tone. "I don't _want_ you polished. _Dear_ child! Drat him, is he _crazy_?"

Jeremiah wandered in. He was sullen. He had been talked to by a fat priest, who told him that he should leave the discipline of a certain doctor to God and the world, explaining that it was rarely necessary for humans to add to any one's unhappiness by a mistaken sense of dealing out justice.

Jeremiah had listened with his eyes on the top shelf of a gilt cabinet which held a brick. After Father McGowan had finished, Jeremiah had spoken of the weather, and Jeremiah was a good Catholic. Father McGowan realised it was a bad case. He had abandoned it for that time.

"And will yuh stay fer dinner?" asked the sullen Jeremiah.

"I _will_," answered the priest decidedly. Cecilia handed him a handkerchief, which he folded carefully and put in his pocket. Then she got up and played "The Shepherd Boy" for the King of Bricks.

Outside in the grey light a sullen-eyed man played tennis with Marjory. He played with much energy and replied with scant courtesy to Marjory's remarks.

"Cecilia said that she was tired of entertaining,--that I'd have to do it for her," sang out the green-eyed. K. Stuyvesant's chin squared.

"In," he called. "I'm a fool to stick around," was his mental comment on himself. He was not surprised by the dead weight his heart felt, although the sensation was new.

They finished their game and went toward the house. "You're doing lots for John," said Marjory. "He adores you! Imitates your every move! You'll try to get him through this smartness?"

In truth she did not consider it smartness, for to her it was the natural attitude of young men. However she was clever enough to see the way this big, silent man felt about it, and to agree outwardly.

"I'd do anything to help one girl," he said loudly. He wanted Marjory to know how he felt about Cecilia. Perhaps she'd help him. They reached the broad steps.

"After dinner I want to see you," whispered Marjory. "In the garden,--alone. Something about Cecilia. By the white wall?"

"Not there," he answered quickly, "but by the Italian dial, if you like."

In the hall he met a fat priest. The man was heartily uncordial, but he didn't much care. After a few words he went up to his room. There he stood by his window and looked on the grey Sound. A fog was creeping over it. Everything was dismal and dull.

"I'm not much good," he muttered, "but no one could love her more. I would be--so good to her. So good. Little Saint--I----" He covered his eyes with his hands. His hands shook.

There was a tap on the door. John came in. "Hello, old chap!" he said energetically, the languid indifference all gone from his tone. "Can I stay and talk?" He settled, while K. Stuyyesant took a grip on himself, and tried to bring himself to an agreeable acceptance of his task.

In another wing of the house Cecilia was dressing. Marjory, gorgeous in a flame-coloured negligee, lounged in a comfortable chair and talked during the operation.

"You may go, Josephine," said Cecilia, "and thank you."

"If I treated my maid as you do yours," said Marjory, "she'd have no respect for me."

"If I weren't decently kind," answered Cecilia, "I'd have no respect for myself, and Josephine likes me."

"Oh, my _dear_," said Marjory, "she _adores_ you." Marjory scrutinised her nails. "I told Stuyvesant to-day," she said, "how much he'd done for John. You don't mind?"

"No," answered Cecilia. "He has. I'm grateful."

"He said he was glad I wanted him to, that he'd do anything for a certain girl. He has the dearest eyes, when he looks at you--oh, you know how----"

"Yes," answered Cecilia, "I know." There was a pause while the only sound heard was the brush on Cecilia's hair--the soft snap and swish.

"Cecilia," said Marjory, "_were_ you engaged to Tommy Dixon?"

"Yes," answered Cecilia, "but, Marjory, I can't bear to remember it. It--it was while I was much younger and hurt because of something Annette Twombly had said. I thought I'd have to marry some one like that to help papa. You know how foolish duty may be at nineteen? He was of a splendid family. I thought papa would like it, when now I know that all he wants is my happiness. After all, decayed flowers from a good plant are not worth anything."

"When did you break it off?" asked Marjory.

"When he kissed me," answered Cecilia. "It taught me how intolerable love is unless it is very true. I will always remember those kisses. I can't forget them. What are you going to wear to-night?" Cecilia changed the subject with suddenness, for it made her sick.

"Black," answered Marjory. Cecilia's heart sank. Marjory was so very pretty in black! Marjory got up. "Bye, childy," she called, "I must go." And she waved her hand airily as she went out.

On the way down the hall she repeated Cecilia's words: "I will always remember those kisses. I can't forget them." That would do very nicely for the little talk by the Italian dial.... She would play sympathy, understanding. She would not lie, but if he cared to misunderstand how could she, Marjory, help that? A sudden spark of her honest father flew across her soul.

"I don't care!" she said in answer to it, "I love him, I really do!" Then the love and trust of the small Cecilia twanged on a heart chord. Marjory shut her eyes. In her mind came those of K. Stuyvesant Twombly, as he looked when he gazed on the daughter of a "Brick King." Marjory hardened. "She doesn't love him as I do," she whispered; "she can't!"

She was only the echo of a single purpose: cruel in its selfishness, animal in its origin, and savage in intensity.

CHAPTER XI

ACCEPTANCE

"Celie, be yuh happy?" asked Jeremiah anxiously.

"Oh, yes!" answered Cecilia. She caught her breath rather spasmodically and went on: "Of course I'm happy! Here I am, all through being improved and ready to stay at home with you and John. Isn't that enough to make any one happy?"

"Don't you want some new frills, or something?" asked Jeremiah wistfully. "You know I can buy yuh anything, and I like to, good."

"I have so much," answered Cecilia. She went over to him and perched on the arm of his chair. "You and John are everything to me," she said. "When I have you I have everything!" She leaned toward him and kissed him. Her arms tightened fiercely about his neck. "You are _everything_!" she repeated loudly. 'Iggins came sliding in with that effect of being on casters, proper to butlers.

"Was yuh lookin' fer me, sir?" asked Jeremiah. Higgins assented and delivered a small box. Then he elevated his head and left. Outside the door he muttered of leaving. He recalled with bitterness his last post, where the man of the house had been a "perfect gentleman" and had thrown boots and curses at him without partiality.

"'Sir!'" he echoed with a fine scorn. "'Ow is a man to keep 'is self-respect?"

Josephine tripped down the hall. She carried Marjory's small dog, who had a scarlet coat buttoned about his small tummy. "Dee-ar Eegeens!" she purred, then fluttered her eyelashes.

"The post 'as its hadvantages," said Dee-ar Eegeens, and followed in Josephine's direction.

Inside the library Cecilia stood by a window with Jeremiah. He was untying the string of a small box and his fingers shook.

"I got it fer you, Celie," he said, "because I thought you was peaked like." He opened the box reverently.

"Oh!" said Cecilia.

"_Twenty_-five thousand," said Jeremiah. "_Look_ at her!" Jeremiah lifted his present from the box. The pendant of his present looked like a lamp shade from Tiffany's.

"_Oh!_" said Cecilia again.

"_Look_ at that there diamond and emerald and ruby all mashed together like!" said Jeremiah proudly. "_Look_ at her! _Don't_ she sparkle?"

"It does," said Cecilia; "it certainly does!"

"I told 'em to take out the pearls and put more sparkly stuff in. I sez, 'Put in all yuh can! Don't spare no expense.' I sez, 'Make her showy. She's fer the best girl on earth.' They done it too."

"Oh, yes!" said Cecilia. Her eyes were a little moist. Tears came easily lately. She put her arms around Jeremiah's neck. "Dear," she said, "I love it. I can't say thank you the way I want to."

Jeremiah didn't answer and she laid her cheek against his shoulder. Together they looked out of the window on the green and then the water's grey.

"Celie," said Jeremiah uncertainly.

"Yes?" answered Cecilia.

"Celie," he said, "you wasn't sweet on that young Twombly? You _wasn't_?" Cecilia shook her head.

"I was afraid you was frettin' over him," said Jeremiah; "you wasn't?" Again he felt her head move against his shoulder. She clung to him for a moment, and then straightened and said, "I must go dress." At the door she paused and turned back. "I love the pendant," she said. "It is beautiful. I _love_ it!"

Jeremiah beamed widely. "I knew yuh would," he said boastfully. "I sez, 'Spare no expense. It's fer my little girl that nursed her maw, cooked her paw's meals, and then learned him to wear a _dress_-suit. None smarter!'"

"It is beautiful, dearest," murmured Cecilia. Then she left the room. Alone, Jeremiah went to stand below a portrait.

"Mary," he whispered, "what makes her look like she wants to cry?"

CHAPTER XII

PAIN

"If it is any satisfaction," said Father McGowan dryly, "I will assure you that he loves you. Anybody could see that. I suppose it is your father, Cecilia."

She nodded. "Marjory----" she started, then stopped.

"Well?" said Father McGowan.

"Marjory told me he said it was--papa," said Cecilia. All the tragedy possible to feel at twenty-one was in her young eyes. "She did it kindly," added Cecilia. Then she went on unsteadily: "I don't know why I am not brave. I am so ashamed. He--he isn't worth it."

"No," answered Father McGowan, "he isn't." Cecilia slipped her hand in his. The warm contact had brought her peace at many times. It did now, in a way. "Cecilia," said Father McGowan, "sometimes love means pain. You know Father Tabb's poem about it?"

"No," said Cecilia.

"Once only did he pass my way 'When wilt Thou come again? All, leave some token of Thy stay!' He wrote (and vanished) 'Pain.'"

Cecilia tightened her fingers about Father McGowan's thumb. "You have always been so good to me," she whispered. "You have always understood and helped me!"

"Well, well!" said Father McGowan. "What else am I here for?"

"Marjory said if I kept papa,--kept papa----" Cecilia stopped.

"Kept him in the backyard or in the cellar, it would be better?" ended Father McGowan.

"Oh, _don't_!" said Cecilia. "Please don't; for two or three times I've felt like John,--I'm _so_ ashamed."

"Dear child!" Father McGowan said. "Dear child!"

"I love papa," said Cecilia. "It's only this new feeling that unsettles me. Sometimes I think I'd pay any price. Sometimes, like John, I'm ashamed, and then how I _hate_ myself!"

A gilded moon had slid from behind a line of poplars. It had shown Father McGowan eyes that reflected an aching soul, tragic young eyes, almost bitter in their hurt.

Suddenly Cecilia held his fat hand against her cheek. Then she smiled at him bravely. "I'm going to be good!" she said with a little catch in her voice. "I'm going to be good!"

"Cecilia Evangeline," said Father McGowan, "dear child!"

Marjory entered the room with a slam and a swish. "I telephoned Stuyvesant and asked him to come out to dinner," she said. "You don't mind?"

"No," answered Cecilia, "certainly not."

"He seemed anxious to come," said Marjory consciously. Cecilia didn't reply.

"What's in that box?" asked Marjory.

"A present," answered Cecilia. She took it from the box and held it up for inspection.

"Oh, Lord!" said Marjory. "Your father?"

Cecilia again did not reply. Her cheeks were pink and her eyes sparkled.

"If I were you," advised Marjory, "I wouldn't wear it to-night. You know how conservative the Twomblys are----"

"What he thinks is not vital to me," said Cecilia. "I shall wear it. I _love_ it. I think it's beautiful!"

"You dear child!" said Marjory. She looked on the small liar with respect. Suddenly she was shocked into speechlessness. The small liar was sobbing wildly.

"Oh, Marjory! Oh, Marjory!" she gasped.

Much later Cecilia stood at the foot of the broad stair.

"Where's your necklace?" asked Jeremiah.

"Oh," said Cecilia, "I forgot it, but I want to wear it. I do! I'm going to get it now." She turned from him and ran up the steps.

"Here he is!" she heard John call from the porch. Then came Marjory's loud laugh. Cecilia's breath came fast, and her fingers trembled as they clasped the new necklace about her throat. She stood before the mirror a minute before she started down. "It _is_ beautiful," she said, "and I am proud to wear it!"

That night Cecilia lay long wakeful. She had not slept much or well lately. She heard the different clocks follow each other with minutes' difference in their chimes. Hour after hour.... Cruel hours.... Control left her and she turned from side to side, restlessly moving into what seemed, each time, a more restless position.

She hoped K. Stuyvesant had believed her when she said she thought her new necklace beautiful. She remembered John's sneer and his question: "Been shopping at the 'Five and Ten'?"

Best, she remembered Jeremiah's proud pleasure in his gift. The remembrance hurt, and made her feel little.

There was a tap on her door which made her strained nerves leap. She sat up in bed and turned on the lights, blinking in their glare.

"What is it?" she called.

"It is I," answered Marjory. "I've been wakeful. I want to talk with you for a moment."

"Come in," said Cecilia. Marjory opened the door and came across the room to sit on the edge of Cecilia's bed.

"I'm sorry you haven't slept," said Cecilia.

"That doesn't matter," answered Marjory. Cecilia saw that she was very tired, so tired that she looked old. She was the Marjory of gay evening, with a grey veil shrouding her.

"I'm going away," said Marjory abruptly. Her fingers played with the coverlet and her eyes avoided Cecilia's. "I'm going back to mamma," she continued. "I think she needs me, and--and I _hate_ the States!"

"Marjory, _dear_!" said Cecilia, "I'm sorry--so sorry."

"No one wants me," said the new Marjory. "I only make trouble wherever I go. No one wants me----"

"I always want you," said Cecilia. "I do, Marjory,--I really do."

"I believe you really mean that," said Marjory slowly. "I'm almost too little to understand you, but I know you never lie."

"I lied about the necklace," said Cecilia; "I don't think it beautiful, except for the love it shows."

"Cecilia," said Marjory, "I can't be truthful. I can't, Cecilia----"

"Don't!" answered Cecilia. "You are! I know you better than any one. You have been my best friend always, and I say you are!"

Marjory's fingers plucked at the coverlet restlessly. She breathed in quick gasps. Cecilia laid her hand on Marjory's. "Perhaps to-morrow you'll feel differently?" she suggested. "You know dark makes things so much darker. I'll do anything to make you happier. I'll ask Mr. Twombly to come out and play with you often, Marjory dear."

"Don't, oh, don't!" whimpered Marjory. Her shoulders shook. Cecilia closed her eyes a moment, and then spoke quite loudly and steadily. "Dear," she said, "I'm sure he loves you. I'm sure he does."

"Don't!" implored Marjory. "Don't!" She threw back her head and spoke in a different tone. "I hate America!" she said viciously. "I hate everything! Life, my place in it. I hate you for being so good! I hate,--oh, God! Oh, God!" Her tirade ended in a paroxysm of dry sobs. Small Cecilia reached out her arms and drew Marjory's head against her soft bosom.

"Oh, dear Marjory!" she whispered, "you have been so good to me! I would do anything to make you happier! _Anything!_ Marjory, dear Marjory!"

Marjory sobbed on.

"I wasn't worthy of my dreams," Cecilia heard her say between gasps. "I--they were too big for me. I knew it, but----" she stopped. Cecilia, all uncomprehending, baffled, said only, "Dear!" and again, "Dear!"

Some strange trouble this was to bring tears to the dry-eyed Marjory, but Marjory needed comfort, not questions. "Dear!" she said once again. Marjory drew away. "Oh, heavens!" she said, laughing, "what an emotional actress I could have been. Forget this and sleep; I shall." She stood up, stretching. Suddenly she was again the new Marjory. She looked on Cecilia. "I _did_ try," she said, "and some people can't be decent even when they try. They can only get halfway."

"What?" began Cecilia.

"Nothing," said Marjory. "Good-night." She started for the door, and then turned back. She leaned above the bed and kissed Cecilia rather fiercely, quite as if she thought of some one else whom she loved in another way while she did it. After she'd gone Cecilia hid her eyes. Without reason the kisses of Tommy Dixon were recalled. Those of the life-half, without a touch of soul. Then Cecilia forgot them in her wonder about Marjory.

"I would do anything for her happiness," thought Cecilia, "even that." And then she closed her eyes and asked to be strong.

When she opened them she saw a golden streak across the floor. The sun was up.

CHAPTER XIII

A REQUEST

"Miss Cecilia----" said Stuyvesant Twombly into the telephone which stood on his desk. His heart hammered so that his ears ached, and the furniture in the room swayed and bent.

"I want to ask you a favour," he heard. "It matters a great deal to me, and, well, to----" she stopped.

"Yes?" he said, aware that his voice was crisp. He had not meant to have it so, but his voice, when Cecilia was near, did as it pleased.

"It's about John," he heard her say very quickly. "He--you know he cares a great deal about you, and that you influence him greatly. You did more than any one else ever has for him."

"I'm sure," interrupted K. Stuyvesant, "I'm glad. I don't mean that," he blurted out; "I mean----"

"I understand," said Cecilia; "I telephoned you to ask you if you wouldn't come to the house sometimes because of him? I--I'm not home very much. The--the little incident of the boat is quite forgotten----"

K. Stuyvesant coughed.

"I understand you," said Cecilia. "I hope you do me?"

"Yes," answered K. Stuyvesant miserably.

"You will help him?" she questioned further.

"I will," he answered. "I told Miss Marjory I'd do----

"Yes," broke in Cecilia, unable to bear more; "she told me what you said. I'll be more grateful than you can ever know, too."

K. Stuyvesant swallowed convulsively.

"Good-bye," she said in a small voice. "Good-bye," he answered gruffly. He hung up the receiver and stared across the room. His teeth were set with cruel tightness on his lower lip.... He remembered how her little hand had crept into his beneath a blue and green checked steamer blanket. He almost wished he could forget it.... And that distance at which she'd kept him had not been

what he'd thought, her proving of his sudden love, but only her inclination. Lord, how he'd dreamed, and still dreamed! ... He'd do what he could for John. He believed much was possible.

And how even the sound of her voice left him! Shaking, and aching with his want. First hot, then cold.... He stared, unseeingly, across his office. He recalled his first evening at the country house when he'd stood by the white wall with a Greek relief, worshipping a little Irish maid.

Then Marjory had come. He wished she hadn't. He almost hated her, and found no reason why he should, except for her telling him something which haunted his long nights.... "Cecilia, Cecilia!" ran through his head,--and heart.... For her, he'd do what he could for John. He reached for the telephone and called a number he knew too well. After an interval, and a request, John answered.

At first his tone was languid, then it leaped into colour from pleasure, and K. Stuyvesant hid his eyes.... John, genuine, echoed the dearest Cecilia. His voice, even in its grating boy-quality, held a hint of hers.

"Then we'll go riding?" K. Stuyvesant asked.

"I'd be jolly glad to!" answered John. "I've wanted to see you, but I thought I'd better not bother you."

"We'll take in the aeroplane show," said K. Stuyvesant, "if you like." John liked very much. He hung up the receiver, looking like a boy. His thickened eyelids were lifted, his eyes wide open.

Looking toward the photograph of Fanchette, he recalled an engagement. "You may go to hell!" he said loudly, not stopping to think that his staying away would not send her there; but that she was more liable to its admittance on earth, if he, and other idle young men of his stamp, were with her.

The aeroplane show! That would be great! Of all the chaps he'd ever known he most admired K. Stuyvesant, and to chum with him! Well, wouldn't the fellows look! Well, rather!

In the hall he passed Jeremiah. "Going out with Stuyvesant," he called pleasantly. Confiding his intentions or aim in direction was unusual. Both he and Jeremiah wondered at it. Jeremiah was so pleased that he was past smiling. A little quirk came in his heart, and he whispered, "Just then he looked like Mary used to when I brung her the wages. He did! I wished she could have saw him!" Then Jeremiah went on down the hall, stooping a little more than usual, as he always did with the thought that made him old.

"A bunnit with pink roses on!" he muttered next. That always came with his memory of Mary, that "bunnit" that she never had.

"Hello, Madden," said K. Stuyvesant. John threw out his chest. K. Stuyvesant had acknowledged him a man. "How're yuh?" he added. John said that he was well. As they spoke they sped away from the stern-faced houses of New York's moneyed folk and into its hum.

"Glad to be in town again," said John; "awful glad to see you too. Got beastly quiet out there after Marjory left. Can't be sleepy while _she's_ around!" K. Stuyvesant assented.

"You mashed on her too?" inquired John. K. Stuyvesant took his eyes, for the faintest second, from the street ahead. Then he looked back. He had answered. John felt limp, and adored with more fervor. "Didn't mean to offend," he muttered.

They had spent a pleasant afternoon. At least John thought so, the pleasantest, he thought, for ages, but just now he was suffering from a profound shock. K. Stuyvesant had said something that had left John mentally holding on to his solar plexus.

"You say it's an evidence of _youth_ to get drunk?" said John.

"Uh huh," answered K. Stuyvesant in an indifferent tone. "Surest sign in the world that a fellow's about nineteen. You know how it is, a chap wants to get old, be thought old, so he imitates what he thinks is manhood. Like a kid, picking out gilt instead of gold, he picks out a drunk, and thinks it's a man. Look at that motor! _Some_ peach!"

"Yes," agreed John absently. However he hadn't seen the motor. He was hoping with violence that K. Stuyvesant had not heard of his lurid past. For the first time he thought of his "past" without pleasure. Heretofore his "past" had been like a treasured museum. Each piece of fresh wickedness added to it with great pleasure, and the knowledge that its value was greater.

"Everybody goes through that stage," said K. Stuyvesant, quite as if he'd read John's mind. "It's the measles of the pin-feather age. Look here, John, whatcha think of that shaft? Looks kinda heavy to me."

"Hollow, aluminum," said John in a little voice. He was suffering from a complete emotional turn over. It was difficult to contemplate shafts. K. Stuyvesant fingered a frame with interest. "Like to own one," he said, "darned if I wouldn't!"

"Keep yer hands off them machines!" said a loud voice, the owner of which glared on K. Stuyvesant. K. Stuyvesant removed his hands. He also smiled. John was nettled. His great dignity was hurt.

"Why didn't you tell him who you were?" he asked of Stuyvesant with heat.

"Oh, Lord!" said Stuyvesant. "Why should I? The fact that I draw a little more on pay day than the next fellow doesn't give me the divine right to paw all over the works." John was silent. He was again mentally steadying his solar plexus. The afternoon had been full of earthquakes to his small ideas, and reconstruction.

"Look here," said John seriously, "did you go through that period?"

K. Stuyvesant looked sheepish, then he laughed. "Sure," he said; "I was a real devil at twenty. I couldn't stand girls because I thought they laughed at me, so I decided to drink myself to death. My proud ideal was to be the heaviest drinker in New York, and to be so pointed out. Sometimes I stayed out as late as two."

John laughed with him, although his inclinations were far from laughter. Coarse hands were despoiling his altar, and, worse, laughing at it, as an echo of childhood.

K. Stuyvesant had seated himself on a folding chair that smelled of a hearse. John settled by him. "These chairs always make me think of Uncle Keefer's funeral," said Stuyvesant. "Mother went, draped in eighteen yards of crape. She mourned him deeply until she heard the will, then she tore off the weeds and had 'em burned."

John was far away, so the subject of Uncle Keefer's funeral was abandoned.

"Did--did you collect girls' photographs?" asked John.

"Girls never liked me," said Stuyvesant, "and guns weren't allowed. I did use to have a gallery of second-rate actresses decorating my boudoir. I bought the pictures at a photographer's. The less they wore the better. Lord, what a calf period! Hiccoughing, little asses! Makes me sick to think of it!" Real disgust was written on K. Stuyvesant's face. John pushed his hair away from his forehead. He felt very hot. If some one else had spoken, he would not have noticed. But K. Stuyvesant--chased by most of New York! Honestly liked by the fellows, as a good sport. Owner of several cups for several achievements. Rated as "damned indifferent, but a bully chap!"

John felt weak and little,--worse,--he felt terribly young. He looked away from K. Stuyvesant. Perhaps K. Stuyvesant sensed something of his misery, for he laid a big hand on John's shoulder. The hand was cheering.

"Where you going to college?" he asked. John explained that he had not thought of going, that he hated work, and that a certain amount of study seemed necessary for school.

K. Stuyvesant talked persuasively. "If you studied this winter you could enter next fall," he said; "you have all of the year to do it in. I'll look up some decent tutors, and help all I can, but I'm darned stupid, myself. Wish I weren't. All I could do would be to root. I'd do that!"

"Would you kind of help me keep interested?" said John, looking at his feet. "I haven't done anything that I haven't wanted to, for so long, that I've lost the knack. If you'd help me keep interested,--will you?"

"You bet I _will_!" answered K. Stuyvesant.

"Thank you," said John quietly. K. Stuyvesant's hand tightened on John's shoulder convulsively. Then he took it away. Cecilia's voice had seemed to say the little "thank you." He was shaken, and vastly relieved when John began to talk of monoplanes. He wondered with dull misery if all his years would be full of this "where is the rest of me?" feel. "Why isn't she here? _How_ can we be apart when I feel like this?"

He looked at John. The monoplane essay had ceased. "How is your sister?" asked K. Stuyvesant gruffly.

"Cecilia," said John, "I wish you'd come in." He was by the door of his bedroom as he spoke. Cecilia answered that she'd be happy to come in, and stepped past him. "I'm going to college," said John dramatically after he'd closed the door. "Stuyvesant wants me to. He thinks he can get me in his Frat. He's going to buy an aeroplane, but he says I can't go up unless you say so. Can I? Are you glad I'm going to college?"

Cecilia was entirely bewildered, but said she was glad he had decided to go to college. She sat in a low chair by a table, and her bewilderment increased when John took several photographs from his bureau and threw them carelessly into the waste basket. Next she saw Fanchette thrown in a table drawer, which was then slammed.

"John dear," said Cecilia, "_are_ you sick?"

"No," answered John, then she saw a twinkle in his eyes, often there in the little boy days. "I'm Irish," he continued, "and I can see a joke, even on myself. I've tried to be very old, Celie."

She put her arms around his neck. He hid his face against her throat, and she felt him shake. The joke was forgotten. "It's so hard," she heard in muffled tones; "I'm ashamed of dad, and then I try to gloss it over, I----"

"If it hadn't been for dad," said Cecilia slowly, "we would have both been getting slabs of peat out of an Irish bog, surely barefooted, probably hungry."

"It would have been better," said John bitterly.

"Perhaps," answered Cecilia, "but that is not the question. We're here."

"Quite so," said John, and laughed a little. He had drawn away, ashamed of his emotion.

"Have I seemed like a kid to you?" he asked.

Cecilia looked at him squarely. "Yes," she answered.

"Why didn't you help me?" he blurted out. "Let me be the laughing stock of every one. The son of a multi-millionaire, the laughing stock of----"

"If you recollect," interrupted Cecilia, "I did try. More than once. You told me I was only a girl, that I didn't understand. You even told me to mind my business on several occasions."

"Oh, Celie!" said John.

"Dear!" answered Cecilia, in another tone. She sat on the arm of the chair in which he'd thrown himself. He put an arm around her.

"Now that you are awake," said Cecilia, "what do you think of those near-men you've been introducing me to all summer?" She was smiling. John's inclination to anger vanished. He smiled foolishly instead.

"The mixture is the trouble," he said, "with no one whom you can respect to guide you,--no power above. I feel better, naturally, than the Gov'ner."

Cecilia let that pass. "Orchids and hollyhocks in one bed," she said, "but in time I believe you'll come to love the homely honesty of hollyhocks,--those that thrive in all weathers. I believe you will, John. I do."

He got up and stretched. The new man had gone. She saw this, and rose with him. "Good-bye, dear," she said in a very everyday tone; "I'm glad you had a good time this afternoon."

In a flash he changed again. His arms closed about her soft body, and he kissed her. "Celie," he said huskily, "you're the _best_ fellow!"

"Johnny," she answered, "you _darling_!" He gave her another squeeze, and released her. Then he was again the conscious boy. "This darn tie," he muttered, looking in a mirror; "it wads up rottenly!"

Cecilia left indifferently, but outside his door she turned and kissed a panel opposite her small head.

She wore the want-to-cry expression which so worried Jeremiah, but her eyes were happy. They looked like those of a little girl who holds the best beloved, just mended, doll, all fixed up, ready to love and spank some more, to scold, forgive, and kiss.

CHAPTER XIV

PINK

"You are an advocate of gum-chewing?" asked Miss Annette Twombly, with a faint, not too pleasant smile.

"No," answered Cecilia, "but I do think we ought to give them a good time, not reform them. Why, they get discipline all day at their work. I wanted to make them forget that, and all their imperfections." She turned with the words to glance about the group of young women who sat in the office of the Girls' Club.

There was a vague murmur. "But--gum--!" Cecilia heard in a voice which held horror.

"My idea," said Annette, in her cool, slow voice, "was to give them higher ideals, and to teach them not to wear those horrid, pink silk blouses, you know. Teach them that it isn't nice to chew gum, and,--ah,--well, give them a _larger_ life."

"How are you going to give it?" asked Cecilia. "I see what you are going to destroy, but what are you going to put in their places? I think a certain amount of pink is necessary. It has to be _very_ bright, for there is so little of it. It has to reach a long way."

Annette didn't think this worth answering. She simply raised her shoulders and eyebrows in a gesture denoting suffering tolerance and pity. Then she turned to a neighbour and spoke in an undertone. They laughed, and Cecilia flushed.

"Are you an upholder of the green velvet 'throw' on the parlour organ, Miss Madden?" asked a young woman, noted for her bizarre dress.

"I am when the green velvet is the only possible beauty for them,--the only reachable one. I think it's so narrow," she went on heatedly, "to make them enjoy themselves just in our way,--to inflict our likes and dislikes because it's possible to do so. I want to give these girls what _they_ consider a good time, and what they want. Patterns for good times differ. I want dances instead of classes in art. They need them."

"But, my dear,--gum, and those fearful frocks! Annette meant to tell them not to wear cheap laces, but to dress plainly, and suitably to their station," explained a drab young lady whose own dress looked as if it had been designed for a futurist ball.

Cecilia sighed. She saw a band of heavy-eyed and tired-out girls denied their little cravings for beauty. She saw them laying aside pink blouses which brought a faint pink into their small, starved souls. She saw them trying to be ladies, and losing the little solace of "spear-mint gum," and roses of cabbage size and architecture on their cheap hats.

"I think they need the pink," said Cecilia. "If their dress is criticised I think the Club is failing in its mission. Every one will criticise them, few will love them. Let's leave their manners and their dresses to their own management. Let us just try to make them forget the factories, and the flat crowded full of children. I wanted to give them a place where they could bring their beaux."

"We agreed about the dances," said Miss Twombly; "I shall _adore_ coming to them! Won't they be _killing_?" A hum of voices followed this, in which was heard: "But their horrible frocks!"--"In the end they would thank us!"--"Give them a vision of a larger, more helpful life!"

"I shall not subscribe to a reformatory," said Cecilia loudly. She hated to say it, but an echo of some one who had wanted a "bunnit with pink roses on" flew before her. She meant to do all she could to help other people get, and keep, their particular brands of pink roses.

Cecilia's contribution for the club's maintenance was large. It was agreed that for the present at least no helpful hints as to the bad taste of its members' clothes should be given. Cecilia looked at a small watch, and got up. She said good-bye pleasantly. When the door closed after her there was a surge of noise.

"Well," said Annette in a carrying tone, "of course she _would_ sympathise. I suppose her own tastes are really theirs. _Have_ you ever seen her father?"

"She plays 'The Shepherd Boy,' and 'The Storm in the Alps' for him every evening," said the bizarre.

"My _dear_," said another, "_have_ you seen the boy? He is _really_ quite possible and they say that the horrible old man is fabulously wealthy too."

"Criminal!" breathed Annette. Her eyes were angry and full of resentment.

"Annette," said a girl from across the room, "how are you getting on? I think it's too original of you!"

"You aren't still doing that?" asked another. Annette nodded.

"What?" asked a bewildered onlooker.

"Working, really work," she was informed.

"My _dear_, how sweet!" said the informed. "Isn't it ennobling, and broadening, and all that kind of thing?"

Annette nodded, and then spoke flippantly of it as a "lark." Her bravado was a bit too thick. Several young people who knew something of Mrs. Twombly's investments looked at each other across Annette's head.

After she left there was another free discussion. "Social secretary," said the drab one, "to a horrid person from Ohio, or the state of Washington, or somewhere terribly west. Trying to break in, lots of money, but oh,--like the Maddens."

"Hasn't Stuyvesant a huge fortune?" asked the bizarre. "Why doesn't he help then? Though his not doing so is quite what I'd expect. I tried to be so pleasant to him on one occasion, and he was absolutely _rude_! Really rude! He said----"

Cecilia had stopped at Mrs. Smithers' on her way home. She sat by the stove holding the latest Smithers on her lap.

"We got it with tradin' stamps," said Mrs. Smithers. She held up a purple vase which had evidently been created by some one suffering with a toothache. Mrs. Smithers was trying not to smile. She felt that she should be easily careless with her new grandeur, but it was hard to be so. "Look at that there seascape," she said, turning the seascape side toward Cecilia, "an' that there sailor with his girl. Ain't she purty? My old man, he sez if he seen one like her, he wouldn't come home no more!" Cecilia joined Mrs. Smithers' loud laughter over the "old man's" subtle humour.

"Two books," Mrs. Smithers explained after the laughter had ceased, "an' next time we're going to get a plush photograph album. It has a mirror-like on top, with daisies and I dunno what all painted around. _Hand_ painted on that there velvet, mind yuh. It's _swell_!"

"I imagine it is," agreed Cecilia. "You like to have pretty things, don't you?" she questioned.

Mrs. Smithers' wide and fat face clouded. "Dearie," she said, "yuh gotta have gilt an' fancy vases to make yuh ferget how homely most life is. I wish you could have saw me yesterday. My Gawd, I get tired a-doin' the wash, an' Jim so tony, him usin' _two_ shirts a week! Well, I didn't mind the sweatin' all day, the way I do over the wash, f er all I seen was that there vase a-settin' there. Now ain't it purty?"

Cecilia agreed that it was. Mrs. Smithers smiled again. "Why," she exclaimed, "I nearly forgot Lena's dress--the one she's going to wear to the club dance. She set up 'til one last night a-fixing it. She was tickled to fits about it. Looka here." Mrs. Smithers reached below the dining table and took out the third box from the bottom. She opened it reverently. It disclosed a dress of cheap and flimsy lawn, made in the most extreme of styles. There was black velvet on it, several bales of lace, and some roses. Its colour was pink.

"How lovely!" said Cecilia, and she meant it; for Cecilia saw what the colour meant,--what it brought,--and the dress to her was truly lovely.

"Yessir," said Mrs. Smithers; "Lena, she sez, 'Maw, I feel like a queen in this here!' (she's partial to pink) an' yuh oughta see her in it. Mebbe she ain't purty. Her gentleman friend, who works at Helfrich's delicatessen store, cold meat counter, yuh know,--he sez, 'My Irish rose,' when he seen it. That's a song, 'My Irish Rose.' The Kellys got it on the graphaphone. It's swell. Ever hear it?"

Cecilia had not.

"I wish she had a pink hat," said Mrs. Smithers, "an' then she could wear this to church. First Luthern, we go to,--that one with the fancy brick, corner of Seventh, and----"

"I have a hat," said Cecilia, "that I'm going to send to Lena. It's pink, and it has lots of roses on it!"

Tears came to the little eyes of Mrs. Smithers. She beamed widely. "I didn't mean fer to hint," she said; "honest to Gawd, I didn't."

"I know," answered Cecilia, "and you know I love to send Lena things. Is she still coughing, and is she drinking the milk I send?"

"Yes," answered Mrs. Smithers, "but she don't just like it. She likes evaporated better, bein' used to it." Mrs. Smithers looked doleful. The mention of Lena's cough always made her so. Her expression was like that of a meditative pig, for her small eyes and fat face together provided everything but the grunt. However, to Cecilia she was beautiful, for Cecilia saw the love in Mrs. Smithers' soul, which she spread around her seven children and the "old man."

"I won't forget the hat," called Cecilia from the doorway, "and it shall be _very_ pink!"

"Miss Madden, meet my gentleman friend." The gentleman friend shuffled his feet and emitted a raucous "Pleased tuh meet yuh."

It was the night of the first dance at the Girls' Club. Little knots of its members stood around the edges of the floor, laughing often, and loudly. The gentlemen friends seemed to spend their time deciding which foot to stand on, and then shifting to the other.

The committee of "uplift workers" rushed around wildly, doing nothing. It was notable that Cecilia was the one to whom the "gentleman friends" were introduced.

Lena Smithers came up to Cecilia. "That hat," she said, "I dunno how to thank yuh! Paw, he's talkin' alla time about them roses. They're grand!"

"I'm glad you liked it, dear," said Cecilia.

"Yes," went on Lena more shyly, "an' my gentleman friend, him who clerks at the delicatessen, he likes it too. Honest, that boy's grand to me! They ain't hardly an evening that he don't bring me a string of sausage or a hunk of ham!" Cecilia looked impressed and murmured, "Really?"

"Um hum! Gawd's truth!" said Lena.

"Mr. Ensminger," said a fat girl, towing a flaxen-haired boy with no chin. "Soda fountain clerk to the Crystal. Better kid him on, Miss Madden, mebbe he'll give yuh a soda!"

There was loud laughter at this persiflage. Suddenly Cecilia forgot it, her surroundings, the gentlemen friends, in fact everything but the cruelly fast pumping of her small heart, for across the room she saw John coming in, and by him Stuyvesant Twombly.

"How did Mr. Twombly happen to come?" Cecilia asked of John much later, when they were dancing.

"Why," answered John, "I told him of it, and he said, 'Let's go down. Would your sister mind?' Of course I said, 'No.'"

"Of course," answered Cecilia.

"Who's the girl who dances like a duck with the rheumatism?" asked John. "She walked halfway up my shins, got discouraged, gave it up, and then later started it all over again."

"Sweet persistency," murmured Cecilia. Her eyes were on the partner of the duck with the rheumatism, K. Stuyvesant. He looked warm.

The music stopped. Cecilia and John found themselves with the duck and her partner. K. Stuyvesant stepped toward Cecilia with determination. "Will you _please_ give me the next?" he said. His request was made in a desperate tone, a tone absolutely unsuitable for the asking of a dance.

"Why," said Cecilia, "there are so many girls here who sit about. I have to see that they have partners, and----"

"Oh, go on!" broke in John. "You dance; I'll do the proper for you." K. Stuyvesant put a hand on John's arm; the touch was full of gratitude. Then the music started in a slow, sentimental, sweet waltz song, popular that season. K. Stuyvesant invented several new steps. It was good that Cecilia was an unusual and adaptable dancer, for his tempo and intentions were mixed. "What is this?" he asked at last.

"A waltz," answered Cecilia, and at that he stopped his mixture of one-step and maxixe. "Excuse me," he said gruffly. Beads of wet stood out on his forehead. He was out of breath.

"Would you like to stop?" asked Cecilia. "It's warm and you seem tired."

"Oh, no!" he said passionately. She looked up at him, and when their eyes met his arm tightened with a spasmodic quickness about her; then he turned a deep mahogany colour and stared unseeingly across her head. He had not meant to do that. He wondered what she'd think of him.

As for Cecilia, she shut her eyes and tried to be indignant. It was an insult, an insult when he felt as Marjory said he did, an insult! But oh, how sweet, how sweet!

The music stopped. "Thank you," said K. Stuyvesant huskily. Then he left Cecilia with many maidens and singled out John. "If you don't mind, I'm going home now," he said. "I'm tired. Thank you for bringing me along."

He looked back toward Cecilia. He saw the top of her golden head, surrounded by others of more elaborate coiffure. They made a worshipping circle around her.

"Gosh!" said K. Stuyvesant. He recalled the little second when he'd drawn her nearer. "I'm not sorry!" he thought, then turned to hurry away from the lights and the music, for he wanted to be alone.

CHAPTER XV

FIRELIGHT

"It's a serious," said a boy with a voice like a nutmeg grater.

"Yuh boob!" exploded his companion. "He means a serial," he explained to Father McGowan.

"And," said Father McGowan, "you have come to me because you are temporarily embarrassed for funds?"

"Yep," said the nutmeg grater. "We're broke."

"An' it's that exciting! Every time they busts up an automobile an' wrecks a train--we'd pay yuh back,--an' him an' her in it, they----" broke in the other.

"You'd like a loan," said Father McGowan. "Well, well, here it is. What's the name of it?"

"'The Iron Claw,'" said the younger impressively. "It's grand. Them there shows learn yuh a lot too." His voice showed his great thirst for knowledge. Father McGowan smiled. He was urged to go along, with the assurance that they would also pay for that in the future, but he refused on the plea of work.

He went to the rectory door with them and let them out into the dismal snowfall, the first of the season. Half-hearted, damp, then he went back to his study, with a tender look in his eyes.

He was thinking of a small boy who had known no such pleasures--a small boy brought up by an always-old aunt, whose heart and soul were cut square, and without any dimples. He had been a very quiet small boy with a great hankering for nails and something to pound with.

He had gone through the pound period without pounding, and when he reached the dream time he knew that dreams to his unyielding old aunt would be as troublesome as nails, so he had kept silent.

Father McGowan's eyes still held the wistful look that had come into them at seventeen. He recalled all his naillessness as he saw two joyful theatregoers start off to see "The Iron Claw," but in thinking of it there was no regret--only a gratitude that from his denials had come a backyard full of junk and a paradise for many little boys who otherwise would have gone without their small-boy heaven.

"She was a good woman!" said Father McGowan; "a good woman!" He was thinking of the still old aunt who'd brought him up.

"Are you well, Father McGowan-dear?" asked Cecilia later in the afternoon when Father McGowan had settled before a fire in the Madden library.

"Oh, yes," answered Father McGowan. "Have a little cold, but I feel splendidly." Cecilia did not look impressed, and certainly Father McGowan's aspect was not convincing. His head was thrown back against the chair, and his breath came raspingly.

"A hot lemonade," said Cecilia rather to herself.

"Never!" said Father McGowan. "Never! Cecilia, you are a dear child. Don't irritate me. I hate lemonades. They make me think of money for the parish house, and they are bad enough cold."

"Hot toddy?" suggested Cecilia; her eyes twinkled.

"Ah--!" replied Father McGowan softly. Cecilia rang, spoke to a haughty person in buttons, and soon Father McGowan was sipping something warm which did not smell of lemons.

"How's the pain?" asked Father McGowan in a commonplace tone; he studied the glass he held.

"Oh," answered Cecilia, "it is the same, but I am braver. I _will_ be good, Father McGowan. I can't help lov--caring for him. I fixed my hair eight times the other day when I knew I'd see him, and used an eyebrow pencil Marjory left, but it wasn't becoming, and I washed it off. I can't help caring for him, although I know he's unworthy. I seem to have lost my handkerchief,--thank you." Father McGowan supplied a large square.

"You didn't use to cry much, did you, dear child?" he asked gently.

"No," answered Cecilia, "and I don't now except with you. You see, when I voice it it becomes so tragically real. It is fixed because I speak it to a human, while when I think of it it seems like a bad dream. It--it doesn't seem possible that I can care so much, while he doesn't."

The fat priest reached for Cecilia's hand. He lifted it and kissed it. Cecilia looked surprised.

"A token of immense respect and humble love, dear child," said Father McGowan. "Kisses," he continued, "Cecilia, tie to the man who humbly kisses your hand. There are two kinds, the kind who wants only your lips and the kind who humbly touches your hand and who longs to be absolved by whimpering out his shames against your throat. Lord, what an old fool I am! _What_ a subject for a priest to lecture on!"

Cecilia was silent, for she was thinking of Stuyvesant's kisses, which still burned her palm. They had held humbleness,--and hunger. She remembered how he had muttered that he "darn well wanted to get down on his knees, gosh! How he _did_ love----" And then Mrs. Higgenmeyer had come along and called loudly of the night: "Purty night, ain't it?" and, worse, the chaperone of Boston had then appeared and said in her crisp, quick-cut way: "'Beautiful night of stars,' as our inimitable Mr. Browning said."

Then the man with the Vandyke beard from Philadelphia had passed. He had crossed forty times, had a valet, and complained of the coffee and service, therefore commanding every one's respect. "Stevenson," he had corrected in passing. "Horrid person!" said Miss Hutchinson, but to Cecilia there were no horrid persons, for the world was full of a tall, gruff man, and her heart was swollen from his hot kisses on her small palm. Her eyes must have told him something of this, for he muttered, "Dear!" with the impetuosity of a loosened champagne cork. "What say?" Miss Hutchinson had asked.

"Father McGowan," said Cecilia, "shall I ever be allowed to forget my inferiority to the most? It is always there, even when they ask me for money for their charities. They say, 'Mrs. Dash has subscribed. _You_ will probably _want_ to.' By right of bricks, I purchase my admission. Shall I always feel this way?"

"Oh, no," answered Father McGowan. "When you get past thirty you forget how you feel--that is, if you're any good. After that you think of others, and the _ego_ is rubbed down by the world into its proper size."

"I _am_ a pig!" said Cecilia.

"You're not!" disagreed Father McGowan. "No one could call you that----" He paused. "For a long time," he went on, "I've wanted to say something to you, because you are too near it to get a perspective. I want you to look around at the snobs who do not mix with those in trade, and then I want you to ask what grandpapa did. Probably he made pretzels or ran a laundry. Do not ask the

immediate members of the family of this, for they may not like it, but ask some _kind_ friend. You and John, you people of stronger, fresher blood, are America. You are what comes in and puts bright eyes into depleted stock and takes out the hiccoughs. Don't apologise for your strength and the fact that papa's reservations for his first trip were made in the steerage."

"I don't," answered Cecilia. "I'm rather blatantly proud of it, although since boarding school I haven't bragged of it."

"In time you may even elevate your lorgnette and ask coldly, 'Who _is_ she?'" suggested Father McGowan.

"Oh, no!" said Cecilia, "I'll _never_ do that!"

"Your children probably will!" said Father McGowan, and then he said "Drat!" to his own stupid self.

"My children," said Cecilia, "are gentle, white ghosts, and they play and do only what I dream. They would never do that, I would send them from my arms first, and I do--love them. My arms would be empty. Am I going to be a sentimental old maid, Father McGowan-dear?"

Father McGowan said he thought not. Then he turned and again quite brazenly kissed Cecilia's small palm.

"Cecilia," he said, "to-day seems like the end of the world to me.... My soul is on wings. Dear child, I wish you could know what you have always been to me. But you do, don't you?"

"Yes, Father McGowan-dear," answered Cecilia. "I have known. I have always brought my worst hurts to you, and one does that only to one who loves."

"Well, well," said Father McGowan, unused to personal sentiment and awkward from it, "now we understand. How's John?"

"Wonderful," answered Cecilia. She smiled mischievously. "Almost a boy again," she added in explanation.

"Twombly responsible?" asked Father McGowan.

"Yes," she answered, "entirely. His ideals when transplanted are unusually good. However, they do not seem to take root in him."

"Well, well," said Father McGowan. He stretched in a tired way and said he must go. No, he couldn't stay for dinner, for he was to take the night turn at nursing a burned iron moulder. "Won't he be thirsty when he sniffs my lemonade?" said Father McGowan.

Cecilia rang; the lofty person appeared. "Just a minute," said Father McGowan. "I want one more word with you." The person faded.

"Cecilia," said Father McGowan, "there's a doctor to whom your father is playing God. I don't want to bother you about it, but to-day, coming here, I somehow felt as if I ought to." Father McGowan settled on the edge of a chair, and he told Cecilia the dry facts of the ruin of Doctor Van Dorn. "Try to make your father see that it's better not to tamper with the works," he ended; "to leave that to whoever or whatever is pushing the old ball around.... Well, good-bye, dear child. Oh, I can get out without the help of his Royal Buttons, thank you."

After he left Cecilia again settled in front of the fire to think of her new problem. Her brain eluded it with a maddening persistency. She thought of a new frock, the Girls' Club, a dance. Then again of the really horrible revelation, and the unexpected obstinacy of her father.

She looked up at a softly coloured painting above the mantel, which she'd had painted in Paris. It had been marvellously done, and especially since the only model had been a small tintype.

"Dearest," said Cecilia, "you would not want him punished, would you? And,--is there any punishment more cruel than life?"

The painting smiled down gently.

"Pink roses," it seemed to say. "There are always pink roses, but youth must hold them to see their beauty.... Seeing no loveliness in dreams denied, no heights in greatest depths...."

"Come in!" said John. "Please!" K. Stuyvesant hesitated. He wanted to, for just a glimpse of Cecilia was everything to him; but, she--she had not wanted to see him. "I am out a great deal," she said in that memorable 'phone message,--also, "I have quite forgotten the little episode of the boat." Those two sentences had made things cruelly plain.

"Come on," begged John, "you must be cold!"

K. Stuyvesant got out of his machine, and went with John into the long-waisted house.

"Fire in the library," said John; "wood, you know. Bully, aren't they?" John, ahead, stopped with his hand on the drapery which softened the broad doorway into the library. He put the other, silencingly, on K. Stuyvesant's arm. Cecilia sat in front of the fire. She held a framed picture in her hands, standing upright on her knees. Looking,--looking,--looking, she was. They stood there for what seemed to Stuyvesant many minutes. He felt himself grow hot, cold, then he longed to shake John,--again, hug him.

"Celie!" called John. With a crash the photograph slipped from her hands to the floor.

"Oh!" she cried breathlessly, "_how_ you frightened me!"

"Come in, Stuyv," said John, loudly. "Look what she's looking at! _Your_ picture!" Stuyvesant didn't answer. He had set his teeth, and his chin was very square.

"How long were you there?" asked Cecilia.

"We just came in," said Stuyvesant, before John could answer.

"I just picked up your picture," said Cecilia. "John hadn't shown it to me. I'm sorry I was stupid and broke the glass."

She moved, and Stuyvesant's eyes followed her, a heartache too large for concealment showing in them.

"Whatcha go for?" asked John. "Stay and talk!"

"I really can't, dear," she answered. "I'm sorry." Then, nodding, she disappeared. In a moment they heard the sound of the piano. Some one who could feel, as well as play, was tinkling out "The Shepherd Boy."

"She does it for dad," said John, "because he likes it, but you ought to hear her play good music. She's a wonder; why, in school----"

John broke off, another thought interrupting: "Why didn't you let me jolly her about your picture?" he asked. "It was a great chance."

"She wouldn't like it," answered K. Stuyvesant miserably. "Please don't tell her we were watching her, will you, John?"

"Aw,--why not!"

"_Please_, John!" Stuyvesant's voice was earnest.

"Well, I won't," agreed John in a disappointed way. "But I do like to tease her! She's awfully cunning when she gets excited, and you can get a rise out of her every time."

After that they settled to play rum for a small stake. Stuyvesant was absent. Time and again John and the cards faded while he saw Cecilia sitting before an open fire,--soft in the firelight, gentle,--almost ready to smile on him. His picture? ... Probably scorning him,--but,--at least she'd thought of him for that little space. He looked toward the chair, and he saw her gently smile in his direction.

"Rum!" yelled John, much delighted. "That puts me out. Gee, you're in the clouds! You owe me forty-nine cents."

CHAPTER XVI

THE MYSTERY

The rectory hall was quiet, although it was well filled with people--shabby, the most of them, and sitting uneasily upright in their chairs. Damp snow clung to the coat of one woman who had just entered, and the smell of dirty and wet clothing was in the air.

Now and again the steam pounded in a low radiator below a window. There was a great deal of sniffing, and a hacking cough from a woman who bragged of a "weak chest." At last an old man who had been fingering the brim of his hat spoke in a hoarse whisper. "How _is_ he?" he croaked. His thumb pointed over his shoulder toward the stairs.

"Ain't no better," responded the woman who coughed. "_She_ come down a half hour ago an' sez 'He's the same.'" The woman coughed again, and afterward wiped her eyes.

"He gimme a pipe," said the old man, turning the hat in his hands. "It hez a real amber mouthpiece on. He sez, 'Here, Jake, you know a good pipe, now I don't. This here was gave to me, I want you should hev it,' he sez,--like that he sez----"

"I bet!" said a frightened looking little man, hitherto silent, "I bet he did! What he done fer me----!" The little man stopped, looked around, and cowered back in is chair, swallowed several times, then spoke in a high voice, evidently unnatural and the fruit of great effort. "I was in the penitentiary," he said, "an' when I come out no one would gimme a job. I was despert. I got my wife, an' her aunt, what's had a stroke, an' can't use her limbs no way. My wife took to coughin' an' couldn't work no more. Gawd, it was fierce! I was despert. I come to him. What he done fer me----! I sez 'What kin I do? I gotta feed them women. Hev I gotta steal again?' He sez no, an' he set me down an' gimme a meal. Talkin' to me while I et ... Gawd, I never kin fergit it.... That there meal was none of them cold potato hand-outs served up with a sneer. Human beings is awful rough with each other sometimes. When I got through I got up. I sez, 'I don't want no more. I guess I kin hunt my own job now, fer you've made me a man agin....' He sez, 'Well, well,' an' then he set me down, an' believe it or not, he gimme a c_ee_gar! A fie' center too! Then he come with me to my old woman, and Aunt Ellen, an' he seen that they was did for, an' the next week he got me a job at the cement plant." After he finished he cowered again. The world had shown him little forgiveness. His world was scorn, or a hidden shame.

The little man had, in telling of Father McGowan's goodness, voiced his crucifixion. The pain of telling it made him feel as if he were at last thanking the big priest adequately.... He blinked, and avoided his companions' eyes now. He knew what to expect.

"I'm glad he helped yuh," said the old man, "but he would. There ain't nothing he wouldn't do fer nobody."

Common sorrow, like common joy, had drawn these people together. The love of the man upstairs had filled their souls, and left no room for littleness. The little man of the penitentiary was one of them, not an outcast.

He sat up straight again, still blinking. "Yer right," he said; "he's helped a lot of us to believe there is a Gawd ... an' something beside hell, livin' or dead."

"Yep," answered the woman with the cough. She drew a shawl close about her and moved near the clanking radiator. "Ain't it cold?" she said. "I'm used to settin' near the stove. I wisht she'd come. That there woman in white, I mean, the one what nurses him."

"I wish too," said a fat soul who surveyed every one with suspicion. "I gotta get home an' pack my man's dinner pail. Night work he does. It ain't so nice. _I_ don't get no company. All day long he snores, an' at night I set home, or go alone. We used to go to pictures every Monday regular as clockwork."

"He helped me buy a parlour organ," said a thin woman a little apart from the group. "I come to him, and I sez, 'I'd go hungry to get a organ, what I could pick out tunes on, an' mebbe learn to play "Home, Sweet Home" on.' He sez, 'Well, well!' (yuh know his way) an' then I told him how I'd wanted one, an' saved up, and then had to use that there money to bury pop (his insurance havin' ran out) an' he helped me. I got it. I kin play three measures a 'Home, Sweet Home,' real good, except fer being slow in the bass.... There ain't nothing like music fer company. I don't get lonely no more of evenings. I use to get that down, an' tired a settin' alone after work, that I'd hate to hear the six a'clock whistles. It ain't no joke, settin' in one room with the wall paper all off. I wonder how he is?" she ended in another voice. No one answered. The woman near the radiator coughed, then wiped her eyes. The old man twirled his hat.

A girl with a sullen look slunk in, and settled near the door. There was quiet. Once in a while a chair was moved, and grated on the floor. The radiator clanked. There was the staccato tap of heels in the upper hall, then on the stairs.

"_You_ ask her," said one woman to another.

The old man spoke. "Mrs.," he said, "how _is_ he?"

"There ain't no change," said Mrs. Fry, "and there ain't no sense to your settin' here."

"We'll be quiet," said the old man wistfully, "and we'd kinda like to. We all love him."

Mrs. Fry covered her face with her handkerchief. "Set if yuh want to," she said in what was, for her, a softened tone, "but there ain't a bit a sense to it." Then she turned and went down the hall, blowing her nose loudly.

"There's three doctors," said a girl just out of childhood, and yet from her place in life old looking.

"I know that," replied the thin woman. "It looks bad fer him, but he _can't_ die! There ain't another!"

"He won't die!" said the old man. "Fer them that knowed him, he'll always live."

In the kitchen Mrs. Fry was sobbing in the roller towel. She heard Father McGowan's voice come, as it had, in gasps. "Now,--now! Mrs. Fry----" echoed in her heart, "don't feel badly--I'm tired,--and--I'm ready to go--to sleep----" And then he had smiled.

"Mrs. Fry," came in a voice from the doorway, "yer wanted!" She looked up to see an old man with the tears running down his face and following the wrinkles in criss-cross paths of salty moisture.

The nurse stood in the hall. She alone was calm. "You'd better go now," she said quietly to the little group. Several of them sobbed loudly. The door opened suddenly. "Where's Father McGowan?" called a little boy. "I got a new kitty what I want to show him. _Ain't_ he in?"

Cecilia was on her knees in the dark, by her bed.

"Father McGowan," she whispered, "oh, Father McGowan-_dear_, where are you?" He had not gone where childhood had had an Irish mother go. Growing had made the mystery--the vast uncertainty--the haunting question of the still, dark hours!

Cecilia lifted her face. Her eyes were dry. "Oh, God," she said aloud, "if you are, give us another life. There is no possible good-bye for little human hearts that love. Oh, God, let me see Father McGowan-dear again. Oh, let me! I will be good all my life, if I may meet him once again----"

She stopped, choked.

The mystery echoed.... "Father McGowan-dear," she whispered, "where _are_ you? Dearest, _where_ have you gone, and why?"

CHAPTER XVII

A RELAPSE

"He died," said Johnny, "of pneumonia. One of those quick cases, you know. Cecilia's frightfully broken up--you can see it--although she doesn't say anything."

"I'm sorry," said Stuyvesant.

"I never saw much in him," said John musingly, "but he had an awful hold on a lot of people."

"Your sister cared for him, didn't she?" asked Stuyvesant, then added bravely, "I think that assures his being unusual."

"Oh, I don't know," said John in a lazy way; "girls are queer,--sometimes sentimental. He was good to her when she was tiny. She always remembers things like that. I think she's kinda sentimental."

Stuyvesant looked peculiar and grunted.

"Saw Tommy Dixon down town to-day," said John. A sudden flush spread across Stuyvesant's face. His eyes were unpleasantly bitter. "Good sport," continued John.

"I disagree," said Stuyvesant loudly. "Don't like him, nor his rotten code." John looked on Stuyvesant speculatively. He reflected that, after all, Stuyv didn't know it all, and that if he wore a cassock he might have been taken for Father McGowan. His ideals were very similar.

"Can't train with a Sunday school class," said John. "Live while you're here, yuh know. Damned if I haven't been good lately!"

Stuyvesant was worried. Thus far his work had been easy, because of John's adoring following. But,--were John to follow Tommy Dixon with the same adoration,--then,--it _would_ be work! He thought, with an inward sneer, of the smallness of the boy's measures for life. He thought of his always following the new, and of his weak swaying, and then he thought of who had asked his help.

"Come to dinner with me, John," he said, while he made mental arrangement for the cancelling of another engagement.

"Don't mind," answered the old John, in his old tired-of-life manner. "Got a date before dinner. Where'll I meet you?" Stuyvesant named a club, and they parted. Stuyvesant went to his office. There were several matters awaiting his attention, but he pushed them aside. Across the room he saw Tommy Dixon's insolent face. On it was the ever-present smile, that which shaded into a leer too easily.... "She says she can't forget his kisses," came with a touch of flame across his tortured brain.

"God!" said K. Stuyvesant. "God!" He hid his eyes with his hands. His breath came fast.

It was half after eight, and John was to have met him at eight. Stuyvesant looked at his watch, and frowned. The day had been hard, and had left small capacity for patience.... The mention of Tommy Dixon had brought back a misery he'd hoped somewhat dulled (one remembered by a stern control of thought, usually not more than once a day).

Now John, after Stuyvesant's breaking an engagement,--was late. His casual acceptance of Stuyvesant's hospitality brought a smile to that gentleman's lips. He wondered if John thought he courted the opportunity of hearing his rather young, and too often callow, opinions stated with absolute assurance as truths?

At nine Stuyvesant shut his watch with a snap, and went out alone to dinner. He was entirely out of humour. He allowed himself to meditate largely on Tommy Dixon. It was torture--exactly fitted his mood, and helped.

"Celie," said Jeremiah.

Celie stopped playing the chimes of a new "piece" of Jeremiah's pattern.

"Celie," he went on, "I done that you asked."

"Doctor Van Dorn?" she asked in a whisper.

"Yes," answered Jeremiah. He blew his nose loudly. "_He_ asked me, an' he asked me," Jeremiah explained, "an' I was that uppish! Jeremiah,' he'd say, 'don't try to cast yourself for God. It won't work,' an' I'd say, 'Is it going to rain, Father McGowan?' Just the last time he come I seen him in the hall, an' he was pleadin' with me; he sez, 'You can control his work. See that he does no harm, but don't do more,' an' I sez, 'It's snowin' now, ain't it?' Oh, dear Lordy! Ain't life one mess of regrets! One after the other, spoilin' your digestion, an' makin' yuh kick around of nights! ... I loved him too."

"Dear," said Cecilia, "he knew that!"

"Yuh think so, Celie?" asked Jeremiah wistfully. "Oh, yes!" she answered. Her answer held an applied genuineness. It convinced Jeremiah.

"I give him back his rotten little factory (I was losin' money on it, anyway), and I wrote him a letter. I sez, 'Dear Sir----' An' I went on telling him Father McGowan an' Gawd done it, not me. I sez I was his well-wisher now, wishin' him all success, an' I sez not to get funny in the hospital business on sick kids no more or I'd have him jailed. The letter was friendly and Christian, all owing to Father McGowan, who doesn't know it--God rest his soul!"

Cecilia was smiling tremulously. "You absolute darling!" she said. She perched on the arm of his chair, and they sat in silence.

"After all," she said, "hurting this little man wouldn't bring mamma her pink roses, would it, dear?"

Jeremiah's eyes snapped. In them was the look that certain competitors, who scorned him socially, dreaded. "It brung me mine," he stated; "it brung me mine!" Cecilia laughed. A sudden lightness of spirit, like the flash of day into dawn, was hers.

"Dear," she said, "I believe Father McGowan knows! I believe he does!" Jeremiah kissed her and smoothed her golden hair with his hand which would never become smooth. "You're like your maw," he said. It was his greatest tribute. Cecilia clung to him with a pathetic hunger.

"Miss Cecilia, the telephone," said the pompous person from the doorway.

"Yes, sir; yes, sir," answered Jeremiah, "she's a-coming." Cecilia went to an adjoining room. After her "yes" things swayed a bit. She did not need his voice, which said, "This is Stuyvesant Twombly." She knew. "Yes," she repeated.

"I _have_ to bother you," he said. "I've just had a message from John. He's been a little hurt--just a little, Miss Cecilia, and he wants you to come with me to where he is. He's a little hurt. You won't worry? I'll stop for you in a moment, that is, if you'll come?"

"Oh, of course!" she answered; "but you're sure he's not really hurt?"

"Yes," he answered. "Do up well. It's cold." She hung up the receiver, and stood a minute, hand over her thudding heart. She was not thinking of John.

As for Stuyvesant, he hung up the receiver and swore loudly. He was thinking of the 'phone message which had come from John, and of John's small sister. "Stuyv," he had heard John say, "I'm up here at the Eagles' View House. I had a bust-up. Get Celie and come. I'm dying----" There had been a lull. "He's fainted," had come across the wires in another tone. Stuyvesant's first amusement over the last 'phone message faded suddenly. Perhaps John had made the supreme effort and had managed to speak those few words? Then he abandoned speculation and telephoned Cecilia. He had assured her that John was not much hurt.... The gentle care of her was instinctive. If John were right the other would come later.

With a doctor in the car they drew up before the Madden House. The chauffeur was not off his seat before Stuyvesant was out and on the steps. "Are you warmly enough dressed?" he asked of her.

"Yes, thank you. John?" she questioned.

"He telephoned me that he had a smash-up and that he wanted you. I have a doctor; he may have some sprains or bruises," said Stuyvesant.

"It's so good of you," she responded. All of Marjory's hints had gone. She felt his hand on her arm and felt from it a sweet sickness.

"Miss Cecilia, may I introduce Doctor Holt? Miss Madden----" After that she settled, and felt rugs being wrapped around her. Stuyvesant's hands lingered. They held a thrilling tenderness. "Are they well around you?" he asked. Cecilia said they were, and Stuyvesant drew a long breath. The doctor looked from one to the other speculatively. He judged them lovers and himself in the way. The girl was certainly entirely lovely--the soft type who asked for gentleness in return for unbounded love. The way she looked at young Twombly as he stared straight ahead was rather beautiful, thought the doctor. She jumped as he spoke. "These gay young men and their speeding," he had said.

"Oh, yes," said Cecilia, "aren't they fearful? I think they should be reared without silly sisters to worry over them!"

The doctor agreed. He imagined young Madden to be a hard-muscled fellow who liked sport. In speaking of speed, his only thought had been mileage.

The car had left the city and was running with difficulty over a road which was bad from a light snow.

"Miss Madden is skidding quite a bit (pardon me, Miss Madden) alone on that back seat. You'd better get back there, Mr. Twombly," said the doctor. He smiled. He thought he had done something very kind, and done it neatly. Mr. Twombly stuttered something that sounded like, "I'm glad; I'd be glad--pleased----" Cecilia stared agonizedly ahead. The car made a turn, and, alone on the broad seat, she swayed, slid half across the seat, bumped.

Stuyvesant turned his chair. "May I, Miss Cecilia, or the doctor? We're going so fast. You'll be so jolted." In answer she turned back the rug, and Stuyvesant settled by her. After that there was quiet. Cecilia looked ahead, through steamed glass, at the ears of Stuyvesant's chauffeur. Stuyvesant sneakingly looked at her.

"Only ten," said the doctor; "we're making good time."

"Pardon?" said Stuyvesant, and at the same time from Cecilia, "Excuse me. I didn't hear." Under cover of the dark the doctor smiled. Cecilia flushed, and Stuyvesant bit his lip. He clasped his hands together very tightly, for he was afraid that if she looked toward him he would put his arms around her and draw her close.

The doctor began to criticise the administration, as people always do when they know little of the facts. Stuyvesant clutched the straw, and argued hotly first on one side, and then the other. The doctor was pleased, for K. Stuyvesant was illustrating a pet theory of his, universal insanity. "Now if Van Dorn could hear this!" he reflected. "Why, the man could be locked up! He's much worse than millions in asylums!"

The car jolted, and turned. Cecilia swayed, and bumped against Stuyvesant's arm. It slipped back of her protectingly, and closed around her. "That was a jolt--" he said shortly, "these roads,--did it jar you?"

"No," answered Cecilia, "thank you." His arm had been pulled away with a jerk. Cecilia stared ahead at the chauffeur's ears. They were large and floppy, and the whole world seemed like them, a misfit. She felt chilled, alone, afraid. She wished the car would jolt again. She wished so brazenly. She didn't care,--she did!

At the Eagles' View Cecilia was ushered up creaking stairs to a cheap, little room. It was shabby, and hung with soiled cretonnes. There were pictures on the walls, entitled "The Bathers,"--"Playful Kittens,"--"A Surprise!" Some more lurid with titles impossible. Stuyvesant had followed Cecilia and from the doorway, over her head, he caught the impression. He had expected it, but it hurt cruelly. His spirit was a mixture of longing to press her face against his shoulder, and a great hankering to kick John.

"I'm dying!" gasped John.

"My dearest!" said Cecilia, and caught her breath sharply, then she slipped to her knees by the bed. She put her arm beneath his head, which was too low, and turned to Stuyvesant. "Where is the doctor?" she asked. At that moment he appeared in the doorway. "Well, young man," he, said, "speeding?"

"I'm going to die," answered John in gasps. Cecilia had grown very white.

"Nonsense!" said the doctor. "Now if you people will just leave us for a few moments----" He began to open his case as he spoke.

"Want me?" asked Stuyvesant.

"No," he was answered; "you take care of Miss Madden." The door opened and a girl appeared. Her hair was streaked from bleach, and dark at the roots; her expression insolently daring.

"How yuh feel, honey boy?" she asked of John. John turned away his face. He looked sicker.

"One of your friends?" questioned Cecilia. John did not answer. "Yes," replied the girl. "I'm Miss LeMain. Me and John have been pals for this long while."

"I'm John's sister," said Cecilia, and held out her hand. Miss LeMain took it with a limp and high gesture cultivated as "elegant." "Pleased to meet yuh," she murmured, and then, "I'm glad you've came. My nerves is that shook up! Mebbe the gent'man would get us something to drink. My nerves is all shook. I feel fierce."

They descended the rickety stairs, the girls followed by Stuyvesant. If John had been well something would have happened to him. As it was Stuyvesant was fiercely protective of the small sister in a curt, silent way. His anger was almost overpowering.... He thought of Cecilia on her knees in that evil room. He thought of her gentle treatment of Miss LeMain.... He was humbled by her sweetness, and furious from its cause.

"Is he your gent'man friend?" asked Miss LeMain while Stuyvesant ordered the drink. Cecilia shook her head.

"Thought he was. Seems like a cute fellah. Gawd, my nerves is shook! Jacky speeds so! I sez, 'Jack, you'll do this trick once too often!' an' he sez, 'I'm running this boat, girlie,' an' I sez some more, an' then he kissed me; yuh know what a kidder he is! An' the car a-running like that! Then the next thing she was over, an' I was in a field. Jack was somewhere in the road. This ain't the _first_ accident I been in. I believe in a short life an' a merry one. All my gent'men friends has cars. No Fords neither. I hope Jacky ain't suffering. He's a sweet boy, an' some sport!" Cecilia's hands were locked tightly together in her lap. Her eyes were tragic. "My nerves is shook up fierce!" echoed Miss LeMain.

"I'm sorry," said Cecilia.

Stuyvesant had appeared in time to hear the last of the recital. "You'd better go lie down," he said decidedly. "It will do you good, and Miss Madden needs quiet."

"An' 'two's company, three's a crowd!' ain't that it?" questioned Miss LeMain with a giggle. Her sally was not greeted with enthusiasm. She left, terming Stuyvesant a grouch, and Cecilia sweet, but lacking pep.

Alone, Stuyvesant stood looking down at Cecilia. His arm was on the mantel. The shadows and lights from an open fireplace played on them. The rest of the room in half dark brought them close. Constraint was impossible because of the situation and Cecilia's dependence on Stuyvesant.

"The money came too quickly," she said meeting his eyes. "John has to spend it in the way that makes the most noise. I--I am so tired of it! So bruised by it! I wish we were back in that little flat, with John laying bricks as my father did. Perhaps then he would be a good man. That is everything to me."

"He is going to be a good man, Cecilia," said Stuyvesant. Neither noticed the use of her first name. "He will be a good man. This is a relapse,--a recurrence of growing pains. There are good things in him. When he's awake he has a sense of humour. That is a darn good thing to have, you know. I think, next to God, it's the best thing a man can own."

Cecilia pressed her handkerchief against her lips. "You will help him again?" she whispered.

"I will," said Stuyvesant. He put out his hand in pledge and hers was swallowed in his huge grasp. At the touch of her hand he gasped, "Cecilia!" but she did not answer, for the doctor's step was heard on the rickety stairs.

"Two broken ribs," he said; "scratch on his arm. Now we'll take him home. He'll probably yell over the bumps, but I judge the yells will do him good. Where's his companion? Send another car for her, or take her along?"

"Send for her," said Stuyvesant.

"No," disagreed Cecilia, "if you don't mind, we'll take her. I think it would be better." Stuyvesant looked annoyed, but sent the oily proprietor to call the lady of the shook-up-nerves. She descended immediately, wrapped in a large fur coat, and with a cerise motor scarf about her head. "I couldn't get no rest," she called; "I'm all fussy. How's Jacky darling?"

"_She_ isn't going with us?" said John at the top of the stairs. He stopped and leaned heavily on Stuyvesant. "My God!" he exploded. "Stuyv, she _can't_! Celie can't meet her! She can't! Tell her we'll send a car. I don't want Celie to see her."

"They've been talking for half an hour," said Stuyvesant. "Your sister insists on taking her in."

"Oh, Lord!" said John. "Oh, Lord!"

"Come along!" said Stuyvesant roughly.

"I really thought I was dying," said John in a shamed way.

"Shut up!" ordered Stuyvesant. "You make me sick!" They went down with no more conversation.

"How are you, dear?" asked Cecilia.

"Oh, Celie!" said John. He reached for her hand and clung to it. "Oh, Celie!" he echoed.

Until dawn Stuyvesant relived the night. The ride home had made the deepest impression. A girl with a painted soul and face had chattered loudly, and with a cheap sentiment reeking in her talk. She had spoken often of "Jacky darling."

While Jacky darling, from shame and pain, had groaned in deep, shaky groans, his head had lain on his sister's shoulder. On the other side Stuyvesant had sat. The doctor had disposed of the case as typical, and was thinking of an article which he'd just read in the _Medical Journal_.

"Dearie," Fanchette LeMain had said, "your fur's open." She had reached toward Cecilia's throat, but Stuyvesant reached first. He fastened the clasp with shaking hands, and the back of one hand touched her chin. Then he had sunk back to dream his impossible dreams, and wonder why she should have cared. He knew he was a duffer! But he was almost sure that she once had cared,--for him.

CHAPTER XVIII

FORGIVENESS

"Celie," said John, "honestly he was devilish to me, and I deserved it!" John was lying on a lounge, covered and looking wan. The library fire burned cheerfully, and the portrait of an Irish mother smiled down on Cecilia and John.

Stuyvesant Twombly had just left. He had uttered some scathing truths.

"He said I was a 'callow pup,'" said John. "He said I shouldn't have called you to that place if I'd been half dead. Cecilia dear, he was right. Celie, forgive me!"

"Dearest!" said Cecilia. She sank to her knees by the lounge, and pressed John's face to hers. He felt her tears.

"I never will again!" he said huskily. "God help me!" She didn't reply. She couldn't, but only pressed him closer.

"I can't bear to see you take the tawdry and cheap," she whispered at length, "for, John dear, it does crowd out the real. I know it does."

He nodded.

"Kiss me," he ordered. She turned her face, and then the door opened.

"I beg pardon," said Stuyvesant uncomfortably, "I thought you were alone." Cecilia had gotten to her feet, and stood, shy and flushing adorably.

"Cecilia's been weeping over the prodigal pup," explained John. "I told her I was sorry. I am. If you and she will give me another chance----" He held out his hand with his words, and Stuyvesant took it.

"I came back to say I was sorry I was so darn brutal," he said, squeezing John's hand, "but I'm afraid I meant it all."

Cecilia left them with a word or two. At the door she turned. Stuyvesant was looking after her, oblivious to John's presence.

"Celie's tears," said John, using a handkerchief on his cheeks. He recalled the new leaf, and added, "Three or four of mine too, I guess." His expression was sheepish, but that vanished, for in Stuyvesant's face was approval. "John," said Stuyvesant, "you're _all_ right!"

John coughed. The genuine gruffness of Stuyvesant unsettled him. "I'm awfully glad you came back," said John. "You'll stay? Let's play rum."

CHAPTER XIX

SPRING

"What are _you_ doing here?" Stuyvesant asked of Annette. Considerable surprise was in his face and voice.

"Oh," answered Annette, "I have been telling Cecilia Madden that I was a pig. I asked her to forgive me. I feel much better!"

They had met on the long drive that ran on the inland side of the Sound house, toward the main road.

"I'm stopping at a house up the road for Sunday," explained Annette. "Cecilia wanted to motor me back, but I needed air. Indigestion and conscience are so much alike. You want to breathe deeply after the easing of both."

"Yes," agreed K. Stuyvesant absently. "How could you ever dislike her, Annette?"

"She came into school," said Annette, "the rawest little person you ever saw. I felt the injustice of her having money, while I, who knew so well how to use it, had to scrimp and save. I saw her with everything in the world that would have put me into heaven and she was miserably unhappy. It was my first taste of injustice. I hated it. I never was a resigned person, you know, Stuyv."

"How did the girls treat her?" asked Stuyvesant. He was becoming gruff.

"We put her through a refined form of hell," answered Annette, "the cruelties of which were only possible for the feminine mind to evolve. Stuyv, _do_ look what you're doing! The gardener will be grateful to you!"

Stuyvesant had been switching a cane viciously. He had taken off many heads of a particularly dressed-up variety of tulip.

"I'll be darned!" he said, looking at them with surprise. "Couldn't you see how dear and all that kind of thing she was?" he queried farther. "I don't see how even a set of simpering, half-witted, idiotic, jealous girls could _help_ seeing----"

"So you're in love with her?" interrupted Annette.

Stuyvesant looked on his cousin with surprise. Then he answered. "Of course," he said, "but how'd you know?"

Annette laughed. After her laughter she slipped a hand through his arm. "Stuyvesant," she said, "your soul and mine are cut from a different pattern. It was always hard for me to understand you, but something has happened lately which has made me larger, much decenter. Stuyvesant, I want a long talk--a heart-to-heart effect. Will you walk back with me?"

"Of course," he answered.

"You'll be glad to know," she went on, "that after Cecilia had pneumonia she was quite the idol of the school. There was one of those complete shifts so characteristic of our American youth, and every one liked her but me. She used to try to make me like her with the most transparent little appeals. Heavens, I was a devil! She sent me violets at one time when I had a cold, and I gave them to the maid, and then spoke loudly before her of unwelcome attentions and social climbers."

Stuyvesant was walking in jerks. His arm beneath Annette's was rigid.

"She's forgiven me," said Annette, smiling.

He relaxed. "I am a darn fool!" he said, "but honestly----!" He stopped and shook his head.

"Doesn't she care for you?" asked Annette; "turned you down?"

"I haven't asked her. She's shown very plainly what she thinks of me."

"Rubbish!" said Annette shortly. "No man in love is a judge of anything! He only knows that she has blue eyes, or he can't just remember, maybe they're brown, but anyway they're beautiful!" Annette's cousin grinned sheepishly.

"What colour are they?" asked Annette.

"I don't know, but I guess they're brown. I know they're unusual, now aren't they, Annette?"

Annette giggled. "Very ordinary," she answered, "and they happen to be blue."

"They're not ordinary. You know they aren't! It doesn't make any difference to me, of course. I'm not in love with her looks, but they're _not_ ordinary!"

"It is not like you," said the girl, "to give up anything you want in that half-hearted way. I don't quite understand, Stuyvesant."

"I----" he began, then stopped.

"Well?" questioned Annette.

"I didn't give it up without being sure. Her friend Marjory, well, she made me see a few things." He was staring moodily ahead. A car whizzed by, leaving a trail of dust. "Damn!" said Stuyvesant. Annette laughed. "You see now if I asked her," he continued, "I'd lose my chance of seeing her. I don't suppose you or any one else could know what that means to me!"

"You might not lose it. I don't trust the green-eyed lady. I never have."

"But she's Cecilia's best friend," objected Stuyvesant, "and why would she do anything to hurt her?"

"I used to think you posed," she answered despairingly. "Now I imagine it is only feeble-mindedness. Take my advice, Stuyvesant: _Ask_ her! The other course is so spineless."

"You don't know what I'd lose!"

"You wouldn't lose it!"

"I wouldn't?" he repeated. "Excuse me, Annette, but really you don't know what you're talking about. I do. I know too well." His voice had become bitter. She looked at him and saw that in the year past he had changed greatly.

"And now about you?" he said in a changed way. "Are you still set on this working business? I hope you aren't. I honestly want to help. It worries me like thunder!"

"You're a dear!" responded Annette, "and that is quite a tale. Can't we sit on this wall? Whose is it? ... The Maddens own all this? Heavens!"

She perched on the wall and he lit a cigarette. "No, not now," she answered as he held out the case. "The small Saint Cecilia doesn't, does she? Well, she couldn't. She might revert to the cob pipe." It was a flash of the old Annette. Stuyvesant looked unpleasant.

"My tale--" said Annette. "You know mamma is a worshipper of the long-haired. Any one who can create _anything_--futurist painters, pianists, the inventor of a new cocktail. You know her, Stuyv."

"Yes," admitted Stuyvesant.

"Well, what with their bleeding and papa's insane investments, he never provided properly for us, Stuyv. Mamma used to go to him and really cry! It was pathetic! And all he would say was that he had no money."

"He hadn't," answered Annette's cousin.

"I'd expect you to sympathise," she said. "You men always do, but that isn't my story. When he died his affairs were in such fearful shape that mamma and I were terribly pinched. She never liked you, Stuyv, or she might have asked your advice. As it was, she invested in lovely nut groves in southern California. The promoters quite misrepresented them; they didn't pay at all or declare dividends or whatever they do. In fact they assessed the owners of the common stock for irrigation or something like that. I don't just understand business. About that time I met Dicky Fanshawe, who doesn't do anything original--only works--fearfully poor. I fell in love with him, but mamma saw me as the mistress of some gilt and pink salon, with a long-haired genius as a husband, and was simply devilish about Dicky. You know her, Stuyv."

"Yes," answered Stuyvesant. "I do."

"Then you know the Altshine failure took us in too."

"Yes," he answered. "I know. Why were you so stiff-necked about my help, Annette? I have enough to help you all you need, and I want to. You know it."

"Mamma has never liked you," said Annette, "but when the crash came, well, she was willing to live on you. For the same reason I was not. I know you disapprove of me. My ideals are not many, but under the circumstances----!"

"You make me feel an awful dub!" said Stuyvesant. "I haven't any right to disapprove of you or be lofty."

"But you do. Well, mamma saw me retrieving the family fortune in some romantic and bohemian manner. I was to create something, a book, or be a decorator for the smart, a reader of East Indian poems. She had splendid ideas, but the fact is, I've found, you have to have a hint of something inside to do anything successfully outside. I hadn't it.

"I descended to a social secretary and chaperoning that horrid woman's nasty little white pups, and from that mamma has consented to my marrying Dicky. He only has ten thousand a year, and I'm going to marry him on that! I love him terribly! Isn't it splendidly romantic?"

"Um," grunted Stuyvesant. "Annette," he said, "I want you to let me provide for your mother. You will? ... No, don't thank me. It irritates me. Oh, please!" After his last plea she stopped her effusive thanks and pressed his arm. Suddenly she laughed.

"What are you laughing at?" asked Stuyvesant.

"Cecilia advocated pink for the poor," Annette explained, "and I never understood how they felt until my terrible employer asked me not to wear frills. She said they weren't suitable for my position! It's all so relative, isn't it? Cecilia saw the panorama. I saw only my corner."

Annette slipped from the wall. "Must go," she said. "Dicky's coming out at eight. You want me to be happy?"

"Of course," said Stuyvesant. Annette's face changed. "Stuyv," she said, "it's everything when you find the one who fits your heart and mind.... _Ask_ her. Please, Stuyv. I can't believe she doesn't care."

"You're awfully good," he answered huskily. "Lord, Annette! If you were right----!"

Annette stepped near him. For the first time since the nursery days she kissed him. "Stay here," she ordered, "and think it out. Bye!" With a wave she left. At the first turn in the road she looked back. Her cousin was still sitting on the wall, and he was staring intently at the cigarette between his fingers. Annette had seen that it had gone out before she started.

"Poor boy!" she said. "Poor boy!" and then she thought of Dicky, who had turned her hard little heart softer to all the world. She forgot the "poor boy" who sat alone on the wall. She forgot money and things, the two which had mattered most to her, and once had been her life. With a new look on her face, she dreamed of a future--a future at which she once would have laughed.

Hers was the spirit that puts glory into the face of the tired mother in the overcrowded flat; beauty into the face of the tawdry little girl who sits on a park bench with her "gentleman friend"; youth into age, waiting for soft and endless night; a little touch of God, a hint of something larger, veiled for eyes too young; the proof intangible, sublime.

CHAPTER XX

PULLING OFF THE THORNS

The heat of June in the city drew forth a hot, damp steam. It made white faces and brought to mind sunstrokes, not June's country thought--roses.

"Gee, it's hot!" said John. He sat opposite Stuyvesant Twombly in a restaurant famed for its coolness. "Come out with me to-night!" he added. "Dad and Celie will be glad to have you, too. Come on! Awful nice and cool out there."

Stuyvesant answered absently, and smiled a little as he did. The idea of "Celie's" being glad to see him amused, even while it hurt, him desperately. He thought with a cankered humour of his trying to find out whether there was a spark of hope for him, after the talk with Annette had made his dreams too daring, and had made him need, all over again, proof of how little he mattered. He had gotten the proof. His first talk had been full of Marjory,--Marjory,--Marjory. He had not wanted to talk of Marjory. Again he had hated her for coming between them.

Cecilia had told of what Marjory's letters had held,--how dear Marjory was (Cecilia had been a bit breathless at this point)--how she, Cecilia, loved her,--where Marjory was,--where she was going. It had been a very surface talk, not once touching anything personal, at least no more than the small Cecilia's great love for her friend. Then John had appeared and Cecilia had excused herself with much relief and gone quickly away.

It was as always, her avoidance, and what in a less sweet nature would have shown as marked distaste. Stuyvesant had understood, and held on to his small privilege doggedly.

"Then I'll leave," Stuyvesant heard John say; he didn't know what had come before, "but I'll get home from school often and see you."

"I'm going away myself for a while," said Stuyvesant,--"I don't know just where. I'm tired of business,--everything. I guess I need a change." He thought miserably of the "change" he needed, and then shut his heart on her sweet image. He made up his mind to stop thinking of "that kind of thing," and his heart laughed at his decision.

[Illustration: CECILIA STOPPED AND GASPED. IT WAS HARDER THAN SHE HAD DREAMED]

"Stuyv!" said John aghast, "what am I going to do without you? Why, Stuyv! You can't go, at least for long. You don't mean a long trip?"

"'Fraid so," he was answered. "I guess I'd better, John. I--the fact is I've wanted something I can't have. I don't want to baby about it, only I'm,--well, I can't forget it here. I'm going to try a change. Damn it! What did I say that for? I hate to whine."

"Stuyv!" said John. He reached across the table, and squeezed the hand that was drawing designs on the tablecloth with a strawberry fork.

Stuyvesant felt the sympathy, and looked up. The boy on the other side of the table gasped.

"Is it as bad as that?" he asked. Stuyvesant shook his head, and then he uttered his own word and convincingly. "Gosh, John," he said, "it's the limit. I'd never have believed it possible."

"Would it help to tell?" asked John. Stuyvesant smiled a little. "Not exactly," he replied. "I did tell one person," he continued after a pause, "and after that it was worse. This person meant well too. Rot it, if I couldn't run a world better than it's run! I'd have people that love each----" he stopped, and looked wildly around. Then he mopped his forehead. "It's awful hot," he finished inanely.

"Yes," agreed John. "Lord, I'll miss you!" John was utterly despondent. "There's no one like you, Stuyv," he said in an embarrassed way. "You know how hard it is to say some things, but you can bet I know what you've done for me! I do--so does Cecilia. I had the wrong idea."

"I've been glad to be your friend," answered Stuyvesant. "You'll write me and tell me how,--how you all are?"

"Certainly," responded John. "Why, of course I will, but I don't know how I can say good-bye! Stuyv, I depend on you awfully. You know,--you know with dad, that is, I can't take his advice because I don't respect him."

"Why not?" broke in John's companion. "I'd like to know why not?"

John's mouth flew open. "His grammar----" he began.

"Trimmings," said K. Stuyvesant.

"Crudeness," said John.

"Companion of strength," said K. Stuyvesant.

"Mentioning money all the time," said John, "how much things cost."

"Better than spending it without mention on dubious objects." John looked away as Stuyvesant replied. "Look here," continued Stuyvesant, "you and I both know the honest goodness in your father--his rugged ideas of a decent life--his respect of them. The other things are tinsel balls on the Christmas tree. Desirable trimmings, but not essential for the tree's strength. A few more years will convince you,--absolutely convince you. Some day you won't even wince when your father forgets and uses his knife to eat from."

"Never," stated John.

"You prefer a man who is slippery both inside and out?" questioned Stuyvesant.

"They get along better with the world," said John.

"Oh, no," said Stuyvesant. "They get along better with the empties. A few people, those that count, look for something on the inside."

John suddenly leaned well across the table. "Look here, Stuyv," he said, "is this a bluff? Damned if I understand you! I was lying in the hammock on the porch last summer when Marjory and Cecilia came from the courts. They didn't see me, and I thought I'd hear about some beau and have a joke. I heard Marjory say that you said the old man should be kept in the garage. Not just those words, but smooth--Marjory's way. I never saw Celie so mad! She turned white as----"

"Did she say that?" shouted Stuyvesant.

"Lord, Stuyv!" said John, "everybody's lookin' at you. Yes, of course she said that. What's the matter with you?"

"What else did she say?" asked Stuyvesant. He was somewhat breathless, but for the sake of John more restrained.

"Well, Marjory told Cecilia what a hell of a case you had on her, talking about her eyes, and all that kind of stuff. Trust girls--they blab everything. Gimme the salt, will you?"

Stuyvesant shoved his glass of water toward John. "The salt, man!" said John, and then as he surveyed Stuyvesant with sad eyes, he added, "I hope it isn't catching."

"You go telephone her that we're coming out," said Stuyvesant.

"Who?"

"Your sister, of course. Tell her not to have any one else there. I've got to see her, John,--got to! Honestly, John, I've _got_ to. I've got to see her a little while alone. I really must."

"I think you've made it plain," replied John. "You say you must see Cecilia. You did mention that, didn't you?"

There was no room for anything but heaven in Stuyvesant. He nodded seriously. "Yes," lie answered, "I must! Really, I've got to, John!"

John howled. "The heat!" he explained, then he sobered.

"Look here, Stuyv," he said, "_did_ you say that?"

"What?" asked Stuyvesant, then he remembered, and for the first and last time made a certain utterance. "She lied," he said quietly, and then, "Oh, my _gosh_, I'm happy! I believe I'm going crazy."

"Oh, no!" replied John, "impossible."

"Yes, John?" said Cecilia.

"Stuyv's coming out with me," she heard him say.

"Yes, dear," she answered.

"Any one coming to dinner?"

"No, dear. Shall I ask one of the Welsh twins? They're always so sweet about coming."

"No," said John; "Stuyv and I were talking about dad, rather Marjory, and he's got a hunch that he's got to see you alone. Got to,--got to,--got to!" Cecilia did not understand, and was rather bewildered at John's laughter.

"Certainly he shall, John," she replied. Her heart beat in her voice. "Good-bye, dear," she ended, and heard the click of his receiver.

"Talking of Marjory" ... Cecilia turned away from the telephone and went to stand by the sea window of her room. She would help them both all she could. All she could.... She closed her eyes, for she felt sick and faint.

"How can I help him?" she questioned, for Marjory's letters had not held a mention of him, although Cecilia's had tactfully recorded his every move. She looked out on the world--it was grey like the frothing Sound.

"I will help them to be happy," she whispered unsteadily. "Father McGowan-dear,--I am learning. Some day I will learn to think of it, and smile----" Then she turned to dress.

Norah came in, and looked on happily. Cecilia was not vain after all. No, she didn't care which frock she put on, and she told Josephine not to fuss so over her hair, that it bored her. "What is the difference?" she had asked a little bitterly, and then to Norah she had said, "I didn't mean that! I didn't! What made me say it? I am not bitter, am I, Norah?"

"And why should you be," Norah had answered, "with everything in the world that money can buy?"

CHAPTER XXI

PINK ROSES

At five K. Stuyvesant and John started for the Sound house. The sun beat down cruelly with the same murky, hot-damp feel. The car wove between the traffic of the crowded streets like a huge shuttle. Both men in it were silent--Stuyvesant breathless and afraid to trust his hope, yet hoping; John despondent over Stuyv's going away. All that that gentleman had done came to John with a new force,--came when the possibility of losing Stuyv even for a few months was thrust before him.

Stuyvesant spoke:

"Takes so long to get out to-day," he said; "we seem to crawl. Look at that fellow ahead. Won't let us get past; have to crawl! Lord! Say, John, let me drive."

"I will not!" replied John with decision. "I have a distinct fondness for life. What's wrong with you?"

"Nothing," answered Stuyvesant loudly, "nothing at all!" Then he began to speak of certain affairs downtown, talking quickly, as if afraid of silence. John looked at him with wonder. It was very unlike Stuyvesant to be hectic. He recalled the mentioned disappointment. That, also, brought wonder. Stuyvesant didn't seem to care for girls. In business he seemed to get what he wanted. What could it be? Suddenly an idea, which seemed to John almost insane, flew across his mind.

He couldn't recognise it in the face of Cecilia's and Stuyvesant's open avoidance of each other, but in spite of that, the idea clung. "Got to see her, got to----" echoed in John's ears. He swallowed convulsively. If it were true! And it was not Marjory after all,--well, wouldn't he be the happiest fellow on earth? Well, rather!

The last months had brought John to a state of adoration of Cecilia and Stuyvesant. More than love it was. To be as sure of Stuyv's always closeness,--to have Cecilia so cared for.... "Can't you let her out a little?" he heard Stuyvesant say impatiently. John answered with a gentleness absolutely new, but it was not noticed. He ran the car faster and well, and his best efforts were greeted with: "This thing seems to crawl to-night. Darned if I don't want to get out and push!"

"You're in a hurry!" said John bravely.

"Oh, no, no!" answered Stuyvesant, looking on John suspiciously. Then he mopped his forehead, leaving it streaked with the dust that came off. "Hot," he said.

They rounded the last hill before the Madden gateway, and through a gap in some stately poplars they caught a glimpse of a white speck on an upper terrace.

"Cecilia!" blurted out Stuyvesant. "Oh, gosh! John, is my tie, that is, do I look----"

"Sure, you do," said John, comfortingly. Stuyvesant mopped some more. His face looked like a futurist painting of "The Dancers" or some one's aunt.

They rounded up the hill slowly. Evangeline bounded from the shrubbery and barked welcome.

"Evangeline," said Stuyvesant, as one in a trance.

"Yes," answered John; "Norah named him for Cecilia. Norah is an old family servant." Had Stuyvesant heard, he might have smiled, but Stuyvesant was past hearing.

"You poor boys!" said Cecilia. "How hot and tired you must be!" Then she looked at Stuyvesant and laughed. "I judge it was dusty?" she said.

"No, that is, I mean quite so," stuttered Stuyvesant. He stood before her silent, openly staring.

When John saw Cecilia flush he put his hand on Stuyvesant's arm. "Come on," he said. "We'll go brush up."

John's manner was as gentle as Cecilia's. Stuyvesant followed him. On the broad porch he paused and looked back.

Evangeline was telling Cecilia that he loved her, in dog fashion--wag code.

Cecilia patted him.

"Gosh!" said Stuyvesant, and then he mopped his forehead, making another picture in the dust.

Dusk came before dinner time. It crept down stealthily, like the thief it is of day. Shadows darkened and lengthened. Greens grew black. Cecilia in the half light on a wide porch watched a certain big and unusually gruff man. Something, she could see, was making him like a wistful boy--a boy so heart-set on his want that he fears the risk of refusal.

Cecilia thought of Marjory across the seas. There was a chance to play traitor--a chance to rekindle the little spark she had once fired in Stuyvesant. The idea danced about her soul and burnt its edges.

"Father McGowan-dear," she appealed inside, "please help me! I am trying, but I _am_ so little!" A breeze from the Sound came with a swish and moaned gently in and out among the loving arms of trees.

The lights in the dining room were soft. They shone gently down on a large bowl of pink roses which were in the centre of the table. Their hearts were a deeper colour and they nodded and seemed to talk when the steps of two pompous persons who passed things shook them.

Stuyvesant looked at Cecilia and then quickly away. He did not know what kind of a frock she wore except that it was white. He knew that she looked good, gentle and pure; that her eyes held the depths that hurts bring and the deep loyalty of love. There was a little droop to her lips that made him ache to see. He wondered at it, dared to hope that it had come because of him, and then he put the thought away. Unbelievably sweet it seemed.

And Cecilia?

"Marjory across the seas," she thought, "to subdue Jeremiah just a little----" She closed her eyes. "Oh dear!" she thought, "what _is_ the matter with me? These awful thoughts!" She opened them again and saw Jeremiah leaning on the table. His fists were closed about his knife and fork, and he held them upright, the handle ends resting on the cloth. John, curiously enough, did not seem bothered by this. He was watching Stuyvesant, who sat opposite.

"After that I started makin' bricks instead of layin' 'em. (Celie, ask that young feller to loan me a piece of bread. I want bread with my supper. I don't care what the style is.) So I begin to make bricks, an' when I look around and think that bricks done it all----" Jeremiah's voice faded. He left the rest to the imaginations of his listeners, while he laid a piece of bread flat on the table, and spread it _en masse_.

"I wisht my wife could have saw it," said Jeremiah as he loosened the piece of bread from the cloth. "She deserved everything. I never gave her nothing."

"You gave her a great deal," disagreed Cecilia. "You know you did! We were happy in that little flat. I remember that. We loved each other and we had enough to eat."

Cecilia was aware of Stuyvesant's eyes. They were so dear! She wondered if it was very wicked to love them, for she knew she always would.... And he had intimated that if Jeremiah were less prominent--Cecilia swallowed hard. The gods are visited with temptations, and too often they come to little humans. Cecilia was meeting hers. For the minute she felt anything possible, justifiable for the end she craved, and in the middle of her minute the white spark in her little heart flared.

"Papa," she said, "please tell Mr. Twombly about the time you hit the boss on the ear with a brick."

The request of that tale was her crucifixion on the cross of loyalty ... her proof beyond all doubt that her heart was in Jeremiah's rough old hands. Jeremiah looked pleased. His face lit rather pathetically. Cecilia answered his happy smile, and then she looked down at her plate. Her throat felt full and stiff. She found it hard to swallow.

Through a numbed consciousness she heard a long and much loved tale.

"I love him, I love him!" she chanted inside. "He and John are _everything_!" She looked up and found Stuyvesant looking at her. The way he looked made her gasp a little, and below the table she closed her small hands so tightly that her nails hurt her palms.

"An' then I sez, 'Yuh can lay yer own bricks,'" came in the voice of Jeremiah. "'An' here's one to begin with.' (It took him on the ear.)" He ended in parenthesis.

"Your stand for liberty--was--well--timed. It was--certainly the best thing you could have done," commented Stuyvesant in jerks. He was trying very hard not to look at Cecilia, and it was work not to.

"Celie," said Jeremiah, "what _has_ this fellow did to the potatoes? He does be-devil 'em so. He puts on so many airs that yuh hardly recognise 'em fer potatoes!"

"I don't know, dear," answered Cecilia, "but I'll see about it to-morrow."

"Mebbe Celie couldn't fry potatoes!" said Jeremiah. He smacked his lips loudly in remembrance. "These here furriners," he went on, "that we hire to cook,--poor things, _they_ don't know no better!" And thus Jeremiah disposed of French chefs. The lips of one of the pompous persons curled a little. The roses nodded and bobbed.

To Stuyvesant, who stared resolutely on them, they all whispered, "Cecilia!"

To Cecilia they shouted "Keefer, the butler."

To John they were lovelier that night from a new hope, and, of his father, a new understanding.

But to Jeremiah Madden they brought back only the heat of an overcrowded flat--the woman who held his heart dying by inches, when money might have made her live.... Money! ... A little tired-eyed girl struggling under a woman's load. A little boy who always cried for things he couldn't have.

"The bunnit with pink roses."

Life's question mark,--Fate's smile,--or God's hand?

Jeremiah looked away from the roses, and absently stuck the corner of his napkin in his collar. Then he looked about to see if any one had noticed, and hastily took it out.

Cecilia saw and her heart leaped with love. It seemed to her that the Saints had made Jeremiah do that then. Do it to show the little earth maiden her work in life. The taking from her father the shame which a son would have him feel, and giving him a substitute for the love that left him too soon,--too hungering.

They got up at last. Cecilia took a bobbing rose from the centrepiece. She began to break the thorns from it, but Stuyvesant's hands took it from her. He removed them methodically, and surely,--as he would. When he gave it back to her, there was nothing left to hurt.

"Thank you," she said.

"I wish I could take them out of the world for you," he answered gruffly. She shook as she crossed the room to where her father and John waited at the door. Her temptation was past. Her heart was strong, but she prayed that he would not say such things so much as if he meant them. It made it too hard.

"I am so weak," she thought, "so weak!"

Stuyvesant walked laggingly across the soft grass. John had said that he would find her by a white wall with a Greek relief, that that was her favourite spot. Stuyvesant knew that he dreamed of that spot because of her, but his connection with it influencing her, he never thought of. His spirit, always humble with her, knelt.

He thought of John's understanding, and whispering, "Good luck, Stuyv, dear!" and of his gasping, "John,--you'd be willing?" John had whacked him on the back and had answered convincingly. Then he'd gone unsteadily down the steps, and had lagged across the close-clipped grass. He wanted as he had never wanted anything to see her, but he was shaken and unsure ... sick from longing and fear.

Ahead of him in the half light he saw the stretch of wall standing out among the shadows.

He stopped, heart pounding, at the corner of the hedge-sheltered path. The little Irish maiden who was his key to heaven sat on the wall. Behind her the Sound was black. The soft stillness enveloped everything. The half night throbbed. Cecilia looked up, and saw the tall shadow in the shadows.

"John, dear?" she queried. Stuyvesant didn't answer for his voice was gone, but he stepped toward her. He put out a hand and laid it on a white wall. The world was reeling for him.

"Oh," she said, "I thought it was John, but--but you wanted to see me?"

He nodded.

"Marjory----" she began, then scolded herself for a too abrupt start. She drew a quick breath, and tried to control reason and tact. "She is so lovely, Mr. Stuyvesant," she went on, "but sometimes she doesn't let people know when she likes them. She's like that."

Cecilia stopped and gasped. It was harder than she had dreamed.

"Has she been a good friend to you?" asked Stuyvesant in a queer, tight voice.

"Oh, yes!" answered Cecilia, "so good! I do love her so much! I would do anything to make her happy!"

"You _darling_!" said K. Stuyvesant. He spoke loudly, but his words shook, for his heart was pounding with a sickening speed. With his words Cecilia caught her breath so deeply that it seemed a sob. Doubts vanished,--seemed incredible,--but she spoke what would always be her truth, though her heart famished from it. She looked Stuyvesant squarely in the eyes: "I love my father," she said, "and I am proud of him. I am proud to be his daughter."

"Of course you are," he answered. "You should be. Cecilia, I am very little, but I am large enough to see what you love in him. Have you misunderstood what I thought?"

She nodded. White, she was, and her eyes were on his face, imploring in their new hope.

"I loved you," said Stuyvesant, "on the boat. I saw how wonderful you were, but, Cecilia,--when I saw you here! When I see you turn and kiss your father when his eyes grow hurt because of John's unkindness.... Oh, my dear! Every instant of this year I've loved you, and more and more. I love you so ... No one could be worthy of you, but, little Saint,--no one could love you more! No one."

He stopped, choked. "I dream on my knees," he went on: "I'll dream of you until I die. But,--what's the use of saying all this? I love you! I love you so! That's everything."

He put a hand out toward her, then drew back. "Cecilia," he whispered, "you are so sweet!"

He looked down and drew his breath sharply. He wondered if she would ever speak.

He heard her slip from the wall.... Perhaps she would leave him without a word. Dully, he wondered how he could go on living if she did that.

And then the world turned over and then it ceased to be, for Cecilia's hands lay on his shoulders. He felt them move and creep up and around his neck. It was true.... He felt a wonderful, shaken strength.

"Cecilia! Cecilia!" she heard him gasp.

After a time she pushed him away and laughed tremulously. "Dearest Keefer Stuyvesant," she whispered shakily, "whose tears are these? Yours or mine?"

There was no room for laughter in Keefer Stuyvesant's soul. He drew her close again and answered gruffly: "There is no yours nor mine any more, little saint. They're ours, dearest,--ours. Oh, Cecilia, _gosh_, how I _love_ you!"

THE END

CHARMING BOOKS FOR GIRLS

May be had wherever books are sold. Ask for Grosset & Dunlap's list

WHEN PATTY WENT TO COLLEGE, By Jean Webster.

Illustrated by C. D. Williams.

One of the best stories of life in a girl's college that has ever been written. It is bright, whimsical and entertaining, lifelike, laughable and thoroughly human.

JUST PATTY, By Jean Webster.

Illustrated by C. M. Relyea.

Patty is full of the joy of living, fun-loving, given to ingenious mischief for its own sake, with a disregard for pretty convention which is an unfailing source of joy to her fellows.

THE POOR LITTLE RICH GIRL, By Eleanor Gates.

With four full page illustrations.

This story relates the experience of one of those unfortunate children whose early days are passed in the companionship of a governess, seldom seeing either parent, and famishing for natural love and tenderness. A charming play as dramatized by the author.

REBECCA OF SUNNYBROOK FARM, By Kate Douglas Wiggin.

One of the most beautiful studies of childhood--Rebecca's artistic, unusual and quaintly charming qualities stand on midst a circle of austere New Englanders. The stage version is making a phenomenal dramatic record.

NEW CHRONICLES OF REBECCA, By Kate Douglas Wiggin.

Illustrated by F. C. Yohn.

Additional episodes in the girlhood of this delightful heroine that carry Rebecca through various stages to her eighteenth birthday.

REBECCA MARY, By Annie Hamilton Donnell.

Illustrated by Elizabeth Shippen Green.

This author possesses the rare gift of portraying all the grotesque little joys and sorrows and scruples of this very small girl with a pathos that is peculiarly genuine and appealing.

Her Book and Heart, By George Madden Martin,

Illustrated by Charles Louis Hinton.

Emmy Lou is irresistibly lovable, because she is so absolutely real. She is just a bewitchingly innocent, hugable little maid. The book is wonderfully human.

STORIES OF RARE CHARM BY GENE STRATTON-PORTER

MICHAEL O'HALLORAN, Illustrated by Frances Rogers.

Michael is a quick-witted little Irish newsboy, living in Northern Indiana. He adopts a deserted little girl, a cripple. He also assumes the responsibility of leading the entire rural community upward and onward.

LADDIE. Illustrated by Herman Pfeifer.

This is a bright, cheery tale with the scenes laid in Indiana. The story is told by Little Sister, the youngest member of a large family, but it is concerned not so much with childish doings as with the love affairs of older members of the family. Chief among them is that of Laddie and the Princess, an English girl who has come to live in the neighborhood and about whose family there hangs a mystery.

THE HARVESTER. Illustrated by W. L. Jacobs.

"The Harvester," is a man of the woods and fields, and if the book had nothing in it but the splendid figure of this man it would be notable. But when the Girl comes to his "Medicine Woods," there begins a romance of the rarest idyllic quality.

FRECKLES. Illustrated.

Freckles is a nameless waif when the tale opens, but the way in which he takes hold of life; the nature friendships he forms in the great Limberlost Swamp; the manner in which everyone who meets him succumbs to the charm of his engaging personality; and his love-story with "The Angel" are full of real sentiment.

A GIRL OF THE LIMBERLOST. Illustrated.

The story of a girl of the Michigan woods; a buoyant, loveable type of the self-reliant American. Her philosophy is one of love and kindness towards all things; her hope is never dimmed. And by the sheer beauty of her soul, and the purity of her vision, she wins from barren and unpromising surroundings those rewards of high courage.

AT THE FOOT OF THE RAINBOW. Illustrations in colors.

The scene of this charming love story is laid in Central Indiana. The story is one of devoted friendship, and tender self-sacrificing love. The novel is brimful of the most beautiful word painting of nature, and its pathos and tender sentiment will endear it to all.

THE SONG OF THE CARDINAL.

Profusely illustrated.

A love ideal of the Cardinal bird and his mate, told with delicacy and humor.

LOPE DE VEGA

FUENTE OVEJUNA

Comedia

Edición revisada por Américo Castro

[Ilustración]

Madrid, 1919

Talleres "Calpe", Ríos Rosas, 24.--MADRID

Como tantas otras comedias de nuestro teatro, la presente--publicada en 1619--se basa en un hecho histórico: en 1476, los vecinos de Fuente Ovejuna (Córdoba) tomaron venganza, en la persona del comendador de la Orden de Calatrava, de las vejaciones inhumanas que aquél les hacía padecer. La crónica de Rades y Andrada narra prolijamente la justicia hecha por los aldeanos y la pesquisa ordenada por los Reyes Católicos.

Culmina en este drama el espíritu rústico y primitivo, que animó los ternas populares, muy activos dentro del teatro de nuestro siglo XVII, _siglo próximo a la Edad Media tanto por su pensamiento como por la forma de sentir la vida. Otras comedias de Lope poetizan la caballerosidad o la altivez aldeana_ (El alcalde de Zalamea, Peribáñez, El mejor alcalde, el rey, El villano en su rincón, etc.); FUENTE OVEJUNA, _empero, tiene como héroe a toda una villa, cuya fisonomía va concretándose en una firme progresión y acaba por adquirir tremenda e indivisible personalidad_.

Los aldeanos se rebelan contra una autoridad de privilegio y se someten a la monarquía nacional, que a la sazón representaba la uniformidad de la ley, un ideal más amplio, una mayor garantía de justicia para el pueblo. De esta suerte el drama es de una profunda lógica dentro de la historia: los vecinos de Fuente Ovejuna dan a su pleito la única solución jurídica y democrática entonces posible. Si sólo pensáramos que se trata de un cambio de señores y que la villa aclama a la autoridad que, con bárbara tozudez, desgarra las carnes de sus habitantes, entonces nos parecería poco motivada aquélla grandiosa conspiración.

Es curioso observar que FUENTE OVEJUNA _fué traducida al ruso y que sus representaciones provocaron frenético entusiasmo entre las masas oprimidas por el zarismo_.

Literariamente, tenemos aquí una de las más intensas producciones del teatro nacional. Lope supo conducir maravillosamente los hilos sentimentales que le ofrecía el episodio narrado en la crónica. Diversos chispazos heroicos van preparando el momento trágico en que los habitantes de la villa, sin flaquear, gimen bajo las cuerdas de la tortura. Pero esta suprema belleza, las múltiples situaciones de interés y el atractivo de los versos se manifestarán al lector sin necesidad de que el editor lo advierta.

Para imprimir esta comedia se ha tenido en cuenta el texto de la parte XII _de Lope, publicada en 1619. Los paréntesis cuadrados [] indican que se añade algo. No se advierte, sin embargo, la modificación de algunos pequeños errores del texto, de todo punto evidentes._

De esta comedia existe un manuscrito en la biblioteca de Parma, copia del texto de 1619, y otro no autógrafo, en poder de lord Ilchester (Londres), que no hemos podido consultar. Por consiguiente, carecemos de recursos para enmendar ciertos pasajes defectuosos de la obra, que quizá sólo se aclararían si se conservara el autógrafo. Cuando éstos existen se notan siempre grandes diferencias entre el autógrafo y el impreso de la época; FUENTE OVEJUNA, _pues, contiene también yerros, que no siempre podremos enmendar. El lector excusará este pequeño alarde de erudición; pero como las ediciones llamadas monumentales están hechas, en realidad, con una gran negligencia, no hemos podido limitarnos en este caso a reproducir, sin más, una edición anterior._

No hemos puesto más indicaciones escénicas que las que figuran en el original. En el siglo XVII _apenas se usaban las decoraciones, y los cambios y movimientos escénicos se deducían de las palabras de los actores. Ahora el lector tendrá que deducirlos del contexto. Lo creemos preferible a alterar el carácter original de la obra con adiciones personales._

COMEDIA FAMOSA

DE

FUENTE OVEJUNA

Hablan en ella las personas siguientes:

FERNÁN GÓMEZ [_comendador_]. ORTUÑO. FLORES. _El_ MAESTRE DE CALATRAVA. PASCUALA. LAURENCIA. MENGO. BARRILDO. FRONDOSO. JUAN ROJO. ESTEBAN, ALONSO, _alcaldes._ REY DON FERNANDO. REINA DOÑA ISABEL. _Un_ REGIDOR. CIMBRANOS, _soldado._ JACINTA, _labradora._ _Un_ MUCHACHO. _Algunos_ LABRADORES. _Un_ JUEZ. _La_ MÚSICA. [DON MANRIQUE]. [LEONELO].

ACTO PRIMERO

ACTO PRIMERO

(_Salen el_ COMENDADOR, FLORES _y_ ORTUÑO, _criados._)

COMENDADOR

¿Sabe el maestre que estoy en la villa?

FLORES

Ya lo sabe.

ORTUÑO

Está, con la edad, más grave.

COMENDADOR

Y ¿sabe también que soy Fernán Gómez de Guzmán?

FLORES

Es muchacho, no te asombre.

COMENDADOR

Cuando no sepa mi nombre, ¿no le sabrá el que me dan de comendador mayor?

ORTUÑO

No falta quien le aconseje que de ser cortés se aleje.

COMENDADOR

Conquistará poco amor. Es llave la cortesía para abrir la voluntad; y para la enemistad la necia descortesía.

ORTUÑO

Si supiese un descortés cómo lo aborrecen todos --y querrían de mil modos poner la boca a sus pies--, antes que serlo ninguno, se dejaría morir.

FLORES

¡Qué cansado es de sufrir! ¡Qué áspero y qué importuno! Llaman la descortesía necedad en los iguales, porque es entre desiguales linaje de tiranía. Aquí no te toca nada: que un muchacho aun no ha llegado a saber qué es ser amado.

COMENDADOR

La obligación de la espada que se ciñó, el mismo día que la cruz de Calatrava le cubrió el pecho, bastaba para aprender cortesía.

FLORES

Si te han puesto mal con él, presto le conocerás.

ORTUÑO

Vuélvete, si en duda estás.

COMENDADOR

Quiero ver lo que hay en él.

(_Sale el_ MAESTRE DE CALATRAVA _y acompañamiento._)

MAESTRE

Perdonad, por vida mía, Fernán Gómez de Guzmán; que agora nueva me dan que en la villa estáis.

COMENDADOR

Tenía muy justa queja de vos; que el amor y la crianza me daban más confianza, por ser, cual somos los dos, vos maestre en Calatrava, yo vuestro comendador y muy vuestro servidor.

MAESTRE

Seguro[1], Fernando, estaba de vuestra buena venida. Quiero volveros a dar los brazos.

[1] _Seguro_, descuidado, ajeno.

COMENDADOR

Debéisme honrar; que he puesto por vos la vida entre diferencias tantas, hasta suplir vuestra edad el pontífice.

MAESTRE

Es verdad. Y por las señales santas que a los dos cruzan el pecho, que os lo pago en estimaros, y como a mi padre honraros.

COMENDADOR

De vos estoy satisfecho.

MAESTRE

¿Qué hay de guerra por allá?

COMENDADOR

Estad atento, y sabréis, la obligación que tenéis.

MAESTRE

Decid que ya lo estoy, ya.

COMENDADOR

Gran maestre don Rodrigo Téllez Girón, que a tan alto lugar os trajo el valor de aquel vuestro padre claro, que, de ocho años, en vos renunció su maestrazgo, que después por más seguro juraron y confirmaron reyes y comendadores, dando el pontífice santo Pío segundo sus bulas, y después las suyas Paulo para que don Juan Pacheco, gran maestre de Santiago, fuese vuestro coadjutor: ya que es muerto, y que os han dado el gobierno sólo a vos, aunque de tan pocos años, advertid que es honra vuestra seguir en aqueste caso la parte de vuestros deudos; porque muerto Enrique cuarto, quieren que al rey don Alonso de Portugal, que ha heredado, por su mujer, a Castilla, obedezcan sus vasallos; que aunque pretende[2] lo mismo, por Isabel, don Fernando, gran príncipe de Aragón, no con derecho tan claro a vuestros deudos; que, en fin, no presumen que hay engaño en la sucesión de Juana[3], a quien vuestro primo hermano tiene agora en su poder. Y así vengo a aconsejaros que juntéis los caballeros de Calatrava en Almagro, y a Ciudad Real toméis, que divide como paso a Andalucía y Castilla, para mirarlas a entrambas[4]. Poca gente es menester, porque tienen por soldados solamente sus vecinos y algunos pocos hidalgos, que defienden a Isabel y llaman rey a Fernando. Será bien que deis asombro, Rodrigo, aunque niño, a cuantos dicen que es grande esa cruz para vuestros hombros flacos. Mirad los condes de Urueña, de quien venís, que mostrando os están desde la fama los laureles que ganaron; los marqueses de Villena, y otros capitanes, tantos, que las alas de la fama apenas pueden llevarlos. Sacad esa blanca espada, que habéis de hacer, peleando, tan roja como la cruz; porque no podré llamaros maestre de la cruz roja que tenéis al pecho, en tanto que tenéis la blanca espada; que una al pecho y otra al lado, entrambas han de ser rojas; y vos, Girón soberano, capa del templo inmortal de vuestros claros pasados.

[2] _El original_, pretenden.

[3] Juana la Beltraneja, hija, según se supuso, de D. Beltrán de la Cueva, privado del rey Enrique IV y amante de la reina.

[4] _El original_, entrambos.

MAESTRE

Fernán Gómez, estad cierto que en esta parcialidad, porque veo que es verdad, con mis deudos me concierto. Y si importa, como paso, a Ciudad Real mi intento, veréis que como violento rayo sus muros abraso. No porque es muerto mi tío, piensen de mis pocos años los propios y los extraños que murió con él mi brío. Sacaré la blanca espada, para que quede su luz de la color de la cruz, de roja sangre bañada. Vos, ¿adónde residís? ¿Tenéis algunos soldados?

COMENDADOR

Poco, pero mis criados; que si dellos os servís, pelearán como leones. Ya veis que en Fuente Ovejuna hay gente humilde, y alguna no enseñada en escuadrones, sino en campos y labranzas.

MAESTRE

¿Allí residís?

COMENDADOR

Allí de mi encomienda escogí casa entre aquestas mudanzas. Vuestra gente se registre; que no quedará vasallo.

MAESTRE

Hoy me veréis a caballo, poner la lanza en el ristre.

(_Vanse, y salen_ PASCUALA _y_ LAURENCIA.)

LAURENCIA

¡Mas que nunca acá volviera!

PASCUALA

Pues a la he que pensé que cuando te lo conté, más pesadumbre te diera.

LAURENCIA

¡Plega al cielo que jamás le vea en Fuente Ovejuna!

PASCUALA

Yo, Laurencia, he visto alguna tan brava, y pienso que más; y tenía el corazón brando como una manteca.

LAURENCIA

Pues ¿hay encina tan seca como esta mi condición?

PASCUALA

Anda ya; que nadie diga: de esta agua no beberé.

LAURENCIA

¡Voto al sol que lo diré, aunque el mundo me desdiga! ¿A qué efeto fuera bueno querer a Fernando yo? ¿Casarme con él?

PASCUALA

No.

LAURENCIA

Luego la infamia condeno. ¡Cuántas mozas en la villa, del comendador fiadas, andan ya descalabradas!

PASCUALA

Tendré yo por maravilla que te escapes de su mano.

LAURENCIA

Pues en vano es lo que ves, porque ha que me sigue un mes, y todo, Pascuala, en vano. Aquel Flores, su alcahuete, y Ortuño, aquel socarrón, me mostraron un jubón, una sarta y un copete. Dijéronme tantas cosas de Fernando, su señor, que me pusieron temor; mas no serán poderosas para contrastar mi pecho.

PASCUALA

¿Dónde te hablaron?

LAURENCIA

Allá en el arroyo, y habrá seis días.

PASCUALA

Y yo sospecho que te han de engañar, Laurencia.

LAURENCIA

¿A mí?

PASCUALA

Que no, sino al cura.

LAURENCIA

Soy, aunque polla, muy dura yo para su reverencia. Pardiez, más precio poner, Pascuala de madrugada, un pedazo de lunada[5] al huego para comer, con tanto zalacatón[6] de una rosca que yo amaso, y hurtar a mi madre un vaso del pegado canjilón[7]; y más precio al mediodía ver la vaca entre las coles, haciendo mil caracoles con espumosa armonía; y concertar, si el camino me ha llegado a causar pena, casar una berenjena con otro tanto tocino; y después un pasa-tarde, mientras la cena se aliña, de una cuerda de mi viña, que Dios de pedrisco guarde; y cenar un salpicón con su aceite y su pimienta, y irme a la cama contenta, y al «inducas tentación» rezalle mis devociones, que cuantas raposerías, con su amor y sus porfías, tienen estos bellacones; porque todo su cuidado, después de darnos disgusto, es anochecer con gusto y amanecer con enfado.

[5] _Lunada_, pernil.

[6] _Zalacatón_, trozo de pan.

[7] Vasija untada de pez.

PASCUALA

Tienes, Laurencia, razón; que en dejando de querer, más ingratos suelen ser que al villano el gorrión. En el invierno, que el frío tiene los campos helados, decienden de los tejados, diciéndole «tío, tío», hasta llegar a comer las migajas de la mesa; mas luego que el frío cesa, y el campo ven florecer, no bajan diciendo «tío», del beneficio olvidados, mas saltando en los tejados, dicen: «judío, judío». Pues tales los hombres son: cuando nos han menester somos su vida, su ser, su alma, su corazón; pero pasadas las ascuas, las tías somos judías, y en vez de llamarnos tías, anda el nombre de las pascuas[8].

[8] _Nombre de las pascuas_, «putas, bellacas, alcahuetas». (Correas, _Vocabulario._)

LAURENCIA

No fiarse de ninguno.

PASCUALA

Lo mismo digo, Laurencia.

(_Salen_ MENGO _y_ BARRILDO _y_ FRONDOSO.)

FRONDOSO

En aquesta diferencia andas, Barrildo, importuno.

BARRILDO

A lo menos aquí está quien nos dirá lo más cierto.

MENGO

Pues hagamos un concierto antes que lleguéis allá, y es, que si juzgan por mí, me dé cada cual la prenda, precio de aquesta contienda.

BARRILDO

Desde aquí digo que sí. Mas si pierdes, ¿qué darás?

MENGO

Daré mi rabel de boj, que vale más que una troj, porque yo le estimo en más.

BARRILDO

Soy contento.

FRONDOSO

Pues lleguemos. Dios os guarde, hermosas damas.

LAURENCIA

¿Damas, Frondoso, nos llamas?

FRONDOSO

Andar al uso queremos: al bachiller, licenciado; al ciego, tuerto; al bisojo, bizco; resentido, al cojo, y buen hombre al descuidado. Al ignorante, sesudo; al mal galán, soldadesca; a la boca grande, fresca, y al ojo pequeño, agudo. Al pleitista, diligente; gracioso, al entremetido[9]; al hablador, entendido, y al insufrible, valiente. Al cobarde, para poco; al atrevido, bizarro; compañero, al que es un jarro, y desenfadado, al loco. Gravedad, al descontento; a la calva, autoridad; donaire, a la necedad, y al pie grande, buen cimiento. Al buboso, resfriado; comedido, al arrogante; al ingenioso, constante; al corcovado, cargado. Esto [al] llamaros imito, damas, sin pasar de aquí; porque fuera hablar así proceder en infinito.

[9] _El original_, al gracioso, entremetido.

LAURENCIA

Allá en la ciudad, Frondoso, llámase por cortesía de esa suerte; y a fe mía, que hay otro más riguroso y peor vocabulario en las lenguas descorteses.

FRONDOSO

Querría que lo dijeses.

LAURENCIA

Es todo a esotro contrario: al hombre grave, enfadoso; venturoso, al descompuesto[10]; melancólico, al compuesto, y al que reprehende, odioso. Importuno al que aconseja; al liberal, moscatel[11]; al justiciero, cruel, y al que es piadoso, madeja[12]. Al que es constante, villano; al que es cortés, lisonjero; hipócrita, al limosnero, y pretendiente, al cristiano. Al justo mérito, dicha; a la verdad, imprudencia; cobardía, a la paciencia, y culpa, a lo que es desdicha. Necia, a la mujer honesta; mal hecha, a la hermosa y casta, y a la honrada... Pero basta; que esto basta por respuesta.

[10] _Descompuesto_, audaz, atrevido.

[11] _Moscatel_, hombre pesado e importuno. _El original_, liberal, al moscatel.

[12] _Madeja_, hombre flojo y dejado.

MENGO

Digo que eres el dimuño.

BARRILDO

Soncas[13] que lo dice mal.

[13] _Soncas_, a fe, en verdad.

MENGO

Apostaré que la sal la echó el cura con el puño.

LAURENCIA

¿Qué contienda os ha traído si no es que mal lo entendí?

FRONDOSO

Oye, por tu vida.

LAURENCIA

Di.

FRONDOSO

Préstame, Laurencia, oído.

LAURENCIA

Como prestado, y aun dado. Desde agora os doy el mío.

FRONDOSO

En tu discreción confío.

LAURENCIA

¿Qué es lo que habéis apostado?

FRONDOSO

Yo y Barrildo contra Mengo.

LAURENCIA

¿Qué dice Mengo?

BARRILDO

Una cosa que, siendo cierta y forzosa, la niega.

MENGO

A negarla vengo, porque yo sé que es verdad.

LAURENCIA

¿Qué dice?

BARRILDO

Que no hay amor.

LAURENCIA

Generalmente, es rigor.

BARRILDO

Es rigor y es necedad. Sin amor, no se pudiera ni aun el mundo conservar.

MENGO

Yo no sé filosofar; leer, ¡ojalá supiera! Pero si los elementos en discordia eterna viven, y de los mismos reciben nuestros cuerpos alimentos, cólera y melancolía, flema y sangre, claro está.

BARRILDO

El mundo de acá y de allá, Mengo, todo es armonía. Armonía es puro amor, porque el amor es concierto.

MENGO

Del natural, os advierto que yo no niego el valor. Amor hay, y el que entre sí gobierna todas las cosas, correspondencias forzosas de cuanto se mira aquí; y yo jamás he negado que cada cual tiene amor correspondiente a su humor, que le conserva en su estado. Mi mano al golpe que viene mi cara defenderá; mi pie, huyendo, estorbará el daño que el cuerpo tiene. Cerraránse mis pestañas si al ojo le viene mal, porque es amor natural.

PASCUALA

Pues ¿de qué nos desengañas?

MENGO

De que nadie tiene amor mas que a su misma persona.

PASCUALA

Tú mientes, Mengo, y perdona; porque ¿es [mentira][14] el rigor con que un hombre a una mujer, o un animal quiere y ama su semejante?

[14] _El original_, materia.

MENGO

Eso llama amor propio, y no querer. ¿Qué es amor?

LAURENCIA

Es un deseo de hermosura.

MENGO

Esa hermosura ¿por qué el amor la procura?

LAURENCIA

Para gozarla.

MENGO

Eso creo. Pues ese gusto que intenta, ¿no es para él mismo?

LAURENCIA

Es así.

MENGO

Luego, ¿por quererse a sí busca el bien que le contenta?

LAURENCIA

Es verdad.

MENGO

Pues de ese modo no hay amor, sino el que digo, que por mi gusto le sigo, y quiero dármele en todo.

BARRILDO

Dijo el cura del lugar cierto día en el sermón que había cierto Platón que nos enseñaba a amar; que éste amaba el alma sola y la virtud de lo amado.

PASCUALA

En materia habéis entrado que, por ventura, acrisola los caletres de los sabios en sus academias y escuelas.

LAURENCIA

Muy bien dice, y no te muelas, en persuadir sus agravios. Da gracias, Mengo, a los cielos, que te hicieron sin amor.

MENGO

¿Amas tú?

LAURENCIA

Mi propio honor.

FRONDOSO

Dios te castigue con celos.

BARRILDO

¿Quién gana?

PASCUALA

Con la quistión podéis ir al sacristán, porque él o el cura os darán bastante satisfación. Laurencia no quiere bien, yo tengo poca experiencia. ¿Cómo daremos sentencia?

FRONDOSO

¿Qué mayor que ese desdén?

(_Sale_ FLORES.)

FLORES

Dios guarde a la buena gente.

PASCUALA

Este es del comendador criado.

LAURENCIA

¡Gentil azor! ¿De adónde bueno, pariente?

FLORES

¿No me veis a lo soldado?

LAURENCIA

¿Viene don Fernando acá?

FLORES

La guerra se acaba ya, puesto que[15] nos ha costado alguna sangre y amigos.

[15] _Puesto que_, aunque.

FRONDOSO

Contadnos cómo pasó.

FLORES

¿Quién lo dirá como yo, siendo mis ojos testigos? Para emprender la jornada de esta ciudad, que ya tiene nombre de Ciudad-Real, juntó el gallardo maestre dos mil lucidos infantes de sus vasallos valientes y trecientos de a caballo de seglares y de freiles; porque la cruz roja obliga cuantos al pecho la tienen, aunque sean de orden sacro; mas contra moros, se entiende. Salió el muchacho bizarro con una casaca verde, bordada de cifras de oro, que sólo los brazaletes por las mangas descubrían, que seis alamares prenden. Un corpulento bridón, rucio rodado, que al Betis bebió el agua, y en su orilla despuntó la grama fértil; el codón labrado en cintas de ante, y el rizo copete cogido en blancas lazadas, que con las moscas de nieve que bañan la blanca piel iguales labores teje. A su lado Fernán Gómez, vuestro señor, en un fuerte melado, de negros cabos, puesto que con blanco bebe[16]. Sobre turca jacerina, peto y espaldar luciente, con naranjada las saca (?), que de oro y perlas guarnece. El morrión, que coronado con blancas plumas, parece que del color naranjado aquellos azares vierte; ceñida al brazo una liga roja y blanca, con que mueve un fresno entero por lanza, que hasta en Granada le temen. La ciudad se puso en arma; dicen que salir no quieren de la corona real, y el patrimonio defienden. Entróla bien resistida, y el maestre a los rebeldes y a los que entonces trataron su honor injuriosamente mandó cortar las cabezas, y a los de la baja plebe, con mordazas en la boca, azotar públicamente. Queda en ella tan temido y tan amado, que creen que quien en tan pocos años pelea, castiga y vence, ha de ser en otra edad rayo del Africa fértil, que tantas lunas azules a su roja cruz sujete. Al comendador y a todos ha hecho tantas mercedes, que el saco de la ciudad el de su hacienda parece. Mas ya la música suena: recebilde alegremente, que al triunfo, las voluntades son los mejores laureles.

[16] «Frase que se entiende de los caballos, para dar a entender que tienen alguna señal blanca en el hocico, de la cual se infiere que serán buenos y leales.» (_Diccionario de Autoridades_, de 1726.)

(_Salen el_ COMENDADOR _y_ ORTUÑO; MÚSICOS; JUAN ROJO _y_ ESTEBAN, ALONSO, _alcaldes._)

(_Cantan._)

Sea bien venido el comendadore de rendir las tierras y matar los hombres. ¡Vivan los Guzmanes! ¡Vivan los Girones! Si en las paces blando, dulce en las razones. Venciendo moricos, fuertes como un roble, de Ciudad-Reale viene vencedore; que a Fuente Ovejuna trae los sus pendones. ¡Viva muchos años, viva Fernán Gómez!

COMENDADOR

Villa, yo os agradezco justamente el amor que me habéis aquí mostrado.

ALONSO

Aun no muestra una parte del que siente. Pero, ¿qué mucho que seáis amado, mereciéndolo vos?

ESTEBAN

Fuente Ovejuna y el regimiento[17] que hoy habéis honrado, que recibáis os ruega y importuna un pequeño presente, que esos carros traen, señor, no sin vergüenza alguna, de voluntades y árboles bizarros, más que de ricos dones. Lo primero traen dos cestas de polidos barros; de gansos viene un ganadillo entero, que sacan por las redes las cabezas, para cantar vueso valor guerrero. Diez cebones en sal, valientes piezas, sin otras menudencias y cecinas; y más que guantes de ámbar, sus cortezas. Cien pares de capones y gallinas, que han dejado viudos a sus gallos en las aldeas que miráis vecinas. Acá no tienen armas ni caballos, no jaeces bordados de oro puro, si no es oro el amor de los vasallos. Y porque digo puro, os aseguro que vienen doce cueros, que aun en cueros por enero podéis guardar un muro, si de ellos aforráis vuestros guerreros, mejor que de las armas aceradas; que el vino suele dar lindos aceros. De quesos y otras cosas no excusadas no quiero daros cuenta: justo pecho de voluntades que tenéis ganadas; y a vos y a vuestra casa, buen provecho.

[17] _Regimiento_, el concejo municipal.

COMENDADOR

Estoy muy agradecido. Id, regimiento, en buen hora.

ALONSO

Descansad, señor, agora, y seáis muy bien venido; que esta espadaña que veis y juncia a vuestros umbrales, fueran perlas orientales, y mucho más merecéis, a ser posible a la villa.

COMENDADOR

Así lo creo, señores. Id con Dios.

ESTEBAN

Ea, cantores, vaya otra vez la letrilla.

(_Cantan._)

Sea bien venido el comendadore de rendir las tierras y matar los hombres.

(_Vanse._)

COMENDADOR

Esperad vosotras dos.

LAURENCIA

¿Qué manda su señoría?

COMENDADOR

¡Desdenes el otro día, pues, conmigo! ¡Bien por Dios!

LAURENCIA

¿Habla contigo, Pascuala?

PASCUALA

Conmigo no, tirte ahuera[18].

[18] _Tirte ahuera_, ¡anda allá!

COMENDADOR

Con vos hablo, hermosa fiera, y con esotra zagala. ¿Mías no sois?

PASCUALA

Sí, señor; mas no para casos tales.

COMENDADOR

Entrad, pasad los umbrales; hombres hay, no hayáis temor.

LAURENCIA

Si los alcaldes entraran (que de uno soy hija yo), bien huera entrar; mas si no...

COMENDADOR

Flores...

FLORES

Señor...

COMENDADOR

¿Qué reparan en no hacer lo que les digo?

FLORES

Entra, pues.

LAURENCIA

No nos agarre.

FLORES

Entrad; que sois necias.

PASCUALA

Arre; que echaréis luego el postigo.

FLORES

Entrad; que os quiere enseñar lo que trae de la guerra.

COMENDADOR [_Aparte a_ ORTUÑO.]

Si entraron. Ortuño, cierra.

LAURENCIA

Flores, dejadnos pasar.

ORTUÑO

¿También venís presentadas con lo demás?

PASCUALA

¡Bien a fe! Desvíese, no le dé...

FLORES

Basta; que son extremadas.

LAURENCIA

¿No basta a vueso señor tanta carne presentada?

ORTUÑO

La vuestra es la que le agrada.

LAURENCIA

Reviente de mal dolor.

(_Vanse._)

FLORES

¡Muy buen recado llevamos! No se ha de poder sufrir lo que nos ha de decir cuando sin ellas nos vamos.

ORTUÑO

Quien sirve se obliga a esto. Si en algo desea medrar, o con paciencia ha de estar, o ha despedirse de presto.

(_Vanse los dos y salgan el_ REY DON FERNANDO, _la_ REINA DOÑA ISABEL, MANRIQUE _y acompañamiento._)

ISABEL

Digo, señor, que conviene el no haber descuido en esto, por ver a Alfonso en tal puesto, y su ejército previene. Y es bien ganar por la mano antes que el daño veamos; que si no lo remediamos, el ser muy cierto está llano.

REY

De Navarra y de Aragón está el socorro seguro, y de Castilla procuro hacer la reformación de modo, que el buen suceso con la prevención se vea.

ISABEL

Pues vuestra majestad crea que el buen fin consiste en esto.

MANRIQUE

Aguardando tu licencia dos regidores están de Ciudad Real: ¿entrarán?

REY

No les nieguen mi presencia.

(_Salen dos_ REGIDORES _de Ciudad Real._)

REGIDOR 1.º

Católico rey Fernando, a quien ha enviado el cielo, desde Aragón a Castilla, para bien y amparo nuestro: en nombre de Ciudad Real a vuestro valor supremo humildes nos presentamos, el real amparo pidiendo. A mucha dicha tuvimos tener título de vuestros; pero pudo derribarnos deste honor el hado adverso. El famoso don Rodrigo Téllez Girón, cuyo esfuerzo es en valor extremado, aunque es en la edad tan tierno, maestre de Calatrava, él, ensanchar pretendiendo el honor de la encomienda, nos puso apretado cerco. Con valor nos prevenimos, a su fuerza resistiendo, tanto, que arroyos corrían de la sangre de los muertos. Tomó posesión,

en fin; pero no llegara a hacerlo, a no le dar Fernán Gómez orden, ayuda y consejo. El queda en la posesión, y sus vasallos seremos, suyos, a nuestro pesar, a no remediarlo presto.

REY

¿Dónde queda Fernán Gómez?

REGIDOR 1.º

En Fuente Ovejuna creo, por ser su villa, y tener en ella casa y asiento. Allí, con más libertad de la que decir podemos, tiene a los súbditos suyos de todo contento ajenos.

REY

¿Tenéis algún capitán?

REGIDOR 2.°

Señor, el no haberle es cierto, pues no escapó ningún noble de preso, herido o de muerto.

ISABEL

Ese caso no requiere ser despacio remediado; que es dar al contrario osado el mismo valor que adquiere; y puede el de Portugal, hallando puerta segura, entrar por Extremadura y causamos mucho mal.

REY

Don Manrique, partid luego, llevando dos compañías; remediad sus demasías, sin darles ningún sosiego. El conde de Cabra ir puede con vos; que es Córdoba osado, a quien nombre de soldado todo el mundo le concede; que éste es el medio mejor que la ocasión nos ofrece.

MANRIQUE

El acuerdo me parece como de tan gran valor. Pondré límite a su exceso, si el vivir en mí no cesa.

ISABEL

Partiendo vos a la empresa, seguro está el buen suceso.

(_Vanse todos y salen_ LAURENCIA _y_ FRONDOSO.)

LAURENCIA

A medio torcer los paños, quise, atrevido Frondoso, para no dar que decir, desviarme del arroyo; decir a tus demasías que murmura el pueblo todo, que me miras y te miro, y todos nos traen sobre ojo. Y como tú eres zagal, de los que huellan, brioso, y excediendo a los demás, vistes bizarro y costoso, en todo el lugar no hay moza, o mozo en el prado o soto, que no se afirme diciendo que ya para en uno somos; y esperan todos el día que el sacristán Juan Chamorro nos eche de la tribuna, en dejando los piporros[19]. Y mejor sus trojes vean de rubio trigo en agosto atestadas y colmadas, y sus tinajas de mosto, que tal imaginación me ha llegado a dar enojo: ni me desvela ni aflige, ni en ella el cuidado pongo.

[19] Instrumento de música, llamado también _bajón_.

FRONDOSO

Tal me tienen tus desdenes, bella Laurencia, que tomo, en el peligro de verte, la vida, cuando te oigo. Si sabes que es mi intención el desear ser tu esposo, mal premio das a mi fe.

LAURENCIA

Es que yo no sé dar otro.

FRONDOSO

¿Posible es que no te duelas de verme tan cuidadoso, y que imaginando en ti, ni bebo, duermo ni como? ¿Posible es tanto rigor en ese angélico rostro? ¡Viven los cielos que rabio!

LAURENCIA

Pues salúdate[20], Frondoso.

[20] _Saludar_, usar de ciertas fórmulas (hacer cruces con saliva, etcétera), pretendiendo curar la rabia y otros males.

FRONDOSO

Ya te pido yo salud, y que ambos, como palomos, estemos, juntos los picos, con arrullos sonorosos, después de damos la Iglesia...

LAURENCIA

Dilo a mi tío Juan Rojo; que aunque no te quiero bien, ya tengo algunos asomos.

FRONDOSO

¡Ay de mí! El señor es éste.

LAURENCIA

Tirando viene a algún corzo. Escóndete en esas ramas.

FRONDOSO

Y ¡con qué celos me escondo!

(_Sale el_ COMENDADOR.)

COMENDADOR

No es malo venir siguiendo un corcillo temeroso, y topar tan bella gama.

LAURENCIA

Aquí descansaba un poco de haber lavado unos paños; y así, al arroyo me tomo, si manda su señoría.

COMENDADOR

Aquesos desdenes toscos afrentan, bella Laurencia, las gracias que el poderoso cielo te dió, de tal suerte, que vienes a ser un monstruo. Mas si otras veces pudiste huir mi ruego amoroso, agora no quiere el campo, amigo secreto y solo; que tú sola no has de ser tan soberbia, que tu rostro huyas al señor que tienes, teniéndome a mí en tan poco. ¿No se rindió Sebastiana, mujer de Pedro Redondo, con ser casadas entrambas, y la de Martín del Pozo, habiendo apenas pasado dos días del desposorio?

LAURENCIA

Esas, señor, ya tenían, de haber andado con otros, el camino de agradaros; porque también muchos mozos merecieron sus favores. Id con Dios, tras vueso corzo; que a no veros con la cruz, os tuviera por demonio, pues tanto me perseguís.

COMENDADOR

¡Qué estilo tan enfadoso! Pongo la ballesta en tierra, ...[21] y a la práctica de manos reduzgo melindres.

[21] Falta un verso para el romance, pero no para el sentido.

LAURENCIA

¡Cómo! ¿Eso hacéis? ¿Estáis en vos?

(_Sale_ FRONDOSO _y toma la ballesta._)

COMENDADOR

No te defiendas.

FRONDOSO [_Aparte._]

Si tomo la ballesta, ¡vive el cielo que no la ponga en el hombro!

COMENDADOR

Acaba, ríndete.

LAURENCIA

¡Cielos, ayudadme agora!

COMENDADOR

Solos estamos; no tengas miedo.

FRONDOSO

Comendador generoso, dejad la moza, o creed que de mi agravio y enojo será blanco vuestro pecho, aunque la cruz me da asombro.

COMENDADOR

¡Perro, villano!...

FRONDOSO

No hay perro. Huye, Laurencia.

LAURENCIA

Frondoso, mira lo que haces.

FRONDOSO

Vete.

(_Vase._)

COMENDADOR

¡Oh, mal haya el hombre loco, que se desciñe la espada! Que, de no espantar medroso la caza, me la quité.

FRONDOSO

Pues, pardiez, señor, si toco la nuez[22], que os he de apiolar.

[22] Botón con que se disparaba la ballesta.

COMENDADOR

Ya es ida. Infame, alevoso, suelta la ballesta luego. Suéltala, villano.

FRONDOSO

¿Cómo? Que me quitaréis la vida. Y advertid que amor es sordo, y que no escucha palabras el día que está en su trono.

COMENDADOR

Pues ¿la espa[l]da ha de volver un hombre tan valeroso a un villano? Tira, infame, tira, y guárdate; que rompo las leyes de caballero.

FRONDOSO

Eso no. Yo me conformo con mi estado, y pues me es guardar la vida forzoso, con la ballesta me voy.

COMENDADOR

¡Peligro extraño y notorio! Mas yo tomaré venganza del agravio y del estorbo. ¡Que no cerrara con él! ¡Vive el cielo, que me corro!

ACTO SEGUNDO DE FUENTE OVEJUNA

ACTO SEGUNDO DE FUENTE OVEJUNA

(_Salen_ ESTEBAN _y_ REGIDOR 1.°)

ESTEBAN

Así tenga salud, como parece, que no se saque más agora el pósito. El año apunta mal, y el tiempo crece, y es mejor que el sustento esté en depósito, aunque lo contradicen más de trece.

REGIDOR 1.°

Yo siempre he sido, al fin, de este propósito, en gobernar en paz esta república.

ESTEBAN

Hagamos de ello a Fernán Gómez súplica. No se puede sufrir que estos astrólogos, en las cosas futuras ignorantes[23], nos quieran persuadir con largos prólogos los secretos a Dios sólo importantes. ¡Bueno es que, presumiendo de teólogos, hagan un tiempo el que[24] después y antes! Y pidiendo el presente lo importante, al más sabio veréis más ignorante. ¿Tienen ellos las nubes en su casa y el proceder de las celestes lumbres? ¿Por dónde ven lo que en el cielo pasa, para damos con ello pesadumbres? Ellos en [el] sembrar nos ponen tasa: daca el trigo, cebada y las legumbres, calabazas, pepinos y mostazas... Ellos son, a la fe, las calabazas. Luego cuentan que muere una cabeza, y después viene a ser en Transilvania; que el vino será poco, y la cerveza sobrará por las partes de Alemania; que se helará en Gascuña la cereza, y que habrá muchos tigres en Hircania. Y al cabo, al cabo, se siembre o no se siembre, el año se remata por diciembre.

[23] _El original_, y ignorantes.

[24] El que será después y fué antes.

(_Salen el licenciado_ LEONELO _y_ BARRILDO.)

LEONELO

A fe que no ganéis la palmatoria[25], porque ya está ocupado el mentidero.

[25] Al muchacho que llegaba primero a la escuela le daban la palmeta para que aplicase los castigos.

BARRILDO

¿Cómo os fué en Salamanca?

LEONELO

Es larga historia.

BARRILDO

Un Bártulo seréis.

LEONELO

Ni aun un barbero. Es, como digo, cosa muy notoria en esta facultad lo que os refiero.

BARRILDO

Sin duda que venís buen estudiante.

LEONELO

Saber he procurado lo importante.

BARRILDO

Después que vemos tanto libro impreso, no hay nadie que de sabio no presuma.

LEONELO

Antes que ignoran más siento por eso, por no se reducir a breve suma; porque la confusión, con el exceso, los intentos resuelve en vana espuma; y aquel que de leer tiene más uso, de ver letreros sólo está confuso. No niego yo que de[26] imprimir el arte mil ingenios sacó de entre la jerga, y que parece que en sagrada parte sus obras guarda y contra el tiempo alberga; éste las distribuye y las reparte. Débese esta invención a Gutemberga, un famoso tudesco de Maguncia, en quien la fama su valor renuncia. Mas muchos que opinión tuvieron grave, por imprimir sus obras la perdieron; tras esto, con el nombre del que sabe, muchos sus ignorancias imprimieron. Otros, en quien la baja envidia cabe, sus locos desatinos escribieron, y con nombre de aquel que aborrecían, impresos por el mundo los envían.

[26] _El original_, del.

BARRILDO

No soy de esa opinión.

LEONELO

El ignorante es justo que se vengue del letrado.

BARRILDO

Leonelo, la impresión es importante.

LEONELO

Sin ella muchos siglos se han pasado, y no vemos que en éste se levante un Jerónimo santo, un Agustino. ...[27].

[27] Falta un verso para la octava.

BARRILDO

Dejadlo y asentaos, que estáis mohino.

(_Salen_ JUAN ROJO _y otro labrador._)

JUAN ROJO

No hay en cuatro haciendas para un dote, si es que las vistas han de ser al uso; que el hombre que es curioso es bien que note que en esto el barrio y vulgo anda confuso.

LABRADOR

¿Qué hay del comendador? No os alborote.

JUAN ROJO

¡Cuál a Laurencia en ese campo puso!

LABRADOR

¿Quién fué cual él tan bárbaro y lascivo? Colgado le vea yo del aquel olivo.

(_Salen el_ COMENDADOR, ORTUÑO _y_ FLORES.)

COMENDADOR

Dios guarde la buena gente.

REGIDOR

¡Oh, señor!

COMENDADOR

Por vida mía, que se estén.

[ESTEBAN] ALCALDE

Vusiñoría, adonde suele se siente, que en pie estaremos muy bien.

COMENDADOR

Digo que se han de sentar.

ESTEBAN

De los buenos es honrar, que no es posible que den honra los que no la tienen.

COMENDADOR

Siéntense; hablaremos algo.

ESTEBAN

¿Vió vusiñoría el galgo?

COMENDADOR

Alcalde, espantados vienen esos criados de ver tan notable ligereza.

ESTEBAN

Es una extremada pieza. Pardiez, que puede correr [al][28] lado de un delincuente o de un cobarde en quistión[29].

[28] _El original_, a un.

[29] _Quistión_, cuestión, tormento.

COMENDADOR

Quisiera en esta ocasión que le hiciérades pariente[30] a una liebre que por pies por momentos se me va.

[30] _Hacer pariente_, juntar, reunir.

ESTEBAN

Sí haré, par Dios. ¿Dónde está?

COMENDADOR

Allá vuestra hija es.

ESTEBAN

¡Mi hija!

COMENDADOR

Sí.

ESTEBAN

Pues ¿es buena para alcanzada de vos?

COMENDADOR

Reñilda, alcalde, por Dios.

ESTEBAN

¿Cómo?

COMENDADOR

Ha dado en darme pena. Mujer hay, y principal, de alguno que está en la plaza, que dió, a la primera traza, traza de verme.

ESTEBAN

Hizo mal; y vos, señor, no andáis bien en hablar tan libremente.

COMENDADOR

¡Oh, qué villano elocuente! ¡Ah, Flores!, haz que le den la _Política_, en que lea de Aristóteles.

ESTEBAN

Señor, debajo de vuestro honor vivir el pueblo desea. Mirad que en Fuente Ovejuna hay gente muy principal.

LEONELO

¿Vióse desvergüenza igual?

COMENDADOR

Pues ¿he dicho cosa alguna de que os pese, regidor?

REGIDOR

Lo que decís es injusto; no lo digáis, que no es justo que nos quitéis el honor.

COMENDADOR

¿Vosotros honor tenéis? ¡Qué freiles de Calatrava!

REGIDOR

Alguno acaso se alaba de la cruz que le ponéis, que no es de sangre tan limpia.

COMENDADOR

Y ¿ensucióla yo juntando la mía a la vuestra?

REGIDOR

Cuando que el mal más tiñe que alimpia.

COMENDADOR

De cualquier suerte que sea, vuestras mujeres se honran.

ESTEBAN

Esas palabras deshonran[31]; las o[t]ras[32], no hay quien las crea.

[31] _El original_, les honran.

[32] _El original_, obras.

COMENDADOR

¡Qué cansado villanaje! ¡Ah! Bien hayan las ciudades; que a hombres de calidades no hay quien sus gustos ataje; allá se precian casados que visiten sus mujeres.

ESTEBAN

No harán; que con esto quieres que vivamos descuidados. En las ciudades hay Dios, y más presto quien castiga.

COMENDADOR

Levantaos de aquí.

ESTEBAN

¿Que diga lo que escucháis por los dos?

COMENDADOR

Salí de la plaza luego; no quede ninguno aquí.

ESTEBAN

Ya nos vamos.

COMENDADOR

Pues no ansí.

FLORES

Que te reportes te ruego.

COMENDADOR

Querrían hacer corrillo los villanos en mi ausencia.

ORTUÑO

Ten un poco de paciencia.

COMENDADOR

De tanta me maravillo. Cada uno de por sí se vayan hasta sus casas.

LEONELO

¡Cielo! ¿Que por esto pasas?

ESTEBAN

Ya yo me voy por aquí.

(_Vanse._)

COMENDADOR

¿Qué os parece de esta gente?

ORTUÑO

No sabes disimular que no quiere[s][33] escuchar el disgusto que se siente.

[33] _El original_, quieren.

COMENDADOR

Estos ¿se igualan conmigo?

FLORES

Que no es aqueso igualarse.

COMENDADOR

Y el villano ¿ha de quedarse con ballesta y sin castigo?

FLORES

Anoche pensé que estaba a la puerta de Laurencia, y a otro, que su presencia y su capilla imitaba, de oreja a oreja le di un beneficio famoso.

COMENDADOR

¿Dónde estará aquel Frondoso?

FLORES

Dicen que anda por ahí.

COMENDADOR

¡Por ahí se atreve a andar hombre que matarme quiso!

FLORES

Como el ave sin aviso, o como el pez, viene a dar al reclamo o al anzuelo.

COMENDADOR

¡Que a un capitán cuya espada tiemblan Córdoba y Granada, un labrador, un mozuelo ponga una ballesta al pecho! El mundo se acaba, Flores.

FLORES

Como eso pueden amores.

ORTUÑO

Y pues que vive, sospecho que grande amistad le debes.

COMENDADOR

Yo he disimulado, Ortuño; que si no, de punta a puño, antes de dos horas breves, pasara todo el lugar; que hasta que llegue ocasión al freno de la razón hago la venganza estar.-- ¿Qué hay de Pascuala?

FLORES

Responde que anda agora por casarse.

COMENDADOR

¿Hasta allá quiere fiarse?...

FLORES

En fin, te remite donde te pagarán de contado.

COMENDADOR

¿Qué hay de Olalla?

ORTUÑO

Una graciosa respuesta.

COMENDADOR

Es moza briosa. ¿Cómo?

ORTUÑO Que su desposado anda tras ella estos días celoso de mis recados, y de que con tus criados a visitalla venías; pero que si se descuida, entrarás como primero.

COMENDADOR

¡Bueno, a fe de caballero! Pero el villanejo cuida...

ORTUÑO

Cuida, y anda por los aires.

COMENDADOR

¿Qué hay de Inés?

FLORES

¿Cuál?

COMENDADOR

La de Antón.

FLORES

Para cualquier ocasión ya ha ofrecido sus donaires.

Háblela por el corral, por donde has de entrar si quieres.

COMENDADOR

A las fáciles mujeres quiero bien y pago mal. Si éstas supiesen, ¡oh, Flores!, estimarse en lo que valen...

FLORES

No hay disgustos que se igualen a contrastar sus favores. Rendirse presto desdice de la esperanza del bien; mas hay mujeres también, porque el filósofo dice que apetecen a los hombres como la forma desea la materia; y que esto sea así, no hay de que te asombre.

COMENDADOR

Un hombre de amores loco huélgase que a su accidente se le rindan fácilmente, mas después las tiene en poco, y el camino de olvidar al hombre más obligado es haber poco costado lo que pudo desear.

(_Sale_ CIMBRANOS, _soldado._)

[CIMBRANOS], SOLDADO

¿Está aquí el comendador?

ORTUÑO

¿No le ves en tu presencia?

[CIMBRANOS], SOLDADO

¡Oh, gallardo Fernán Gómez! Trueca la verde montera en el blanco morrión y el gabán en armas nuevas, que el maestre de Santiago, y el conde de Cabra cercan a don Rodrigo Girón, por la castellana reina, en Ciudad Real; de suerte que no es mucho que se pierda lo que en Calatrava sabes que tanta sangre le cuesta. Ya divisan con las luces, desde las altas almenas, los castillos y leones y barras aragonesas. Y aunque el rey de Portugal honrar a Girón quisiera, no hará poco en que el maestre a Almagro con vida vuelva. Ponte a caballo, señor; que sólo con que te vean, se volverán a Castilla.

COMENDADOR

No prosigas; tente, espera.-- Haz, Ortuño, que en la plaza toquen luego una trompeta. ¿Qué soldados tengo aquí?

ORTUÑO

Pienso que tienes cincuenta.

COMENDADOR

Pónganse a caballo todos.

[CIMBRANOS], SOLDADO

Si no caminas apriesa, Ciudad Real es del rey.

COMENDADOR

No hayas miedo que lo sea.

[_Vanse._]

(_Salen_ MENGO _y_ LAURENCIA _y_ PASCUALA, _huyendo._)

PASCUALA

No te apartes de nosotras.

MENGO

Pues ¿a qué tenéis temor?

LAURENCIA

Mengo, a la villa es mejor que vamos unas con otras (pues que no hay hombre ninguno), por que no demos con él.

MENGO

¡Que este demonio cruel nos sea tan importuno!

LAURENCIA

No nos deja a sol ni a sombra.

MENGO

¡Oh! Rayo del cielo baje, que sus locuras ataje.

LAURENCIA

Sangrienta fiera le nombra; arsénico y pestilencia del lugar.

MENGO

Hanme contado que Frondoso, aquí en el prado, para librarte, Laurencia, le puso al pecho una jara.

LAURENCIA

Los hombres aborrecía, Mengo; mas desde aquel día los miro con otra cara. ¡Gran valor tuvo Frondoso! Pienso que le ha de costar la vida.

MENGO

Que del lugar se vaya, será forzoso.

LAURENCIA

Aunque ya le quiero bien, eso mismo le aconsejo; mas recibe mi consejo con ira, rabia y desdén; y jura el comendador que le ha de colgar de un pie.

PASCUALA

¡Mal garrotillo le dé!

MENGO

Mala pedrada es mejor. ¡Voto al sol, si le tirara con la que llevo al apero, que al sonar el crujidero, al casco se la encajara! No fué Sábalo, el romano, tan vicioso por jamás.

LAURENCIA

Heliogábalo dirás, más que una fiera inhumano.

MENGO

Pero Galván, o quién fué, que yo no entiendo de historia; mas su cativa memoria vencida de éste se ve. ¿Hay hombre en naturaleza como Fernán Gómez?

PASCUALA

No; que parece que le dió de una tigre la aspereza.

(_Sale_ JACINTA.)

JACINTA

Dadme socorro, por Dios, si la amistad os obliga.

LAURENCIA

¿Qué es esto, Jacinta amiga?

PASCUALA

Tuyas lo somos las dos.

JACINTA

Del comendador criados, que van a Ciudad Real, más de infamia natural que de noble acero armados, me quieren llevar a él.

LAURENCIA

Pues Jacinta, Dios te libre; que cuando contigo es libre, conmigo será cruel. (_Vase._)

PASCUALA

Jacinta, yo no soy hombre que te puedo defender. (_Vase._)

MENGO

Yo sí lo tengo de ser, porque tengo el ser y el nombre. Llégate, Jacinta, a mí.

JACINTA

¿Tienes armas?

MENGO

Las primeras del mundo.

JACINTA

¡Oh, si las tuvieras!

MENGO

Piedras hay, Jacinta, aquí.

(_Salen_ FLORES _y_ ORTUÑO.)

FLORES

¿Por los pies pensabas irte?

JACINTA

Mengo, ¡muerta soy!

MENGO

Señores... ¡A estos pobres labradores!...

ORTUÑO

Pues ¿tú quieres persuadirte a defender la mujer?

MENGO

Con los ruegos la defiendo; que soy su deudo y pretendo guardalla, si puede ser.

FLORES

Quitalde luego la vida.

MENGO

¡Voto al sol, si me emberrincho, y el cáñamo me descincho, que la llevéis bien vendida!

(_Salen el_ COMENDADOR _y_ CIMBRANOS.)

COMENDADOR

¿Qué es eso? ¡A cosas tan viles me habéis de hacer apear!

FLORES

Gente de este vil lugar (que ya es razón que aniquiles, pues en nada te da gusto) a nuestras armas se atreve.

MENGO

Señor, si piedad os mueve de suceso tan injusto, castigad estos soldados, que con vuestro nombre agora roban una labradora [a] esposo y padres honrados; y dadme licencia a mí que se la pueda llevar.

COMENDADOR

Licencia les quiero dar... para vengarse de ti. Suelta la honda.

MENGO

¡Señor!...

COMENDADOR

Flores, Ortuño, Cimbranos, con ella le atad las manos.

MENGO

¿Así volvéis por su honor?

COMENDADOR

¿Qué piensan Fuente Ovejuna y sus villanos de mí?

MENGO

Señor, ¿en qué os ofendí, ni el pueblo en cosa ninguna?

FLORES

¿Ha de morir?

COMENDADOR

No ensuciéis las armas, que habéis de honrar en otro mejor lugar.

ORTUÑO

¿Qué mandas?

COMENDADOR

Que lo azotéis. Llevadle, y en ese roble le atad y le desnudad, y con las riendas...

MENGO

¡Piedad! ¡Piedad, pues sois hombre noble!

COMENDADOR

Azotalde hasta que salten los hierros de las correas.

MENGO

¡Cielos! ¿A hazañas tan feas queréis que castigos falten?

(_Vanse._)

COMENDADOR

Tú, villana, ¿por qué huyes? ¿Es mejor un labrador que un hombre de mi valor?

JACINTA

¡Harto bien me restituyes el honor que me han quitado en llevarme para ti!

COMENDADOR

¿En quererte llevar?

JACINTA

Sí; porque tengo un padre honrado, que si en alto nacimiento no te iguala, en las costumbres te vence.

COMENDADOR

Las pesadumbres y el villano atrevimiento no tiemplan bien un airado. Tira por ahí.

JACINTA

¿Con quién?

COMENDADOR

Conmigo.

JACINTA

Míralo bien.

COMENDADOR

Para tu mal lo he mirado. Ya no mía, del bagaje del ejército has de ser.

JACINTA

No tiene el mundo poder para hacerme, viva, ultraje.

COMENDADOR

Ea, villana, camina.

JACINTA

¡Piedad, señor!

COMENDADOR

No hay piedad.

JACINTA

Apelo de tu crueldad a la justicia divina.

(_Llévanla y vanse, y salen_ LAURENCIA _y_ FRONDOSO.)

LAURENCIA

¿Cómo así a venir te atreves, sin temer tu daño?

FRONDOSO

Ha sido dar testimonio cumplido de la afición que me debes. Desde aquel recuesto vi salir al comendador, y fiado en tu valor, todo mi temor perdí. Vaya donde no le vean volver.

LAURENCIA

Tente en maldecir, porque suele más vivir al que la muerte desean.

FRONDOSO

Si es eso, viva mil años, y así se hará todo bien, pues deseándole bien estarán ciertos sus daños. Laurencia, deseo saber si vive en ti mi cuidado, y si mi lealtad ha hallado el puerto de merecer. Mira que toda la villa ya para en uno nos tiene; y de cómo a ser no viene, la villa se maravilla. Los desdeñosos extremos deja, y responde no o sí.

LAURENCIA

Pues a la villa y a ti respondo que lo seremos.

FRONDOSO

Deja que tus plantas bese por la merced recibida, pues el cobrar nueva vida por ella es bien que confiese.

LAURENCIA

De cumplimientos acorta; y para que mejor cuadre, habla, Frondoso, a mi padre, pues es lo que más importa, que allí viene con mi tío; y fía que ha de tener ser, Frondoso, tu mujer, buen suceso.

FRONDOSO

En Dios confío.

(_Escóndese._)

(_Salen_ ESTEBAN, _alcalde_, _y el_ REGIDOR.)

[ESTEBAN], ALCALDE

Fué su término de modo, que la plaza alborotó: en efeto, procedió muy descomedido en todo. No hay a quien admiración sus demasías no den; la pobre Jacinta es quien pierde por su sinrazón.

REGIDOR

Ya [a] los Católicos Reyes, que este nombre les dan ya, presto España les dará la obediencia de sus leyes. Ya sobre Ciudad Real, contra el Girón que la tiene, Santiago a caballo viene por capitán general. Pésame; que era Jacinta doncella de buena pro.

[ESTEBAN], ALCALDE

Luego a Mengo le azotó.

REGIDOR

No hay negra bayeta o tinta como sus carnes están.

[ESTEBAN], ALCALDE

Callad; que me siento arder, viendo su mal proceder, y el mal nombre que le dan. Yo ¿para qué traigo aquí este palo sin provecho?

REGIDOR

Si sus criados lo han hecho, ¿de qué os afligís ansí?

[ESTEBAN], ALCALDE

¿Queréis más, que me contaron que a la de Pedro Redondo un día, que en lo más hondo de este valle la encontraron, después de sus insolencias, a sus criados la dió?

REGIDOR

Aquí hay gente: ¿quién es?

FRONDOSO

Yo, que espero vuestras licencias.

REGIDOR

Para mi casa, Frondoso, licencia no es menester; debes a tu padre el ser, y a mí otro ser amoroso. Hete criado, y te quiero como a hijo.

FRONDOSO

Pues señor, fiado en aquese amor, de ti una merced espero. Ya sabes de quién soy hijo.

ESTEBAN

¿Hate agraviado ese loco de Fernán Gómez?

FRONDOSO

No poco.

ESTEBAN

El corazón me lo dijo.

FRONDOSO

Pues señor, con el seguro del amor que habéis mostrado, de Laurencia enamorado, el ser su esposo procuro. Perdona si en el pedir mi lengua se ha adelantado; que he sido en decirlo osado, como otro lo ha de decir.

ESTEBAN

Vienes, Frondoso, a ocasión que me alargarás la vida por la cosa más temida que siente mi corazón. Agradezco, hijo, al cielo que así vuelvas por mi honor, y agradézcole a tu amor la limpieza de tu celo. Mas como es justo, es razón dar cuenta a tu padre de esto; sólo digo que estoy presto, en sabiendo su intención; que yo dichoso me hallo en que aqueso llegue a ser.

REGIDOR

De la moza el parecer tomad antes de acetallo.

[ESTEBAN], ALCALDE

No tengáis de eso cuidado, que ya el caso está dispuesto: antes de venir a esto, entre ellos se ha concertado. --En el dote, si advertís, se puede agora tratar; que por bien os pienso dar algunos maravedís.

FRONDOSO

Yo dote no he menester; de eso no hay que entristeceros

REGIDOR

Pues que no la pide en cueros lo podéis agradecer.

ESTEBAN

Tomaré el parecer de ella; si os parece, será bien.

FRONDOSO

Justo es; que no hace bien quien los gustos atropella.

ESTEBAN

¡Hija! ¡Laurencia!...

LAURENCIA

Señor...

ESTEBAN

Mirad si digo bien yo. ¡Ved qué presto respondió!-- Hija Laurencia, mi amor, a preguntarte ha venido (apártate aquí) si es bien que a Gila, tu amiga, den a Frondoso por marido, que es un honrado zagal, si le hay en Fuente Ovejuna...

LAURENCIA

¿Gila se casa?

ESTEBAN

Y si alguna le merece y es su igual.

LAURENCIA

Yo digo, señor, que sí.

ESTEBAN

Sí; mas yo digo que es fea y que harto mejor se emplea Frondoso, Laurencia, en ti.

LAURENCIA

¿Aun no se te han olvidado los donaires con la edad?

ESTEBAN

¿Quiéresle tú?

LAURENCIA

Voluntad le he tenido y le he cobrado, pero por lo que tú sabes...

ESTEBAN

¿Quieres tú que diga sí?

LAURENCIA

Dilo tú, señor, por mí.

ESTEBAN

¿Yo? Pues tengo yo las llaves, hecho está.--Ven, buscaremos a mi compadre en la plaza.

REGIDOR

Vamos.

ESTEBAN

Hijo, y en la traza del dote, ¿qué le diremos? Que yo bien te puedo dar cuatro mil maravedís.

FRONDOSO

Señor, ¿eso me decís? Mi honor queréis agraviar.

ESTEBAN

Anda, hijo; que eso es cosa que pasa en un día: que si no hay dote, a fe mía que se echa menos después.

(_Vanse, y quedan_ FRONDOSO _y_ LAURENCIA.)

LAURENCIA

Di, Frondoso, ¿estás contento?

FRONDOSO

¡Cómo si lo estoy! ¡Es poco, pues que no me vuelvo loco de gozo, del bien que siento! Risa vierte el corazón por los ojos de alegría, viéndote, Laurencia mía, en tal dulce posesión.

[_Vanse._]

(_Salen el_ MAESTRE, _el_ COMENDADOR, FLORES _y_ ORTUÑO.)

COMENDADOR

Huye, señor, que no hay otro remedio.

MAESTRE

La flaqueza del muro lo ha causado, y el poderoso ejército enemigo.

COMENDADOR

Sangre les cuesta y infinitas vidas.

MAESTRE

Y no se alabarán que en sus despojos pondrán nuestro pendón de Calatrava, que a honrar su empresa y los demás bastaba.

COMENDADOR

Tus desinios, Girón, quedan perdidos.

MAESTRE

¿Qué puedo hacer, si la fortuna, ciega, a quien hoy levantó mañana humilla?

(_Dentro._)

¡Vitoria por los reyes de Castilla!

MAESTRE

Ya coronan de luces las almenas, y las ventanas de las torres altas entoldan con pendones vitoriosos.

COMENDADOR

Bien pudieran, de sangre que les cuesta. A fe que es más tragedia que no fiesta.

MAESTRE

Yo vuelvo a Calatrava, Fernán Gómez.

COMENDADOR

Y yo a Fuente Ovejuna, mientras tratas o seguir esta parte de tus deudos, o reducir la tuya al Rey Católico.

MAESTRE

Yo te diré por cartas lo que intento.

COMENDADOR

El tiempo ha de enseñarte.

MAESTRE

¡Ah, pocos años, sujetos al rigor de sus engaños!

(_Sale la boda._ MÚSICOS, MENGO, FRONDOSO, LAURENCIA, PASCUALA, BARRILDO, ESTEBAN _y_ ALCALDE [JUAN ROJO].)

MÚSICOS

¡Vivan muchos años los desposados! ¡Vivan muchos años!

MENGO

A fe, que no os ha costado mucho trabajo el cantar.

BARRILDO

Supiéraslo tú trovar mejor que él está trovado.

FRONDOSO

Mejor entiende de azotes Mengo que de versos ya.

MENGO

Alguno en el valle está, para que no te alborotes, a quien el comendador...

BARRILDO

No lo digas, por tu vida; que este bárbaro homicida a todos quita el honor.

MENGO

Que me azotasen a mí cien soldados aquel día... sola una honda tenía; ...[34] pero que le hayan echado una melecina[35] a un hombre, que, aunque no diré su nombre, todos saben que es honrado, llena de tinta y de chinas, ¿cómo se puede sufrir?

[34] Falta un verso.

[35] _Melecina_, lavativa.

BARRILDO

Haríalo por reír.

MENGO

No hay risa con melecinas; que aunque es cosa saludable... yo me quiero morir luego.

FRONDOSO

Vaya la copla, te ruego, si es la copla razonable.

MENGO

Vivan muchos años juntos los novios, ruego a los cielos, y por envidia ni celos ni riñan ni anden en puntos. Lleven a entrambos difuntos, de puro vivir cansados. ¡Vivan muchos años!

[FRONDOSO][36]

¡Maldiga el cielo el poeta, que tal coplón arrojó!

[36] _El original_, Mengo.

BARRILDO

Fué muy presto...

MENGO

Pienso yo una cosa de esta seta[37]. ¿No habéis visto un buñolero, en el aceite abrasando pedazos de masa echando hasta llenarse el caldero? ¿Que unos le salen hinchados, otros tuertos y mal hechos, ya zurdos y ya derechos, ya fritos y ya quemados? Pues así imagino yo un poeta componiendo, la materia previniendo que es quien la masa le dió. Va arrojando verso aprisa al caldero del papel, confiado en que la miel cubrirá la burla y risa. Mas poniéndolo en el pecho, apenas hay quien los tome; tanto que sólo los come el mismo que los ha hecho.

[37] _Seta_, secta.

BARRILDO

Déjate ya de locuras; deja los novios hablar.

LAURENCIA

Las manos nos da a besar.

JUAN [ROJO]

Hija, ¿mi mano procuras? Pídela a tu padre luego para ti y para Frondoso.

ESTEBAN

Rojo, a ella y a su esposo que se la dé el cielo ruego, con su larga bendición.

FRONDOSO

Los dos a los dos la echad.

JUAN [ROJO]

Ea, tañed y cantad, pues que para en uno son.

MÚSICOS

Al val de Fuente Ovejuna la niña en cabellos baja; el caballero la sigue de la Cruz de Calatrava. Entre las ramas se esconde, de vergonzosa y turbada; fingiendo que no le ha visto, pone delante las ramas. «¿Para qué te ascondes, niña gallarda? Que mis linces deseos paredes pasan.» Acercóse él caballero, y ella, confusa y turbada, hacer quiso celosías de las intrincadas ramas; mas como quien tiene amor los mares y las montañas atraviesa fácilmente, la dice tales palabras: «¿Para qué te ascondes, niña gallarda? Que mis linces deseos paredes pasan.»

(_Salen el_ COMENDADOR, FLORES, ORTUÑO _y_ CIMBRANOS.)

COMENDADOR

Estése la boda queda, y no se alborote nadie.

JUAN [ROJO]

No es juego aqueste, señor, y basta que tú lo mandes. ¿Quieres lugar? ¿Cómo vienes con tu belicoso alarde? ¿Venciste? Mas ¿qué pregunto?

FRONDOSO

¡Muerto soy! ¡Cielos, libradme!

LAURENCIA

Huye por aquí, Frondoso.

COMENDADOR

Eso no; prendelde, atalde.

JUAN [ROJO]

Date, muchacho, a prisión.

FRONDOSO

Pues ¿quieres tú que me maten?

JUAN [ROJO]

¿Por qué?

COMENDADOR

No soy hombre yo que mato sin culpa a nadie; que si lo fuera, le hubieran pasado de parte a parte esos soldados que traigo. Llevarle mando a la cárcel, donde la culpa que tiene sentencie su mismo padre.

PASCUALA

Señor, mirad que se casa.

COMENDADOR

¿Qué me obliga a que se case? ¿No hay otra gente en el pueblo?

PASCUALA

Si os ofendió perdonadle, por ser vos quien sois.

COMENDADOR

No es cosa, Pascuala, en que yo soy parte. Es esto contra el maestre Téllez Girón, que Dios guarde; es contra toda su orden, es su honor, y es importante para el ejemplo, el castigo; que habrá otro día quien trate de alzar pendón contra él, pues ya sabéis que una tarde al comendador mayor (¡qué vasallos tan leales!) puso una ballesta al pecho.

ESTEBAN

Supuesto que el disculparle ya puede tocar a un suegro, no es mucho que en causas tales se descomponga con vos un hombre, en efecto, amante; porque si vos pretendéis su propia mujer quitarle, ¿qué mucho que la defienda?

COMENDADOR

Majadero sois, alcalde.

ESTEBAN

Por vuestra virtud, señor.

COMENDADOR

Nunca yo quise quitarle su mujer, pues no lo era.

ESTEBAN

Si quisistes...--Y esto baste; que reyes hay en Castilla que nuevas órdenes hacen con que desórdenes quitan. Y harán mal cuando descansen de las guerras, en sufrir en sus villas y lugares a hombres tan poderosos por traer cruces tan grandes; póngasela el rey al pecho, que para pechos reales es esa insignia y no más.

COMENDADOR

¡Hola! La vara quitalde.

ESTEBAN

Tomad, señor, norabuena.

COMENDADOR

Pues con ella quiero dalle, como a caballo brioso.

ESTEBAN

Por señor os sufro. Dadme.

PASCUALA

¡A un viejo de palos das!

LAURENCIA

Si le das porque es mi padre, ¿qué vengas en él de mí?

COMENDADOR

Llevalda, y haced que guarden su persona diez soldados.

(_Vase él y los suyos._)

ESTEBAN

Justicia del cielo baje. (_Vase._)

PASCUALA

Volvióse en luto la boda. (_Vase._)

BARRILDO

¿No hay aquí un hombre que hable?

MENGO

Yo tengo ya mis azotes, que aun se ven los cardenales sin que un hombre vaya a Roma. Prueben otros a enojarle.

JUAN [ROJO]

Hablemos todos.

MENGO

Señores, aquí todo el mundo calle. Como ruedas de salmón me puso los atabales.

ACTO TERCERO DE FUENTE OVEJUNA

ACTO TERCERO DE FUENTE OVEJUNA

(_Salen_ ESTEBAN, ALONSO _y_ BARRILDO.)

ESTEBAN

¿No han venido a la junta?

BARRILDO

No han venido.

ESTEBAN

Pues más apriesa nuestro daño corre.

BARRILDO

Ya está lo más del pueblo prevenido.

ESTEBAN

Frondoso con prisiones en la torre, y mi hija Laurencia en tanto aprieto, si la piedad de Dios no los socorre...

(_Salen_ JUAN ROJO _y el_ REGIDOR.)

JUAN

¿De qué dais voces, cuando importa tanto a nuestro bien, Esteban, el secreto?

ESTEBAN

Que doy tan pocas es mayor espanto.

(_Sale_ MENGO.)

MENGO

También vengo yo a hallarme en esta junta.

ESTEBAN

Un hombre cuyas canas baña el llanto, labradores honrados, os pregunta qué obsequias[38] debe hacer toda esa gente a su patria sin honra, ya perdida. Y si se llaman honras justamente, ¿cómo se harán, si no hay entre nosotros hombre a quien este bárbaro no afrente? Respondedme: ¿hay alguno de vosotros que no esté lastimado en honra y vida? ¿No os lamentáis los unos de los otros? Pues si ya la tenéis todos perdida, ¿a qué aguardáis? ¿Qué desventura es ésta?

[38] _Obsequias_, funerales.

JUAN

La mayor que en el mundo fué sufrida. Mas pues ya se publica y manifiesta que en paz tienen los reyes a Castilla y su venida a Córdoba se apresta, vayan dos regidores a la villa, y echándose a sus pies pidan remedio.

BARRILDO

En tanto que Fernando, aquel que humilla a tantos enemigos, otro medio será mejor[39], pues no podrá, ocupado, hacemos bien, con tanta guerra en medio.

[39] La frase está construída como si hubiese escrito el autor: «En tanto que Fernando humilla a tantos enemigos.»

REGIDOR

Si mi voto de vos fuera escuchado, desamparar la villa doy por voto.

JUAN

¿Cómo es posible en tiempo limitado?

MENGO

A la fe, que si entiendo el alboroto, que ha de costar la junta alguna vida.

REGIDOR

Ya, todo el árbol de paciencia roto, corre la nave de temor perdida. La hija quitan con tan gran fiereza a un hombre honrado, de quien es regida la patria en que vivís, y en la cabeza la vara quiebran tan injustamente. ¿Qué esclavo se trató con más bajeza?

JUAN

¿Qué es lo que quieres tú que el pueblo intente?

REGIDOR

Morir, o dar la muerte a los tiranos, pues somos muchos, y ellos poca gente.

BARRILDO

¡Contra el señor las armas en las manos!

ESTEBAN

El rey solo es señor después del cielo, y no bárbaros hombres inhumanos. Si Dios ayuda nuestro justo celo, ¿qué nos ha de costar?

MENGO

Mirad, señores que vais en estas cosas con recelo. Puesto que[40] por los simples labradores estoy aquí, que más injurias pasan, más cuerdo represento sus temores.

[40] Aunque.

JUAN

Si nuestras desventuras se compasan, para perder las vidas, qué aguardamos Las casas y las viñas nos abrasan: tiranos son; a la venganza vamos.

(_Sale_ LAURENCIA, _desmelenada._)

LAURENCIA

Dejadme entrar, que bien puedo en consejo de los hombres; que bien puede una mujer, si no a dar voto a dar voces.
¿Conocéisme?

ESTEBAN

¡Santo cielo! ¿No es mi hija?

JUAN

¿No conoces A Laurencia?

LAURENCIA

Vengo tal, que mi diferencia os pone en contingencia quién soy.

ESTEBAN

¡Hija mía!

LAURENCIA

No me nombres tu hija.

ESTEBAN

¿Por qué, mis ojos? ¿Por qué?

LAURENCIA

Por muchas razones, y sean las principales, porque dejas que me roben tiranos sin que me vengues, traidores sin que me cobres. Aun no era yo de Frondoso, para que digas que tome, como marido, venganza; que aquí por tu cuenta corre; que en tanto que de las bodas no haya llegado la noche, del padre, y no del marido, la obligación presupone; que en tanto que no me entregan una joya, aunque la compren, no ha de correr por mi cuenta las guardas ni los ladrones. Llevóme de vuestros ojos a su casa Fernán Gómez: la oveja al lobo dejáis, como cobardes pastores. ¿Qué dagas no vi en mi pecho? ¡Qué desatinos enormes, qué palabras, qué amenazas, y qué delitos atroces, por rendir mi castidad a sus apetitos torpes! Mis cabellos, ¿no lo dicen? ¿No se ven aquí los golpes, de la sangre y las señales? ¿Vosotros sois hombres nobles? ¿Vosotros padres y deudos? ¿Vosotros, que no se os rompen las entrañas de dolor, de verme en tantos dolores? Ovejas sois, bien lo dice de Fuente Ovejuna el nombre. Dadme unas armas a mí, pues sois piedras, pues sois bronces, pues sois jaspes, pues sois tigres... --Tigres no, porque feroces siguen quien roba sus hijos, matando los cazadores antes que entren por el mar y por sus ondas se arrojen. Liebres cobardes nacistes; bárbaros sois, no españoles. Gallinas, ¡vuestras mujeres sufrís que otros hombres gocen! Poneos ruecas en la cinta. ¿Para qué os ceñís estoques? ¡Vive Dios, que he de trazar que solas mujeres cobren la honra de estos tiranos, la sangre de estos traidores, y que os han de tirar piedras, hilanderas, maricones, amujerados, cobardes, y que mañana os adornen nuestras tocas y basquiñas, solimanes y colores! A Frondoso quiere ya, sin sentencia, sin pregones, colgar el comendador del almena de una torre; de todos hará lo mismo; y yo me huelgo, medio-hombres, por que quede sin mujeres esta villa honrada, y torne aquel siglo de amazonas, eterno espanto del orbe.

ESTEBAN

Yo, hija, no soy de aquellos que permiten que los nombres con esos títulos viles. Iré solo, si se pone todo el mundo contra mí.

JUAN

Y yo, por más que me asombre la grandeza del contrario.

REGIDOR

Muramos todos.

BARRILDO

Descoge un lienzo al viento en un palo, y mueran estos inormes[41].

[41] _Inorme_, forma anticuada de «enorme».

JUAN

¿Qué orden pensáis tener?

MENGO

Ir a matarle sin orden. Juntad el pueblo a una voz; que todos están conformes en que los tiranos mueran.

ESTEBAN

Tomad espadas, lanzones, ballestas, chuzos y palos.

MENGO

¡Los reyes nuestros señores vivan!

TODOS

¡Vivan muchos años!

MENGO

¡Mueran tiranos traidores!

TODOS

¡Traidores tiranos mueran!

(_Vanse todos._)

LAURENCIA

Caminad, que el cielo os oye. --¡Ah mujeres de la villa! ¡Acudid, por que se cobre vuestro honor, acudid todas!

(_Salen_ PASCUALA, JACINTA _y otras mujeres_)

PASCUALA

¿Qué es esto? ¿De qué das voces?

LAURENCIA

¿No veis cómo todos van a matar a Fernán Gómez, y hombres, mozos y muchachos, furiosos, al hecho corren? ¿Será bien que solos ellos de esta hazaña el honor gocen, pues no son de las mujeres sus agravios los menores?

JACINTA

Di, pues, ¿qué es lo que pretendes?

LAURENCIA

Que puestas todas en orden, acometamos a un hecho que dé espanto a todo el orbe. Jacinta, tu grande agravio, que sea cabo[42]; responde de una escuadra de mujeres.

[42] _Cabo_, el jefe.

JACINTA

No son los tuyos menores.

LAURENCIA

Pascuala, alférez serás.

PASCUALA

Pues déjame que enarbole en un asta la bandera: verás si merezco el nombre.

LAURENCIA

No hay espacio para eso, pues la dicha nos socorre: bien nos basta que llevemos nuestras tocas por pendones.

PASCUALA

Nombremos un capitán.

LAURENCIA

Eso no.

PASCUALA

¿Por qué?

LAURENCIA

Que adonde asiste mi gran valor, no hay Cides ni Rodamontes.

(_Vanse._)

(_Sale_ FRONDOSO, _atadas las manos_; FLORES, ORTUÑO, CIMBRANOS _y el_ COMENDADOR.)

COMENDADOR

De ese cordel que de las manos sobra quiero que le colguéis, por mayor pena.

FRONDOSO

¡Qué nombre, gran señor, tu sangre cobra!

COMENDADOR

Colgadle luego en la primera almena.

FRONDOSO

Nunca fué mi intención poner por obra tu muerte entonces.

FLORES

Grande ruido suena.

(_Ruido suene._)

COMENDADOR

¿Ruido?

FLORES

Y de manera que interrumpen tu justicia, señor.

ORTUÑO

Las puertas rompen.

(_Ruido._)

COMENDADOR

¡La puerta de mi casa, y siendo casa de la encomienda!

FLORES

El pueblo junto viene.

JUAN (_Dentro._)

Rompe, derriba, hunde, quema, abrasa.

ORTUÑO

Un popular motín mal se detiene.

COMENDADOR

¡El pueblo contra mí!

FLORES

La furia pasa tan adelante, que las puertas tiene echadas por la tierra.

COMENDADOR

Desatalde. Templa, Frondoso, ese villano alcalde.

FRONDOSO

Yo voy, señor; que amor les ha movido.

(_Vase._)

MENGO (_Dentro._)

¡Vivan Fernando y Isabel, y mueran los traidores!

FLORES

Señor, por Dios te pido que no te hallen aquí.

COMENDADOR

Si perseveran, este aposento es fuerte y defendido. Ellos se volverán.

FLORES

Cuando se alteran los pueblos agraviados, y resuelven, nunca sin sangre o sin venganza vuelven.

COMENDADOR

En esta puerta, así como rastrillo, su furor con las armas defendamos.

FRONDOSO (_Dentro._)

¡Viva Fuente Ovejuna!

COMENDADOR

¡Qué caudillo! Estoy porque a su furia acometamos.

FLORES

De la tuya, señor, me maravillo.

ESTEBAN

Ya el tirano y los cómplices miramos. ¡Fuente Ovejuna, y los tiranos mueran!

(_Salen todos._)

COMENDADOR

Pueblo, esperad.

TODOS

Agravios nunca esperan.

COMENDADOR

Decídmelos a mí, que iré pagando a fe de caballero esos errores.

TODOS

¡Fuente Ovejuna! ¡Viva el rey Fernando! ¡Mueran malos cristianos y traidores!

COMENDADOR

¿No me queréis oír? Yo estoy hablando; yo soy vuestro señor.

TODOS

Nuestros señores son los Reyes Católicos.

COMENDADOR

Espera.

TODOS

¡Fuente Ovejuna, y Fernán Gómez muera!

(_Vanse, y salen las mujeres armadas._)

LAURENCIA

Parad en este puesto de esperanzas soldados atrevidos, no mujeres.

PASCUALA

¿Lo[s] que mujeres son en las venganzas, en él beban su sangre es bien que esperes?

JACINTA

Su cuerpo recojamos en las lanzas.

PASCUALA

Todas son de esos mismos pareceres.

ESTEBAN (_Dentro._)

¡Muere, traidor comendador!

COMENDADOR

Ya muero. ¡Piedad, Señor, que en tu clemencia espero!

BARRILDO (_Dentro._)

Aquí está Flores.

MENGO

Dale a ese bellaco; que ese fué el que me dió dos mil azotes.

FRONDOSO (_Dentro._)

No me vengo si el alma no le saco.

LAURENCIA

No excusamos entrar.

PASCUALA

No te alborotes. Bien es guardar la puerta.

BARRILDO (_Dentro._)

No me aplaco. ¡Con lágrimas agora, marquesotes!

LAURENCIA

Pascuala, yo entro dentro; que la espada no ha de estar tan sujeta ni envainada.

(_Vase._)

BARRILDO [_Dentro._]

Aquí está Ortuño.

FRONDOSO [_Dentro._]

Córtale la cara.

(_Sale_ FLORES _huyendo_, _y_ MENGO _tras él._)

FLORES

¡Mengo, piedad!, que no soy yo el culpado.

MENGO

Cuando ser alcahuete no bastara, bastaba haberme el pícaro azotado.

PASCUALA

Dánoslo a las mujeres, Mengo, para... Acaba por tu vida.

MENGO

Ya está dado; que no le quiero yo mayor castigo.

PASCUALA

Vengaré tus azotes.

MENGO

Eso digo.

JACINTA

¡Ea, muera el traidor!

FLORES

¡Entre mujeres!

JACINTA

¿No le viene muy ancho?

PASCUALA

¿Aqueso lloras?

JACINTA

Muere, concertador de sus placeres.

PASCUALA

¡Ea, muera el traidor!

FLORES

¡Piedad, señoras!

(_Sale_ ORTUÑO _huyendo de_ LAURENCIA.)

ORTUÑO

Mira que no soy yo...

LAURENCIA

Ya sé quién eres.-- Entrad, teñid las armas vencedoras en estos viles.

PASCUALA

Moriré matando.

TODAS

¡Fuente Ovejuna, y viva el rey Fernando!

(_Vanse, y salen el_ REY DON FERNANDO _y la_ REINA DOÑA ISABEL, _y_ DON MANRIQUE, _maestre._)

MANRIQUE

De modo la prevención fué, que el efeto esperado llegamos a ver logrado con poca contradición. Hubo poca resistencia; y supuesto que la hubiera, sin duda ninguna fuera de poca o ninguna esencia. Queda el de Cabra ocupado en conservación del puesto, por si volviere dispuesto a él el contrario osado.

REY

Discreto el acuerdo fué, y que asista es conveniente, y reformando la gente, el paso tomado esté. Que con eso se asegura no podernos hacer mal Alfonso, que en Portugal tomar la fuerza procura. Y el de Cabra es bien que esté en ese sitio asistente, y como tan diligente, muestras de su valor dé; porque con esto asegura el daño que nos recela, y como fiel centinela, el bien del reino procura.

(_Sale_ FLORES, _herido._)

FLORES

Católico rey Fernando, a quien el cielo concede la corona de Castilla, como a varón excelente; oye la mayor crueldad que se ha visto entre las gentes desde donde nace el sol hasta donde se oscurece.

REY

Repórtate.

FLORES

Rey supremo, mis heridas no consienten dilatar el triste caso, por ser mi vida tan breve. De Fuente Ovejuna vengo, donde, con pecho inclemente, los vecinos de la villa a su señor dieron muerte. Muerto Fernán Gómez queda por sus súbditos aleves; que vasallos indignados con leve causa se atreven. El título de tirano le acumula todo el plebe, y a la fuerza de esta voz el hecho fiero acometen; y quebrantando su casa, no atendiendo a que se ofrece por la fe de caballero a que pagará a quien debe, no sólo no le escucharon, pero con furia impaciente rompen el cruzado pecho con mil heridas crueles, y por las altas ventanas le hacen que al suelo vuele, adonde en picas y espadas le recogen las mujeres. Llévanle a una casa muerto, y, a porfía, quien más puede mesa su barba y cabello y apriesa su rostro hieren. En efeto fué la furia tan grande que en ellos crece, que las mayores tajadas las orejas a ser vienen. Sus armas borran con picas y a voces dicen que quieren tus reales armas fijar, porque aquéllas les ofenden. Saqueáronle la casa, cual si de enemigos fuese, y gozosos entre todos han repartido sus bienes. Lo dicho he visto escondido, porque mi infelice suerte en tal trance no permite que mi vida se perdiese; y así estuve todo el día hasta que la noche viene, y salir pude escondido para que cuenta te diese. Haz, señor, pues eres justo, que la justa pena lleven de tan riguroso caso los bárbaros delincuentes: mira que su sangre a voces pide que tu rigor prueben.

REY

Estar puedes confiado que sin castigo no queden. El triste suceso ha sido tal, que admirado me tiene, y que vaya luego un juez que lo averigüe conviene, y castigue a los culpados para ejemplo de las gentes. Vaya un capitán con él, por que seguridad lleve; que tan grande atrevimiento castigo ejemplar requiere; y curad a este soldado de las heridas que tiene.

(_Vanse, y salen los labradores y labradoras, con la cabeza de Fernán Gómez en una lanza._)

MÚSICOS

¡Muchos años vivan Isabel y Fernando, y mueran los tiranos!

BARRILDO

Diga su copla Frondoso.

FRONDOSO

Ya va mi copla a la fe; si le faltare algún pie, enmiéndelo el más curioso. «¡Vivan la bella Isabel, pues que para en uno son, él con ella, ella con él! A los cielos San Miguel lleve a los dos de las manos. ¡Vivan muchos años, y mueran los tiranos!»

LAURENCIA

Diga Barrildo.

BARRILDO

Ya va; que a fe que la he pensado.

PASCUALA

Si la dices con cuidado, buena y rebuena será.

BARRILDO

«¡Vivan los reyes famosos muchos años, pues que tienen la vitoria, y a ser vienen nuestros dueños venturosos! Salgan siempre vitoriosos de gigantes y de enanos, y ¡mueran los tiranos!»

MÚSICOS

¡Muchos años vivan!, etc.

LAURENCIA

Diga Mengo.

FRONDOSO

Mengo diga.

MENGO

Yo soy poeta donado.

PASCUALA

Mejor dirás lastimado el envés de la barriga.

MENGO

«Una mañana en domingo me mandó azotar aquél, de manera que el rabel daba espantoso respingo; pero agora que los pringo, ¡vivan los reyes cristiánigos, y mueran los tiránigos!»

MÚSICA

¡Vivan muchos años!

ESTEBAN

Quita la cabeza allá.

MENGO

Cara tiene de ahorcado.

(_Saca un escudo_ JUAN ROJO _con las armas [reales]_)

REGIDOR

Ya las armas han llegado.

ESTEBAN

Mostrá las armas acá.

JUAN

¿Adónde se han de poner?

REGIDOR

Aquí, en el ayuntamiento.

ESTEBAN

¡Bravo escudo!

BARRILDO

¡Qué contento!

FRONDOSO

Ya comienza a amanecer, con este sol, nuestro día.

ESTEBAN

¡Vivan Castilla y León, y las barras de Aragón, y muera la tiranía! Advertid, Fuente Ovejuna, a las palabras de un viejo; que el admitir su consejo no ha dañado vez ninguna. Los reyes han de querer averiguar este caso, y más tan cerca del paso y jornada que han de hacer. Concertaos todos a una en lo que habéis de decir.

FRONDOSO

¿Qué es tu consejo?

ESTEBAN

Morir diciendo _Fuente Ovejuna_, y a nadie saquen de aquí.

FRONDOSO

Es el camino derecho. Fuente Ovejuna lo ha hecho.

ESTEBAN

¿Queréis responder así?

TODOS

Sí.

ESTEBAN

Ahora[43], pues; yo quiero ser agora el pesquisidor, para ensayarnos mejor en lo que habemos de hacer. Sea Mengo el que esté puesto en el tormento.

[43] _El original_, agora.

MENGO

¿No hallaste otro más flaco?

ESTEBAN

¿Pensaste que era de veras?

MENGO

Di presto.

ESTEBAN

¿Quién mató al comendador?

MENGO

Fuente Ovejuna lo hizo.

ESTEBAN

Perro, ¿si te martirizo?

MENGO

Aunque me matéis, señor.

ESTEBAN

Confiesa, ladrón.

MENGO

Confieso.

ESTEBAN

Pues ¿quién fué?

MENGO

Fuente Ovejuna.

ESTEBAN

Dadle otra vuelta.

MENGO

Es ninguna.

ESTEBAN

Cagajón para el proceso.

(_Sale el_ REGIDOR.)

REGIDOR

¿Qué hacéis de esta suerte aquí?

FRONDOSO

¿Qué ha sucedido, Cuadrado?

REGIDOR

Pesquisidor ha llegado.

ESTEBAN

Echá todos por ahí.

REGIDOR

Con él viene un capitán.

ESTEBAN

Venga el diablo: ya sabéis lo que responder tenéis.

REGIDOR

El pueblo prendiendo van, sin dejar alma ninguna.

ESTEBAN

Que no hay que tener temor. ¿Quién mató al comendador, Mengo?

MENGO

¿Quién? Fuente Ovejuna.

(_Vanse, y salen el_ MAESTRE _y_ UN SOLDADO.)

MAESTRE

¡Que tal caso ha sucedido! Infelice fué su suerte. Estoy por darte la muerte por la nueva que has traído.

SOLDADO

Yo, señor, soy mensajero, y enojarte no es mi intento.

MAESTRE

¡Que a tal tuvo atrevimiento un pueblo enojado y fiero! Iré con quinientos hombres, y la villa he de asolar; en ella no ha de quedar ni aun memoria de los hombres.

SOLDADO

Señor, tu enojo reporta; porque ellos al rey se han dado, y no tener enojado al rey es lo que te importa.

MAESTRE

¿Cómo al rey se pueden dar, si de la encomienda son?

SOLDADO

Con él sobre esa razón podrás luego pleitear.

MAESTRE

Por pleito ¿cuándo salió lo que él[44] le entregó en sus manos? Son señores soberanos, y tal reconozco yo. Por saber que al rey se han dado me reportará mi enojo, y ver su presencia escojo por lo más bien acertado; que puesto que tenga culpa en casos de gravedad, en todo mi poca edad viene a ser quien me disculpa. Con vergüenza voy; mas es honor quien puede obligarme, y importa no descuidarme en tan honrado interés.

[44] El pueblo.

(_Vanse; sale_ LAURENCIA _sola._)

LAURENCIA

Amando, recelar daño en lo amado, nueva pena de amor se considera; que quien en lo que ama daño espera aumenta en el temor nuevo cuidado. El firme pensamiento desvelado, si le aflige el temor, fácil se altera; que no es a firme fe pena ligera ver llevar el temor el bien robado. Mi esposo adoro; la ocasión que veo al temor de su daño me condena, si no le ayuda la felice suerte. Al bien suyo se inclina mi deseo: si está presente, está cierta mi pena; si está en ausencia, está cierta mi muerte.

(_Sale_ FRONDOSO.)

FRONDOSO

¡Mi Laurencia!

LAURENCIA

¡Esposo amado! ¿Cómo a estar aquí te atreves?

FRONDOSO

¿Esas resistencias debes a mi amoroso cuidado?

LAURENCIA

Mi bien, procura guardarte, porque tu daño recelo.

FRONDOSO

No quiera, Laurencia, el cielo que tal llegue a disgustarte.

LAURENCIA

¿No temes ver el rigor que por los demás sucede, y el furor con que procede aqueste pesquisidor? Procura guardar la vida. Huye, tu daño no esperes.

FRONDOSO

¿Cómo que procure quieres cosa tan mal recibida? ¿Es bien que los demás deje en el peligro presente y de tu vista me ausente? No me mandes que me aleje; porque no es puesto en razón que, por evitar mi daño, sea con mi sangre extraño en tan terrible ocasión.

(_Voces dentro._)

Voces parece que he oído, y son, si yo mal no siento, de alguno que dan tormento. Oye con atento oído.

(_Dice dentro el_ JUEZ, _y responden._)

JUEZ

Decid la verdad, buen viejo.

FRONDOSO

Un viejo, Laurencia mía, atormentan.

LAURENCIA

¡Qué porfía!

ESTEBAN

Déjenme un poco.

JUEZ

Ya os dejo. Decid, ¿quién mató a Fernando?

ESTEBAN

Fuente Ovejuna lo hizo.

LAURENCIA

Tu nombre, padre, eternizo[45]. ...

[45] Falta un verso para la redondilla, pero no para el sentido.

FRONDOSO

¡Bravo caso!

JUEZ

Ese muchacho aprieta. Perro, yo sé que lo sabes. Di quién fué. ¿Callas? Aprieta, borracho.

NIÑO

Fuente Ovejuna, señor.

JUEZ

¡Por vida del rey, villanos, que os ahorque con mis manos! ¿Quién mató al comendador?

FRONDOSO

¡Que a un niño le den tormento y niegue de aquesta suerte!

LAURENCIA

¡Bravo pueblo!

FRONDOSO

Bravo y fuerte.

JUEZ

Esa mujer al momento en ese potro tened. Dale esa mancuerda luego.

LAURENCIA

Ya está de cólera ciego.

JUEZ

Que os he de matar, creed, en este potro, villanos. ¿Quién mató al comendador?

PASCUALA

Fuente Ovejuna, señor.

JUEZ

¡Dale!

FRONDOSO

Pensamientos vanos.

LAURENCIA

Pascuala niega, Frondoso.

FRONDOSO

Niegan niños: ¿qué te espantas?

JUEZ

Parece que los encantas. ¡Aprieta!

PASCUALA

¡Ay cielo piadoso!

JUEZ

¡Aprieta, infame! ¿Estás sordo?

PASCUALA

Fuente Ovejuna lo hizo.

JUEZ

Traedme aquél más rollizo; ese desnudo, ese gordo.

LAURENCIA

¡Pobre Mengo! El es sin duda.

FRONDOSO

Temo que ha de confesar.

MENGO

¡Ay, ay!

JUEZ

Comienza a apretar.

MENGO

¡Ay!

JUEZ

¿Es menester ayuda?

MENGO

¡Ay, ay!

JUEZ

¿Quién mató, villano, al señor comendador?

MENGO

¡Ay, yo lo diré, señor!

JUEZ

Afloja un poco la mano.

FRONDOSO

El confiesa.

JUEZ

Al palo aplica la espalda.

MENGO

Quedo; que yo lo diré.

JUEZ

¿Quién lo mató?

MENGO

Señor, Fuente Ovejunica.

JUEZ

¿Hay tan gran bellaquería? Del dolor se están burlando. En quien estaba esperando, niega con mayor porfía. Dejaldos; que estoy cansado.

FRONDOSO

¡Oh, Mengo, bien te haga Dios! Temor que tuve de dos, el tuyo me le ha quitado.

(_Salen con_ MENGO, BARRILDO _y el_ REGIDOR.)

BARRILDO

¡Vítor, Mengo!

REGIDOR

Y con razón.

BARRILDO

¡Mengo, vítor!

FRONDOSO

Eso digo.

MENGO

¡Ay, ay!

BARRILDO

Toma, bebe, amigo. Come.

MENGO

¡Ay, ay! ¿Qué es?

BARRILDO

Diacitrón.

MENGO

¡Ay, ay!

FRONDOSO

Echa de beber.

BARRILDO

...Ya va[46].

[46] Falta el principio del verso.

FRONDOSO

Bien lo cuela. Bueno está.

LAURENCIA

Dale otra vez a comer.

MENGO

¡Ay, ay!

BARRILDO

Esta va por mí.

LAURENCIA

Solemnemente lo embebe.

FRONDOSO

El que bien niega bien bebe.

REGIDOR

¿Quieres otra?

MENGO

¡Ay, ay! Sí, sí.

FRONDOSO

Bebe, que bien lo mereces.

LAURENCIA

A vez por vuelta las cuela.

FRONDOSO

Arrópale, que se hiela.

BARRILDO

¿Quieres más?

MENGO

Sí, otras tres veces. ¡Ay, ay!

FRONDOSO

Si hay vino pregunta.

BARRILDO

Sí hay: bebe a tu placer; que quien niega ha de beber. ¿Qué tiene?

MENGO

Una cierta punta[47]. Vamos; que me arromadizo.

[47] _Punta_, sabor agrio del vino. Mengo ha debido hacer antes un gesto de desagrado.

FRONDOSO

Que [beba][48], que éste es mejor. ¿Quién mató al comendador?

[48] _El original_, lea.

MENGO

Fuente Ovejunica lo hizo.

(_Vanse._)

FRONDOSO

Justo es que honores le den. Pero decidme, mi amor, ¿quién mató al comendador?

LAURENCIA

Fuente Ovejuna, mi bien.

FRONDOSO

¿Quién le mató?

LAURENCIA

Dasme espanto. Pues Fuente Ovejuna fué.

FRONDOSO

Y yo ¿con qué te maté?

LAURENCIA

¿Con qué? Con quererte tanto.

(_Vanse, y salen el_ REY _y la_ REINA _y_ MANRIQUE [_luego_].)

ISABEL

No entendí, señor, hallaros aquí, y es buena mi suerte.

REY

En nueva gloria convierte mi vista el bien de miraros. Iba a Portugal de paso, y llegar aquí fué fuerza.

ISABEL

Vuestra majestad le tuerza, siendo conveniente el caso.

REY

¿Cómo dejáis a Castilla?

ISABEL

En paz queda, quieta y llana.

REY

Siendo vos la que la allana no lo tengo a maravilla.

(_Sale_ DON MANRIQUE.)

MANRIQUE

Para ver vuestra presencia el maestre de Calatrava, que aquí de llegar acaba, pide que le deis licencia.

ISABEL

Verle tenía deseado.

MANRIQUE

Mi fe, señora, os empeño, que, aunque es en edad pequeño, es valeroso soldado.

([_Vase, y_] _sale el_ MAESTRE.)

MAESTRE

Rodrigo Téllez Girón, que de loaros no acaba, maestre de Calatrava, os pide, humilde, perdón. Confieso que fuí engañado, y que excedí de lo justo en cosas de vuestro gusto, como mal aconsejado. El consejo de Fernando y el interés me engañó, injusto fiel; y ansí, yo perdón, humilde, os demando. Y si recebir merezco esta merced que suplico, desde aquí me certifico en que a serviros me ofrezco, y que en aquesta jornada de Granada, adonde vais, os prometo que veáis el valor que hay en mi espada; donde sacándola apenas, dándoles fieras congojas, plantaré mis cruces rojas sobre sus altas almenas; y más quinientos soldados en serviros emplearé, junto con la firma y fe de en mi vida disgustaros.

REY

Alzad, maestre, del suelo; que siempre que hayáis venido seréis muy bien recibido.

MAESTRE

Sois de afligidos consuelo.

ISABEL

Vos, con valor peregrino, sabéis bien decir y hacer.

MAESTRE

Vos sois una bella Ester, y vos un Jerjes divino.

(_Sale_ MANRIQUE.)

MANRIQUE

Señor, el pesquisidor que a Fuente Ovejuna ha ido, con el despacho ha venido a verse ante tu valor.

REY

Sed juez de estos agresores.

MAESTRE

Si a vos, señor, no mirara, sin duda les enseñara a matar comendadores.

REY

Eso ya no os toca a vos.

ISABEL

Yo confieso que he de ver el cargo en vuestro poder, si me lo concede Dios.

(_Sale el_ JUEZ.)

JUEZ

A Fuente Ovejuna fuí de la suerte que has mandado, y con especial cuidado y diligencia asistí. Haciendo averiguación del cometido delito, una hoja no se ha escrito que sea en comprobación; porque conformes a una, con un valeroso pecho, en pidiendo quién lo ha hecho, responden: «Fuente Ovejuna». Trecientos he atormentado con no pequeño rigor, y te prometo, señor, que más que esto no he sacado. Hasta niños de diez años al potro arrimé, y no ha sido posible haberlo inquirido ni por halagos ni engaños. Y pues tan mal se acomoda el poderlo averiguar, o los has de perdonar, o matar la villa toda. Todos vienen ante ti para más certificarte: de ellos podrás informarte.

REY

Que entren, pues vienen, les di.

(_Salen los dos_ ALCALDES, FRONDOSO, _las mujeres y los villanos que quisieren._)

LAURENCIA

¿Aquestos los reyes son?

FRONDOSO

Y en Castilla poderosos.

LAURENCIA

Por mi fe, que son hermosos: ¡bendígalos San Antón!

ISABEL

¿Los agresores son éstos?

ALCALDE ESTEBAN

Fuente Ovejuna, señora, que humildes llegan agora para serviros dispuestos. La sobrada tiranía y el insufrible rigor del muerto comendador, que mil insultos hacía, fué el autor de tanto daño. Las haciendas nos robaba y las doncellas forzaba, siendo de piedad extraño.

FRONDOSO

Tanto, que aquesta zagala, que el cielo me ha concedido, en que tan dichoso he sido que nadie en dicha me iguala, cuando conmigo casó, aquella noche primera, mejor que si suya fuera, a su casa la llevó; y a no saberse guardar ella, que en virtud florece, ya manifiesto parece lo que pudiera pasar.

MENGO

¿No es ya tiempo que hable yo? Si me dais licencia, entiendo que os admiraréis, sabiendo del modo que me trató. Porque quise defender una moza de su gente, que con término insolente fuerza la querían hacer, aquel perverso Nerón, de manera me ha tratado, que el reverso me ha dejado como rueda de salmón. Tocaron mis atabales tres hombres con tal porfía, que aun pienso que todavía me duran los cardenales. Gasté en este mal prolijo, por que el cuero se me curta, polvos de arrayán y murta más que vale mi cortijo.

ALCALDE ESTEBAN

Señor, tuyos ser queremos. Rey nuestro eres natural, y con título de tal ya tus armas puesto habemos. Esperamos tu clemencia, y que veas, esperamos, que en este caso te damos por abono la inocencia.

REY

Pues no puede averiguarse el suceso por escrito, aunque fué grave el delito, por fuerza ha de perdonarse. Y la villa es bien se quede en mí, pues de mí se vale, hasta ver si acaso sale comendador que la herede.

FRONDOSO

Su majestad habla, en fin, como quien tanto ha acertado. Y aquí, discreto senado, FUENTE OVEJUNA da fin.

=I.=

Die Iberische Mutter Gottes fuhr spazieren.

Aus der Tiefe ihres kerzenerhellten blaugoldschimmernden Tempelchens vor dem Eingang zum Schönen Platz am Kreml war sie von ehrfürchtigen Händen in den Wagen gehoben worden.

Da saß sie nun im prächtigen Vierspänner, ihrer ständigen Equipage, breit auf dem Vordersitz, ihr gegenüber zwei Priester in reichen scharlachroten Gewändern, Kreuz und Weihrauchgefäß vor sich hinhaltend.

Irgend eine der kleinern Glocken im Kreml bimmelte und bimmelte. Hin und wieder nur unterbrach ein vereinzelter tiefer Glockenton, lang nachdröhnend und wie verträumt, dies helle Geläute. Hoch über den verschneiten Straßen klang es unermüdlich, mit dringlicher Monotonie, in den Winterwind hinein.

Die Menge umringte den Wagen so nahe, als sie es vermochte, junge Gesichter und alte, bärtige bückten sich in gleich demutvollem Eifer, um einen Kuß auf das wunderthätige Bild zu erhaschen oder wenigstens auf den Rahmen daneben.

Ein paar elegante Offiziere, die über den Woßkreßenskiplatz herkamen, machten mitten auf dem Fahrdamm Halt, beugten das Knie in den Schnee und bekreuzigten sich feierlich mit bis zur Strenge ernsten Mienen.

Täglich fuhr die Iberische Mutter aus, um allen Besuchsanforderungen zu genügen, dennoch mußte oft ihre Gegenwart in einem Haus wochenlang vorher erfleht werden, damit sie noch Zeit dafür fand.

Langsam lenkte der imposante Kutscher, trotz der empfindlichen Kälte entblößten Hauptes, seine vier Rappen aus dem Menschenhaufen heraus.

Viele blieben noch stehn, um ihm nachzuschauen. Auf den Stufen zum Tempelchen lagerten Pilger, Bastschuhe an den tücherumwickelten Füßen, den Stab in der Hand. Mit ihren Anliegen wandten sie sich jetzt an die Kopie des Bildes, die stellvertretend im Heiligtum hing, und steckten betend brennende Wachskerzen davor auf.

So mehrte sich drinnen immer noch Licht um Licht zu erhöhtem Glanze, -- von außen anzusehen wie eine mächtige gelbflimmernde Sonne, die mitten im nüchternen Alltag des Straßenlebens gleich einem leuchtenden Geheimnis dastand und winkte und winkte --.

Die Mutter Gottes im Vierspänner hatte mit nicht gar vielen Equipagen zu konkurrieren. Wer sie fahren sah, konnte sie gut für die große Dame Moskaus halten und für den Inbegriff des heiligen Mütterchens Moskau selbst.

Was da auf dem hartgefrorenen Schnee an Fuhrwerken vorüberglitt, waren fast nur kleine, niedrige Schlittchen, wie sie für wenige Kopeken sogar dem Volk zugänglich sind. Weiber mit Sack und Pack befanden sich häufig drin, Bauern in hoch um die Ohren geschlagenen Schafpelzen. Seltener schon flog eine Troika des Weges dahin, und, zugleich mit dem lustigen schellenläutenden Dreigespann, vielleicht irgend ein Lied, angestimmt von den Insassen, -- ein Lied, wie es in den Theebuden zur Harfe gesungen wird oder in Sommernächten vor der Thür der Dorfhütten.

Das zitterte dann mit dem nachschwingenden Glockenton wundersam in eins zusammen, -- selbst dann wundersam in eins, wenns zufällig ein Tanzlied war. Auch dann mußte es der Iberischen Mutter heimisch entgegenklingen.

Und auch unter den Fußgängern begegneten ihr vorherrschend ihre ureigensten Kinder, Kinder des Volks. Nicht das Proletariat großer Städte, wie es gern die entlegeneren Gassen füllt, sondern Volk, -- das Volk zu Hause auf seinen breiten Straßen und Plätzen. In der ihm zugehörigen Tracht schritt es einher, nicht in abgelegten Almosenkleidern Reicherer oder deren Nachahmung, und diese Tracht überwog so sehr, daß sich die Andersgekleideten, die Allerweltstypen, fast darunter verloren.

Das alte Moskau, -- zumal in der winterlichen Frühdämmerung einer solchen Nachmittagsstunde, -- nahm sich beinahe aus, als sei es im Grunde seines Herzens ein Riesendorf, zutraulich herumgebaut um die allwaltende Herrlichkeit und Heiligkeit der Kremlhöhe.

Rot und grün und blau an Dächern oder Mauerwerk, in Farben, wie sie Kinder am liebsten auf ihren Bilderbogen anbringen, schauten die Häuser zum großen Kreml empor. Und in Rot und Grün und Blau antwortete er ihnen von der Höhe seiner Kuppeln und Paläste, väterlich ihnen angepaßt, mit ihnen verschmelzend, und malte noch bunte Sternchen oder Streifen mitten hinein in sein Gold.

Mit dem Golde aber übertrumpfte er sie, überstrahlte er sie, mit dem Golde übertönte er alles wie mit einem lauten Lobgesang, sodaß sie gleich darauf doch wieder ganz klein unter ihm dalagen und ganz verstummt trotz ihrer beredten Farben. Und ein andres Gold war es zu jeglicher Stunde, zu jeder jedoch ein königliches, vom ersten Tagesgrauen an, das über Moskau aufging, bis tief in die tiefste Nacht, denn keine gab es, tief genug, um das Gold ganz auszulöschen.

Immer war es da, ob breit entfaltet in seinem selbstverständlichen Glanze oder geheinmisvoll gesammelt wie eine Leuchte von innen her, die sich nur verstohlen verrät. Immer war es da, allen gegenwärtig, von den äußersten Kreuzspitzen der Kathedralen an bis hinein in das verborgenste Dunkel der Kirchenräume und selbst bis hinab in den geschlossnen Wagen, worin die Iberierin durch die Straßen fuhr, feierlich umblitzt von Goldfunken und dem vielfarbigen Schimmer ihres köstlichen Geschmeides. --

Sie machte nur eine kurze Fahrt, schon in einer Seitenstraße der Twerskaja schien ihr Ziel erreicht. Unter einem erneuten Auflauf von Menschen, die leise beteten, sich bekreuzigten und einen Kuß anzubringen suchten, wurde sie hinausgehoben, um den inbrünstig Harrenden entgegengetragen zu werden, denen ihr Besuch galt, und deren Thränen sie trocknen, deren Qual sie bannen, oder deren Jubel über eine Glücksfügung sie Weihe und Segen erteilen sollte.

Am Fenster eines hölzernen Miethauses schräg gegenüber standen zwei junge Mädchen und sahen, aneinander gelehnt, der Scene auf der Straße zu.

»Ach Rußland -- Rußland! Mir ist doch wieder, als ob ich nach Asien zurückgekehrt wäre,« sagte die Aeltere kopfschüttelnd, »traurig ist es! Ich wundre mich, daß du nur dazu lachst, Sophie.«

Sophie kehrte sich vom Fenster ab, weil es nichts mehr zu sehen gab. Sie entgegnete mit einem sanften, begütigenden Stimmchen: »Es ist nicht so schlimm. Vielleicht noch ein bißchen Mittelalter, aber es kann auch etwas ganz Feierliches bekommen, mitunter. Dann lache ich auch nicht. -- Man muß nur nicht grade als Studentin frisch aus dem Auslande angereist sein!«

»Wir haben keinerlei Grund, uns für dies Mittelalter zu begeistern, Sophie. Sind wir etwa Russen? Und selbst wenn wirs wären --«

Sophie war nach dem andern Fenster gegangen, wo neben einer Gruppe wohlgepflegter hoher Blattpflanzen ein Schaukelstuhl stand.

»Sind wir auch nicht gradezu Russen, so sind wir doch hier zu Hause,« meinte sie zögernd. »Und eigentlich möchte ich manchmal, wir wärens noch mehr! Wären zum Beispiel in einem stockrussischen Gymnasium erzogen worden, -- wenigstens ich, Schwesterchen.«

»-- Warum --?!«

Sophie blieb die Antwort auf diese erstaunte Frage schuldig.

Ihre zartgliedrige Gestalt dehnte sich lang aus im Schaukelstuhl, und sie legte den blonden Kopf mit seinen zwei schimmernden Flechten, die ihn kranzförmig umwanden, so weit zurück an die Stuhllehne, daß ihr Blick zur Zimmerdecke emporsah, anstatt auf die Schwester.

Erst nach einer kleinen Pause bemerkte sie ablenkend: »Uebrigens: diese niedrigen Decken abgerechnet, -- findest du nicht auch, Cita, daß unsre jetzige Wohnung ganz ungeheuer behaglich ist? Ich freute mich so, als wir wegen Mas vieler Lehrstunden in dies gute Viertel ziehen mußten.«

Cita hatte sich auf den Fenstersims gehockt und strich sich in einer ihr eigentümlichen hastigen Bewegung mit der Hand durch ihr kurzverschnittenes welliges ganz dunkelblondes Haar.

»Gewiß, -- sehr behaglich habt ihr es,« gab sie zerstreut zu, »aber es sollte wohl selbst der vertracktesten Wohnung schwer fallen, unbehaglich zu wirken, wenn unsre Mama sie bewohnt und einrichtet. -- Aber daß sie dies Viertel gewählt hat, ist auch abgesehen von den Lehrstunden gut. Die meisten ihr bekannten Häuser liegen nicht weit von hier. Ich meine: das ist gut -- besonders für später.«

»Wie denn: für später?«

Cita hob ihren hübschen Bubenkopf und blickte auf die Schwester.

»Verstehst du mich nicht? -- -- Für später, wenn sie hier allein ist, weil auch du irgendwo im Auslande studierst, -- Medizin --«

Sophie lachte hell auf, wie über einen Scherz. »Was dir nicht alles einfällt! Daran denkt doch niemand im Traum!« bemerkte sie und wippte leise mit dem Schaukelstuhle.

Cita zog unwillig die dunkeln feinen Augenbrauen zusammen. »Ach Sophie, laß doch die Flausen, hinter denen du dich versteckst. Gewiß denkt jemand daran, im Traum und im Wachen: nämlich du selbst. Und aus diesem einzigen Grunde bedauertest du offenbar plötzlich, nicht ein stockrussisches Gymnasium hinter dir zu haben. Du erwägst in deiner Ratlosigkeit: könnt ich wenigstens hier --, wenn nicht schon im Auslande --«

»Ja, -- Ma verlassen --: das thu ich eben nicht!« fiel Sophie erregt ein.

Cita entgegnete sehr ruhig: »Zeit wärs, zu wissen, was du selbst willst. Du bist neunzehn, hast seit Ostern dein Diplom. In dem Alter war ich schon fort. Und in anderthalb Jahren werd ich promoviert haben, -- wenn nicht eher.«

»Mein Gott, damit brauchst du nicht zu protzen!« sagte Sophie empfindlich, »-- so, wie Ma dir alle Wege geebnet hat. Sogar noch ehe Vaters Lieblingsschwester starb und jeder von uns das kleine Legat vermachte --«

»Ich protze nicht. Ma war reizend, in jeder Beziehung. Es spornt mich nur an, um so energischer ans Ziel zu gelangen.«

»Nun -- und was weiter? Ich glaube durchaus nicht, daß weibliche Juristen heutzutage die geringsten Aussichten haben,« erklärte Sophie im Ton einer gezwungenen Bewunderungslosigkeit und wippte heftiger.

»Vielleicht heute noch nicht. Aber morgen. Uebermorgen meinetwegen. Wir Frauen arbeiten eben an einem Stück Zukunft. -- -- Und inzwischen, da will ich mir schon durchhelfen. Du mußt nicht glauben, daß ich nicht mehr vermag, als juristisch fachzusimpeln.«

»Ach nein, hoffentlich nicht. Denn _das_ würde unsrer Ma auch ganz schrecklich sein.«

Sie schwiegen beide.

Cita trat vom Fenster fort und fing an, langsam auf und ab zu gehn, wobei sie die Arme auf dem Rücken verschränkte und den Kopf ein wenig gesenkt hielt, wie ein grübelnder Feldherr.

Vor dem Schreibtisch ihrer Mutter, der, quergestellt, ein Drittel des Zimmers durchschnitt, blieb sie einige Augenblicke stehn.

Er war mit Büchern und Schulheften bedeckt; aus der Mitte all dieser Tagesarbeit erhob sich ein italienischer Olivenholzrahmen mit durchbrochen gearbeiteten verschließbaren Thüren. Dahinter verbarg sich des jung verstorbenen Gatten Bild.

An der einen Wand dahinter hingen mehrere Radierungen von seiner Hand, in schlichte dunkle Holzstreifen eingefaßt: sie stammten aus den Jahren seiner kurzen Ehe, aus der Zeit vollen Glückes und voller Künstlerhoffnungen, -- unten in Italien verlebt.

An der andern Wand hinter dem Schreibtisch eine ganze Gruppe Familienporträts, darunter sehr alte, die mit sichtlicher Pietät hier zusammengestellt waren. Zwei davon blasse Pastellbildchen: der Großvater mütterlicherseits, Martin, mit mächtiger schwarzer Halsbinde und nach vorn gebürstetem grauem Haar, ein kluger, fast bedeutender Kopf. Daneben die reizende alte Großmutter, von der Cita und Sophie ein gut Teil Anmut als Erbe erhalten hatten.

»Für Ma wär es auch tausendmal besser gewesen, nicht hier stecken zu bleiben,« entfuhr es Cita.

Sie stand und betrachtete die Bilder. »Mit ihrer Begabung, ihren Talenten hätte sie etwas werden müssen. Aber freilich, hier in Rußland, wo sie einfach den reichen Kaufleuten die Rangen unterrichten muß --«

Sophie hatte die Augen geschlossen.

»Arme liebe Ma!« sagte sie leise, »du lieber Gott, die konnte eben nicht Juristerei studieren. Dabei wären wir zwei armen kleinen Würmer geschwind genug verhungert. -- -- Und hier in Rußland gab es doch wenigstens Lebensmöglichkeiten, und die guten Anknüpfungen von unserm Großvater-Gymnasialdirektor her, und schließlich doch auch Tante Ottilie -- --. Aber schwer und schrecklich muß es gewesen sein --«

Sophie unterbrach sich, dann fügte sie in gequältem Ton hinzu: »Du und ich, wir sind undankbare Scheusale! Wir, mit unserm dummen Ehrgeiz -- --«

Cita ging schon wieder mit verschränkten Armen auf und ab. Es entfuhr ihr ungeduldig: »Deine Logik ist einfach schauderhaft. Grade das Gegenteil muß daraus gefolgert werden: in uns beiden lebt ja doch Ma weiter, in uns muß sie also etwas über sich selbst hinaus erreichen. Das ist doch wahrhaftig die einzige rationelle Art von Kindesliebe.«

»Ach, ich weiß nicht, ob das Kindesliebe ist. -- -- Und ob Kindesliebe rationell zu sein hat,« murmelte Sophie.

Cita bemerkte seufzend: »Du redest wirklich oft wie ein ganz unentwickelter Mensch. Wenn ich nur nicht so gut wüßte, woher das kommt: es ist ganz einfach Bangigkeit, du wehrst dich gegen deine eigne bessere Erkenntnis. Die reinste Feigheit.«

»Das verbitt ich mir denn doch!« rief Sophie aufgebracht.

Der Schaukelstuhl flog. Sie fing an zu husten.

Die Schwester lenkte ein. »Verzeih. Beleidigen wollt ich dich nicht. Du hast recht: das darf man nicht. Fest zusammenstehn müssen wir Frauen vielmehr. Uns gegenseitig unsre besten Freunde sein. Ich schelte dich als dein Freund, Schwesterchen, -- zu deinem Besten. Bin voll Sehnsucht und Ehrgeiz für dich, -- -- möchte dir helfen, -- und nicht nur mit Worten. Nein, nein, bauen sollst du auf mich dürfen von Grund aus.«

Sophie schwieg. Sie hatte die Augen voll Thränen, und aus Furcht, in der Stimme Thränen zu verraten, blieb sie wieder die Antwort schuldig.

Cita drängte auch nicht in sie. Sie trat langsam an das breite Büchergestell aus kunstvoll zurecht getischlertem, braun angestrichenem Birkenholz, das in Mannshöhe die ganze Hinterwand einnahm, und zog irgend ein Buch heraus.

Schon war es längst nicht mehr hell genug im Zimmer, um zu lesen, doch nahm sie Band um Band und blätterte zerstreut darin.

Hier fand sich allerlei noch von Großvaters, des Schulmanns, Zeiten her zusammen. Und manches wohl auch, was der Mutter nur ihr Beruf als Lehrerin praktisch aufgenötigt hatte. Aber der Mehrzahl nach standen die Bücherreihen gedrängt voll von den höchsten Schätzen, die Menschengeist gehoben hatte. Und all das war, Band für Band mühselig angeschafft, -- Band für Band

benutzt, abgegriffen, genossen --.

Das Mädchen kam herein und brachte die Lampe.

Sie war eine noch sehr junge und ein wenig blöd dreinschauende Person, die unschlüssig stehn blieb und Sophie fragend anblickte.

Diese erhob sich schweigend aus ihrem bequemen Stuhl und ging mit ihr hinaus. Das späte Mittagessen konnte man Stanjka nicht allein anrichten lassen. Denn so oft man das, nach allen guten Belehrungen, probeweise gethan hatte, wurde Stanjka düster und fing an zu weinen. Sie setzte sich dann auf die kleine Bank am Herd und klagte und betete unter Thränen zur Mutter Gottes, die sie laut als Zeugin dafür anrief, daß es ihr sicher nicht gegeben sei, ein Mittagessen wohlbekömmlich herzustellen.

Das kleine Heiligenbild, braun und unkenntlich hinter seiner blanken Zinnbekleidung, hing vorschriftsmäßig in der Küchenecke, sah immer zu und mußte es folglich genau wissen.

Daß es zufällig gar keine Muttergottes war, vielmehr ein heiliger Nikolaus, das hatte sich Stanjka nicht klar gemacht, jedenfalls focht es sie nicht weiter an. Wenn sie nicht grade »höhere« Arbeit verrichten sollte, sondern sich im Gröbern tummeln durfte, blieb sie strahlender Laune und bewältigte alles mit Herzenslust.

Während Sophie noch mit ihr in der Küche herumwirtschaftete, schellte es laut und dringlich.

Cita war schon gegangen, um die Wohnungsthür zu öffnen. Ihre Mutter stand davor, noch etwas atemlos vom raschen Gange.

»Da hab ich richtig vergessen meinen Schlüssel mitzunehmen, -- mußte schellen,« sagte sie und trat hastig ein, »-- ein Wind draußen, Kind, -- Sophie ist doch nicht etwa unnütz an die Luft gegangen?«

»Aber nein, Ma. Wie müde mußt du heute sein, du Arme.«

Cita nahm ihr sorglich den leichten Grauwerkpelz ab und küßte sie.

»Ich danke dir, Kind. Gewiß habt ihr schon einen Wolfshunger, was? Ich lief, was ich konnte,« bemerkte die Mutter, indem sie sich die Fellüberschuhe von den Füßen streifte.

»So! Und nun bin ich wieder Mensch! Feierabend läutets, und die Arbeit ist gethan,« sagte sie froh, »-- und für heute ganz gethan: am Abend brauche ich nicht mehr fortzugehn. Wir wollens aber auch herzhaft genießen, ihr Kinder.«

Wer ihre Stimme so aus dem noch unerleuchteten Vorflur vernahm, konnte dahinter leicht ein junges Geschöpf vermuten. Alle Ueberanstrengung, aller Mißbrauch dieser Stimme hatten nicht vermocht, ihr den eigentümlichen Schmelz zu nehmen. Den Gesichtszügen selbst sah man die vierzig Jahre eher an. Sogar schon einzelne graue Haare mischten sich an den Schläfen in das volle weiche Braun, das Cita in lichterer Schattierung besaß, und das sich auch bei der Mutter hier und da übermütig zu locken versuchte, soweit der schlichte Knoten tief im Nacken das zuließ.

Die Mutter erreichte ihre Aelteste nicht ganz an Größe, und ihre geschmeidige Gestalt hatte ehemals entschiedene Neigung zur Fülle gezeigt; jetzt jedoch vereitelte das anstrengende Tagewerk gründlich jeden Ansatz dazu. So blieb sie schlank, nahezu mager, und konnte dadurch auf Augenblicke fast mädchenhaft wirken.

Als die Mutter in ihrem Schlafgemach verschwunden war, um sich ein wenig menschlich herzurichten, wie sie es nannte, machte sich Cita dran, in der kleinen schmalen Eßstube neben dem Wohnzimmer den Tisch zu decken. Doch war sie noch voll Nachdenklichkeit, und es ging ihr langsam von der Hand.

Dies schmale Eßstübchen, nicht ohne Grund »der Spalt« geheißen, war bei der Wohnungseinrichtung an Möbeln zu kurz gekommen. Die Mutter hatte ein paar Bauerntruhen hineingestellt und rund um den Tisch einfache Sitzschemel von gleich ländlicher Abstammung. Dann erhandelte sie jedoch auf dem großen Trödelmarkt, den das Moskauer Volk in der Sonntagsfrühe abhält, noch hier und da ein Stück volkstümlichen Kunstgewerbes, wodurch der arme Spalt einen gewissen Glanz erhielt, -- so durch ein Wandbort aus dunkelm in Spitzenmuster geschnitztem Holz mit grellen Malereien auf Goldgrund, und durch einen originellen Stuhl, dessen ganzes Hintergestell aus einem rotlackierten Krummholz hergestellt war, wie es die Pferde im russischen Gespann tragen.

Am einzigen Fenster, an dem der rote Stuhl stand und repräsentierte, hingen buntbestickte kleinrussische Tücher als Vorhänge nieder, und auch das grobleinene Tischtuch wies eine solche bunte Bauernstickerei an der Kante auf.

Als die Mutter wieder eintrat, trug sie statt des dunkeln knappen Straßenkleides einen bequemen Hausanzug von tiefrotem Flanell. Sie kam an den Tisch zur Tochter, und, ohne daß diese es bemerkte, schob sie jedes Gerät auf dem Tisch ein wenig anders und gefälliger zurecht.

Als sie aber dann einen Teller mit allerlei Obst hernahm, den Cita in die Mitte gestellt hatte, und sorgfältig begann, die Orangen und die blassen, länglichen Krimäpfel von ihren dünnen Papierhülsen zu befreien und sie in einer Krystallschale zu ordnen, da meinte die Tochter mit einem Lächeln: »So viel Mühe um das bißchen Aeußerlichkeit, Ma, müde, wie du doch bist. Schmecken nun etwa die Früchte besser?«

Die Mutter nickte, indem sie das Lächeln erwiderte. Ueber die Schale geneigt, sog sie den kühlen Duft des Obstes in sich ein.

»Auf alle Fälle schmecken sie besser,« sagte sie, »und außerdem machen sie, daß man auf Augenblicke das ganze Leben besser genießt, während man sie verspeist. Man genießt sie ja nicht nur um des lieben Futters willen als bloße Magenfreude, nicht wahr?«

Als Cita nichts antwortete, richtete sie sich auf und faßte ihre Aelteste zärtlich um die Schulter.

»Aber du sollst dich hier keineswegs mit Hausarbeit plagen, mein lieber kleiner Professor du. Hast nun einmal eine Sybaritin zur Mutter. Bist aber rechtschaffen zerarbeitet angekommen und sollst nichts thun, als es dir wohl sein lassen, -- faulenzen. Wenigstens einstweilen, -- bis über Weihnachten hinaus.«

Und mit einem unterdrückten Seufzer fügte sie leiser hinzu: »Schnell genug verlier ich dich ja wieder.«

Sie fuhr sich mit der Hand über die Augen, wie um den störenden Gedanken zu verscheuchen. Als nun Sophie, etwas erhitzt und eilig, von Stanjka gefolgt, hereinkam, nickte sie der jüngern Tochter schon wieder wohlgemut zu.

»Also zu Tisch, Kinder! Wir wollen es uns schmecken lassen,« sagte sie und hob den Deckel von der dampfenden Terrine mit roter Beetensuppe, in der Saucischen und Schinkenschnitten schwammen.

Sophie küßte die Mutter, ehe sie sich ihr gegenüber setzte.

»Ich bin nicht in den Mädchenkursen gewesen, weil du es des Wetters wegen nicht wolltest. Dafür hab ich ziemlich lange Geige geübt, und später habe ich über den Büchern gesessen, die Doktor Tomasow neulich brachte,« berichtete sie über ihren Tag, »er hat gewiß noch herrliche Dinge in seiner Bibliothek, aber er sagt, ich möchte mich erst an diese Werke halten.«

»Thu blind, was er sagt,« bemerkte die Mutter, »aber warum ißt du mir so wenig, Kind? Nimmst du nicht von der sauren Sahne zur Suppe? Ich fürchte, das Herumstehn in der heißen Küche ist nichts für dich; -- es raubt dir den Appetit.«

»O nein! Ich esse schon noch.«

Cita hatte auf den Lippen, zu äußern: »Die berühmte Haushaltungsarbeit ist eben lange nicht so gesund, wie ausposaunt wird.«

Aber sie schwieg noch immer. Es war so entsetzlich schwer, in Mas Gegenwart ein spöttisch gefärbtes Wort mit dem nötigen Selbstbewußtsein herauszubringen.

Wie ein Unrecht wurde es gleich, denn die Mutter hätte den Spott darin nicht bemerkt. Für Spott fehlte ihr das aufnehmende Organ. Sie wäre ihm gleichsam mit offnen Armen entgegen gegangen und hätte erwidert: »Meinst du wirklich, Kind?« und dann hätte sie versucht, mit vereinten Kräften, mit Citas eigner Hilfe, ausfindig zu machen, was zu thun sei, -- -- und ob nicht lieber Ma selber beim Heimkehren von den vielen Stunden jedesmal erst noch kochen solle --.

Die Mutter unterbrach ihren Gedankengang. Als das Fischgericht auf den Tisch kam und sie davon austeilte, sagte sie: »Allernächstens, wenn ich nach Hause komme, sorge ich für einen großen Weihnachtsbaum. Es ist Zeit, sich nach einem umzusehen. In den letzten paar Tagen vor dem Festabend steigen sie im Preise. -- Diesmal müssen wir das Allerschönste haben, was es überhaupt gibt.«

Beide Mädchen sahen einander unwillkürlich, wie auf Verabredung, an.

»Einen Baum --?« fragte Sophie und stocherte im Fisch auf ihrem Teller.

»Ja, sicherlich. Etwa nicht? Warum denn nicht, ihr Kinder?«

»Wir haben doch voriges Jahr auch keinen gehabt.«

»Nein. Das lag jedoch an Zufällen. Wir konnten nicht gut anders, als bei Tante Ottilie sein. Und dann waren wir ja auch so traurig getrennt und verwaist, ohne unsre Cita.«

Cita warf einen dankbaren Blick auf die Mutter.

»Natürlich können wir gern einen Baum haben, -- warum denn nicht, Sophie?« bemerkte sie; »wenn Ma es doch gern sieht, wollen wir jedenfalls einen haben, -- den allerschönsten. -- Aber -- -- was werden wir mit dem Baum nur anfangen, Ma? Eigentlich gehören Kinder mit dazu.«

Die Mutter lächelte fein.

»Laß uns einen Abend lang Kinder sein, Liebste. Da wir zusammen sind, haben wir reichen Grund dazu, -- haben wir reich beschert bekommen.«

Cita schwieg. Sophie sagte für sie: »Ich weiß schon, wie es Cita meint. Alle Welt will ja gern sich wie ein Kind fühlen. So ganz unbefangen fröhlich sein. Aber, wenn man es absichtlich versucht, so gelingt es nie recht. Man _ist_ eben doch kein Kind. Man kann nicht ungezwungen so thun, -- es wird so gezwungen --«

»Das ist auch ganz natürlich,« fiel Cita, mit Fischessen beschäftigt, ein, »denn man kann doch eben nicht ganz den schweren, den wirklichen Ernst des Lebens vergessen. Man drängt ihn nur für einen Abend lang in den Hintergrund. Ja, _das_ kann man, künstlich. Aber dahinter, -- da steht er doch immer da --.« Sie war voll Eifer, mehr darüber zu sagen, indessen eine Gräte kam ihr dazwischen.

Beinah entschlüpfte es der Mutter: »-- Huh --! ihr Kinder! Macht ihr euch denn wirklich schon das Leben zum ›bösen Mann‹ im Hintergrunde von allem? Ist euch denn wirklich stets so schaudererregend ernsthaft zu Mute --?«

Aber sie sprach das nicht aus. Sie fürchtete, die Mädchen könnten argwöhnen, sie habe dabei insgeheim auf dem Grunde der Seele ein Lächeln über sie beide.

Und sie fürchtete auch, die Mädchen könnten sie für entsetzlich oberflächlich halten. Das letztere war sogar das Wahrscheinlichere --.

Sie sah ihre beiden Ernsthaften mit einem tiefen Blick voll Güte an.

»Aber nun wollen wir dennoch, während wir vor unsern Tellern sitzen, uns bemühen, so zu thun, als ob das Leben ganz annehmbar wäre, -- was meint ihr? Aus hygienischen Rücksichten!« schlug sie munter vor, und das Lächeln vom verborgenen Seelengrunde kam ganz leise herauf und spielte verhalten um ihren Mund.

Das Fischgericht war hinausgetragen worden, und sie saßen beim Obst, als ein unerwarteter Besuch hereinkam.

»Ach, Ottilie, du! Wie lieb von dir. Du bekommst auch gleich dein Schälchen Kaffee, -- starken,« sagte die Mutter.

»Nur auf einen Sprung! Ich war grade in eurer Nähe,« entgegnete ihre Schwester und begrüßte sie, »-- weißt du, man trifft dich ja eigentlich nie, sonst käm ich nicht so selten.«

Ein ganzer Strom von Winterluft wehte mit ihr ins Zimmer. Hut und Handschuhe hatte sie garnicht abgelegt.

Sophie schob den Stuhl aus der Fensterecke, der als Lehne das Joch besaß, an den Tisch heran, denn auf den kurzbeinigen Schemeln saß ihre Tante höchst ungern.

»Danke,« bemerkte diese und nickte ihr zu, während sie Platz nahm, »-- es ist wirklich euer einziger Stuhl, -- wenigstens hat er einen Rücken, wenn man sich auch halb wie ein Pferd dabei vorkommt. -- Nun, das macht nichts. Traulich ist es doch bei euch, wie jedesmal.«

Sie sagte es mit einer Art von liebevollem Neid. Traulich war es wirklich, und eine solche heitre Wärme, von irgend woher, über allem --.

Saß doch Marianne, in ihrem tiefroten Hausanzug, der sie nirgends beengte, und doch seltsam schmückte, da wie ein Bild der Ruhe und des Genusses. Die feierte in Wahrheit Feierabend. Sie saß da und atmete mit jedem Atemzuge Ruhe und Genuß aus, wie den Duft unsichtbarer Blumen.

»Gott, ja, du hast es gut! Wenn ich jetzt nach Hause komme, muß ich den Andrjuscha erst noch zu Bett bringen. Wobei er neuerdings schreit.«

»Besorgt denn nicht das alles eure Kindsfrau, Tante Ottilie?« fragte Cita und schälte der Tante eine Orange.

»Ich verlasse mich nicht gern auf sie, -- ich muß immer alles selbst thun. Aber übrigens wär es zu undankbar, wenn ich klagen wollte. Nein, das sind ja so süße Pflichten. Man reibt sich gern für sie auf. Man ist für sie auf der Welt.«

»Du bist auch eine der gewissenhaftesten Mütter, die es gibt,« bestätigte die Mutter. »Und solche haben stets zu thun, selbst bei ausgiebigster Hilfe, -- können eigentlich nie sagen: nun ruh ich mich aus.«

»Ja, siehst du: so, ganz so ist es, das behaupte ich immer!« rief ihre Schwester, ordentlich lebhaft, und lockerte ihre Hutbänder.

Bis unter den Hut lag ihr dunkelblondes Haar glatt von der Stirn zurückgestrichen, volles weiches Haar wie Mariannens, jedoch stärker ergraut als bei dieser, obwohl Ottilie um ein Jahr jünger war.

Marianne löschte zerstreut die kleine Spiritusflamme unter dem Kaffeekocher aus und füllte die flachen Täßchen. Ihre Gedanken schweiften unwillkürlich weit zurück in eine Zeit, wo auch sie noch ihre Kleinen zu Bett zu bringen, zu baden, zu füttern, zu besorgen hatte --.

Solch kleiner Nachwuchs, wie ihn Ottilie zu eigen besaß, das war doch etwas Köstliches. Köstlich das Heranwachsen, aber köstlich auch die Kleinen -- --.

»Mein Mann reist nächstens nach Petersburg,« sagte die Schwester, »-- natürlich kein Gedanke, daß ich ihn begleiten kann. Nun, damit find ich mich schon ab. Bis meine Inotschka ganz erwachsen ist, ist es für mich überhaupt nichts mit geselligen Freuden. Aber ihr wünschte ich wohl, daß sie nicht nur Moskauer Kaufmannskreise kennen lernt.«

Sophie rief: »Ach, inwiefern soll es dort besser sein? Ich habe Moskau gern. In Petersburg ist man weder im Auslande, noch in Rußland. Schrecklich lange Straßen, und was für ein Nebel --!«

»Tante Ottilie hat ganz recht,« bemerkte Cita, »dort ist man wenigstens in Europa! Man weiß wenigstens ungefähr, welches Jahrhundert man eigentlich schreibt, während hier --«

Tante Ottilie nickte.

»Ja, man merkt es an allem: nicht nur, wenn man geistige Bedürfnisse hat, sondern auch wenn man einen modernen Kleiderstoff kauft,« bestätigte sie, »dort ist alles: die Newa, der Hof, alles Offizielle und überhaupt alles, was gilt. Wir sind hier wie zurückgeblieben. Die Russen haben überhaupt was Zurückgebliebenes.«

»Gar nicht alle. Etwa Tomasow?« meinte Sophie.

Cita mußte lachen.

»Nein, der ist aber auch wirklich der einzige!« gab sie zu. »Wirklich der einzige, auf den ich mich freute. Ein Glück, daß der unser liebster, nächster Freund ist.«

»Nun, nun! Von Haus aus doch einfach euer Arzt,« dämpfte die Tante, aber Sophie unterbrach sie lebhaft: »Ach, da bist du aber schief gewickelt! Wenn wir gesund sind, brauchen wir ihn noch viel mehr, nicht wahr, Ma?«

Die Mutter blickte auf.

»Sprecht ihr von Tomasow? Ja, lieber Himmel, was sollten wir ohne ihn wohl anstellen?«

Ihre Schwester warf ihr einen zurückhaltenden Blick zu.

»Aber, liebste Marianne! Das heißt doch wohl ein wenig übertreiben.«

Ma sagte sanft: »Nein, es ist kaum übertrieben. Das kann nur ich allein beurteilen. Es ist ja so alte, uralt gefestete Freundschaft. Sie stammt aus der allerersten Zeit meines Zurückkehrens hierher. Die Kinder waren damals sechs und sieben Jahr alt. Zähl selbst.«

»Ach ja, Marianne, das weiß ich. Aber das Wichtigste ist ja doch gewesen, daß er dir als Arzt aushalf. Daß er dir half, dein Leben genau zu regeln. Damals, als du dich gleich so schrecklich überanstrengtest. Und wenn er dir dann vielleicht auch noch manche gute Beziehungen verschafft hat --«

Ma machte eine leise abwehrende Handbewegung.

»Laß das,« bat sie, »was du da nennst, ist das ganz Aeußerliche. Und über das andre kann ich nicht sprechen. Nicht, ohne es zu profanieren.«

Tante Ottilie hatte ihr allerverschlossenstes Gesicht.

»Wirklich, Marianne, ich begreife manchmal gar nicht, wie du nur sprichst! Du, die so ungeheuer selbständig ihr Leben in die Hand genommen hat, -- die sich mit solcher Energie und aus eigner Kraft behauptet hat, -- wie sprichst du mitunter nur? Ganz wie irgend eine kleine unselbständige Frau, die andern alles verdankt, und der andre zu allem verhalfen. Nun, weißt du, _wenn_ das so ist --«

»-- Es ist so,« sagte Ma lächelnd.

»Ja, dann muß ich dir sagen: dann braucht sich auch unsereins neben dir gar nicht so gering vorzukommen, denn schließlich: unser Stück Arbeit thun wir auch im Leben.«

»Ja gewiß, du Liebe!« meinte Marianne, und sie lachte.

»Aber wir schwärmen nun einmal für Doktor Tomasow,« erklärte Sophie, im Drang, ihre Tante zu bekehren, »er ist ganz außerordentlich gescheit, mußt du wissen.«

»Ja, das ist er,« bestätigte Cita nachdrücklich.

»Das ist noch eine recht zweifelhafte Tugend,« meinte die Tante etwas kühl, »aber für euch Kindsköpfe, die ihr es in dem Punkt noch seid, braucht ja wohl ein Mensch nur gelehrt oder gescheit zu sein, damit ihr ihn in einer Weise anbetet -- --!« Sie hob die Augen ironisch zur Zimmerdecke.

Cita stand brüsk auf.

»Du kannst mir einfach leid thun, Tante Ottilie!« äußerte sie mit einem vielsagenden Achselzucken, das nicht eben artig ausfiel. Und sich demonstrativ abwendend, horchte sie hinaus, wo es grade geschellt hatte.

Ihre Tante war dunkelrot geworden, doch hielt sie an sich, nur ihre Augen zeigten einen erhöhten, stählernen Glanz.

Sie sah über Cita hinweg auffordernd auf deren Mutter.

»-- Ja, -- ich weiß wirklich nicht, Marianne, -- gestatten deine Erziehungsgrundsätze diesen Ton --?« bemerkte sie fragend, und ihre Haltung wurde gemessner.

Aber in diesem Augenblick hatte auch Marianne nach dem Vorflur hingelauscht.

Man hörte, daß die Wohnungsthür wieder geschlossen wurde, eine halblaute Frage, ein Räuspern --

»Das ist Doktor Tomasow!« rief Sophie.

Sie lief hinaus.

Tante Ottilie hatte sich bereits von ihrem Pferdejochstuhl erhoben.

»Aber liebe Ottilie! Du wirst doch nicht deshalb fortgehn --?«

»Gewiß nicht, meine gute Marianne; du vergißt nur, daß ich bloß auf einen Sprung kam und eilig bin, -- auf ein andermal also,« sagte die Schwester etwas gezwungen und verabschiedete sich kaum merklich von Cita.

»Nun, wie du willst. Komm, laß uns durchs Wohnzimmer hinausgehn, -- sieh, da könnten wir so gut plaudern, denn die Kinder, die schleppen jetzt unsern Doktor in den ›Spalt‹ hinein; ich wette, sie gießen ihm noch den kalten Kaffeerest ein.«

Den Arm um Ottiliens Schulter, ging Marianne langsam durch das Wohnzimmer, das nur durch eine Lampe mit dunkelgrüner Glaskuppel vom Schreibtisch her erhellt war. Die Thür zum »Spalt« hatte sie zugedrückt.

»-- Nun --? Stört dich der Doktor hier nicht mehr?«

»Ach, an den dachte ich eben wahrhaftig nicht! Was mich drückt und erstaunt, ist etwas ganz andres --;« Ottilie blieb mitten im Zimmer stehn, und die Schwester groß anblickend, fügte sie mit betonter Langsamkeit hinzu: »Du läßt dir deine Töchter über den Kopf wachsen, meine arme Marianne.«

Marianne lachte leise und schelmisch, sie ergriff die Schwester am Arm und schüttelte sie in heiterm Zorn: »O du Böse, -- du Böse! Kannst du denn nicht dem Mädel ein unachtsames Wort vergessen? Gewiß, sie hätt es nicht so sagen sollen. Aber treffen und verwunden kann unsereinen doch nicht dieser kleine schwache Pfeil --? Ein Pfeil aus solchen jugendlich heftigen, jugendlich übereifrigen Händen?«

»Du hättest es aber rügen müssen. Darum allein handelt es sich nur.«

»Rügen -- sofort? Vor dir? Meine einundzwanzigjährige Tochter um einer Bagatelle willen vor euch demütigen? Nein, wie magst du das nur sagen, Ottilie! Du mußt auch nicht vergessen, daß Cita längst --«

»Längst im Auslande studiert! Ja ja, das weiß ich! Das ist grade das Unglück. Und ist sie erst ›Doktor‹, -- mein Himmel, dann darf sie wohl vollends thun, was ihr beliebt,« fiel ihr Ottilie nervös ins Wort.

Marianne schüttelte verneinend den Kopf.

»Ich meinte jetzt eben nicht grade: weil sie im Auslande studiert. Ich meinte nur: weil sie in so vielen Beziehungen schon fest und tüchtig dasteht und jedes Vertrauens würdig, wie ein reifer Mensch,« sagte sie warm und mit ruhigem Stolz.

Ihre Schwester seufzte. Sie band die Hutbänder zu und wandte sich zum Gehn.

»Fruchtlos, mit dir zu streiten, Marianne. Wir einigen uns doch nicht. Ich sehe den Fehler zu deutlich: du gehst immer zu weit in allem, -- das thatest du immer. Alles packst du mit solch innrer Leidenschaft an, gibst dich so ganz dran! Es war auch mit deiner Ehe nicht anders, glaub ich, --«

»Da glaubst du recht!« antwortete Marianne sehr leise, und in ihre Augen trat ein dunkles Leuchten.

»Und die Folge?! Nun, ich will nicht drüber sprechen. Aber daß du so ganz zerbrochen am Boden lagst, -- diese gräßliche Zeit. Man kann das doch nicht einfach Witwentrauer nennen --. Und jetzt mit deinen Töchtern. Sie gehn dir buchstäblich über alles. Sind dir dein ganzes Mark und Blut.«

»Ja, Ottilie. So ist es. Soll es denn nicht so sein?«

Ottilie hatte schon den Griff der Thür nach dem Vorflur gefaßt. Sie ließ ihn noch einmal los, wandte sich der Schwester voll zu und sagte halblaut: »Nein! Nein, -- siehst du, das ist es eben: es soll nicht so sein. Man muß die Dinge nicht so bis auf den Grund auskosten. Man muß sich zurückhalten, sonst ist man verloren. Sonst verliert man jeden Halt.«

»O du! Das wäre eine traurige Lehre! Man lebt ja nicht, es sei denn, um sich hinzugeben. Man lebt ja nur soviel, als man liebt.«

Marianne sagte es inbrünstig.

Hinter der Thür zum Spalt hörte man Scherzen und Lachen. Ein Durcheinanderreden von Russisch und Deutsch.

Ottilie entgegnete mit gesenkter Stimme und einem Anflug von Bitterkeit: »Das ist kein Ding wert. -- -- Und wer sich dermaßen ausgibt, verflacht mit der Zeit. Was behält er dann noch Unangetastetes, Eignes? -- -- Aber geh jetzt, bitte, zu den andern hinein. Sie warten drinnen auf dich.«

»Sie warten nicht. Ich gebe dir deinen Pelz um,« bemerkte Marianne und geleitete die Schwester hinaus. In ihren Gedanken weilte sie jedoch noch beim Gespräch. Sie hätte rufen mögen: »Ein Ding ists wert: die Kinder! Warum sie nur erziehen? Warum nicht von

Grund aus sich freuen und jubilieren über sie? Frage deine Tochter! -- sie hätt es bei mir seliger als bei dir --.«

»Grüße mir Inotschka!« sagte sie nur.

»Die wird nur rot, wenn ich ihr das bestelle. Ueber alles wird sie rot. Es ist wirklich schon fast ihre einzige Sprache, -- und dabei kann sie drei Sprachen so gut. -- -- Willst du nicht vielleicht morgen abend den Thee bei uns nehmen, wenn du vom Unterricht kommst? Du hast es schon lange nicht gethan. Wir sehen uns wahrhaftig fast nur, weil du Montag Nachmittags mit Nikolai lernst.«

»Ja, ich will kommen,« meinte Marianne. »Am Sonntag kann ich ja ausschlafen.«

Sie küßten sich, und Ottilie ging.

Nachdenklich blieb Marianne im Vorflur stehn. Sie blickte zu Boden, als suche sie etwas. Sie suchte, sich in ihrem Innern auf etwas zu besinnen.

Wie sagte doch Ottilie? »Sonst verflacht man mit der Zeit.« Es gab Leute, die hielten Ottilie für »tief«. Das war es also. Sie gab sich nicht aus, lebte einfach mit Dreivierteln ihrer selbst, -- vielleicht nicht einmal damit --.

Aber war es denn immer so gewesen? Nein, sicher nicht. Einst, als Kinder, hatten sie einander viel stärker geglichen als jetzt, hatten gemeinsam und gleich empfunden. Erst viel später mußte die Schwester ihr Temperament außer Gebrauch gesetzt haben, -- es beiseite gelassen, -- es »reserviert« haben --, wofür? Und wie, in aller Welt, machte man das? -- --

Marianne war ins Wohnzimmer zurückgegangen und setzte sich vor das geöffnete Pianino, worauf Sophiens Geige lag.

Zerstreut, ganz leise schlug sie ein paar Töne an.

Sie dachte an Inotschka. Ach, der würde sie sich auch gern hingegeben haben. Die würde sie gern zu ihren Schülerinnen gezählt haben.

Aber sie fühlte selbst, daß es nicht anging. Auch wider Wissen und Wollen hätte sie jeden Augenblick ihren Einfluß dem der Eltern entgegengerichtet.

Inotschka, halberwachsen, noch mager, mit ihren allzu ernsthaften Augen und einem so weichen Munde, einem so kußbedürftigen weichen Munde, blieb vor ihrer Phantasie stehn, während sie die leisen, dunkeln Töne anschlug -- --.

Darüber merkte sie gar nicht, daß sich die Thür zum Spalt öffnete.

Beide Mädchen und Doktor Tomasow drängten sich geräuschlos in den Rahmen der Thür.

Und da weckte ein fröhliches Gelächter Marianne aus ihrem Sinnen. Sie schaute sich um. Alle drei standen sie da und lachten sie aus.

Sie lachte ohne weiteres mit.

»Kommt nur herein. Tante Ottilie ist fort,« sagte sie.

Vor Tomasow sprach sie stets deutsch, wie mit den Kindern untereinander.

»Ja freilich! Die ist lange fort. Aber was verstecktest du dich denn vor uns, Ma? Dürfen wir deine geheimen Gedanken gar nicht wissen, aus denen wir dich herausgelacht haben?« fragte Sophie neckend.

»Jawohl. Ich dachte darüber nach, warum ich euch gutwillig mir dermaßen über den Kopf wachsen lasse, ihr Kinder,« entgegnete Marianne, und sie reichte dem Freunde die Hand zum Willkommen.

Sophie schlug entrüstet die Hände über dem Kopf zusammen, Cita aber erkundigte sich interessiert: »-- Nun, -- und das Ergebnis war, Ma --?«

»Es war: Wachset nur, -- wachset!« sagte Marianne lachenden Mundes, und ihre Augen strahlten gütig.

Doktor Tomasow blickte unter halb gesenkten Lidern nach ihr hin. Sein bartloses Gesicht, das so offen jede Falte und Furche in den Zügen des hohen Vierzigers zur Schau trug, war in Bezug auf seine stummen Gedanken nicht plauderhaft. Hager, mit slavisch kurzer Nase und energischen Kinnlinien, -- dem Grundriß nach ein russisches Barbarengesicht, war es vom Leben verarbeitet,

vergeistigt, aber im Ausdruck wie verschlossen worden. Kurz, dicht und früh ergraut, wellte sich das Haar über der freien Stirn fast ganz grade empor.

Die beiden jungen Mädchen mußten ihn gut kennen. Als er sich nicht in ihr Scherzgespräch mit der Mutter mischte, blickten sie einander flüchtig an und zogen sich dann einmütig in ihr Zimmer zurück, -- in Sophiens eigenstes Reich, das, über den Gang hinaus, nach dem Hofe zu lag, und wo jetzt Cita wohlgelittener Gast war.

Die Mutter sah ihnen nach, wie sie, nach einigen heiter gewechselten Worten, fortgingen: Cita mit ihrem festen, gleichmäßigen Schritt voran, und hinter ihr Sophie, die sich noch einmal mit einer graziösen Wendung umsah und lächelte.

Als sich die Thür hinter ihnen schloß, hob Marianne ihre Augen zu Doktor Tomasow.

»Nicht wahr, die Sophie ist schmal in den Schultern? Sie hustet.«

Er antwortete ruhig: »Das thun wir hier alle mehr oder minder zu dieser Jahreszeit. Sie sind mit dem Kinde etwas zu ängstlich, Marianne.«

»Ja, sie erinnert mich so an -- --, auch er war zart.«

Und da sie einen zaudernden Ausdruck in Tomasows Gesicht wahrzunehmen wähnte, trat sie ganz dicht auf ihn zu.

»Tomasow! Wenn -- nein, wenn --, Sie dürfen mir nie etwas verschweigen, nie --.«

Und sie erblaßte plötzlich.

»Aber! Aber!« sagte er mit seiner überredenden eindringlichen Stimme und nahm ihre Hände, wie die eines Kindes, in die seinen. »Verbieten Sie ganz harmlosen Dingen, mit Ihnen gleich so durchzugehn, wie wildgewordene Pferde. -- -- Ganz kalte Hände haben Sie auf einmal bekommen. Kälteres Blut wäre besser. -- -- Also: Sophie ist absolut gesund. Ich bürge Ihnen dafür. Die Aehnlichkeit, die Sie da eben andeuteten, beschränkt sich auf die zarte Hautpigmentierung, die mit so blondem Typus zusammengeht, -- sie garantiert Sophie auf lange hinaus einen blendenden Teint, bei etwas Pflege. Nun, hübsch genug ist sie schon jetzt, dächt ich. Ein liebes, gutes, schönes Kind haben Sie an ihr, Marianne.«

Sie hörte ihm aufmerksam zu, unendlichen Glauben in den Augen.

Seine Gestalt, obwohl in den breiten Schultern unmerklich geneigt, überragte sie um ein gutes Stück. Sie erschien nicht mehr mittelgroß, sondern fast klein, und wenn sie beim Sprechen die Augen so zu ihm heben mußte, konnte man den Altersunterschied zwischen ihnen für beträchtlicher nehmen, als er in Wirklichkeit war.

»Aber gut ist es für Sophie, daß sie bei mir ist, und ich für sie sorgen kann, bis in jede Geringfügigkeit, -- das finden Sie auch? Cita ist ja so vortrefflich aufgehoben in der Familie, bei der sie in Berlin wohnt, -- ich korrespondiere ja auch mit den Leuten, -- und doch, -- für Sophie wäre das nichts --.«

Sie sah ihn dabei fragend an.

Tomasow zuckte die Achseln.

»Natürlich würde sie es nirgends in der Welt auch nur annähernd so gut haben, wie bei ihrer Mutter. Indessen, das ist doch selbstverständlich. Warum fragen Sie erst danach?«

»Ich weiß es nicht,« murmelte Marianne; »ich weiß nicht, warum sie mein Angstkind ist. In meiner Liebe zu ihr ist so viel Angst --. Darum muß ich manchmal von Ihnen hören, daß sie Ihnen keine Sorge macht.«

»Nein. Die machen höchstens Sie mir von Zeit zu Zeit, kleine Ma,« sagte er mit leisem, fast nachsichtigem Lächeln und gab ihre Hand frei.

Er nannte sie gar zu gern mit diesem Namensstummel, der daraus entstanden war, daß sich die Kinder in der Kindheit bisweilen herausgenommen hatten, die Mutter wie einen guten Kameraden »Marianne« zu titulieren, was Tomasow schon damals äußerst bezeichnend fand. Hin und wieder ließ jedoch das Erstaunen andrer sie mitten in diesem Unternehmen stecken bleiben. Zuletzt blieb von Mariannens Namen nur das übrig, was ein guter Wille auch als Anlauf zu dem Wort »Mama« nehmen konnte.

»Und die Einzigkeit der Silbe paßt zu ihr,« dachte Tomasow bei sich, »-- dieser einzige Ton als Name, -- es ist, wie wenn man etwas nur eben intonierte, was man nicht ganz nennen will, noch auch äußern kann. Weit, weit hinter dem einzelnen Ton ruht und klingt das Ganze --.«

Marianne war zum Schreibtisch getreten und schraubte die Lampe höher.

»Stehn Sie mir da noch immer im Rücken? Das ist ja unheimlich,« sagte sie, den Kopf nach Tomasow zurückwendend, und dann ließ sie sich müde vor dem Schreibtisch in dem alten Luthersessel nieder, der noch von ihrem Vater, dem Schuldirektor, stammte.

Tomasow zog sich den langen Schaukelstuhl neben der Blattpflanzengruppe ein wenig näher zu ihr heran.

Er nahm von den Zigaretten, die Marianne ihm anbot, und zündete sich schweigend eine an.

»Ich glaube, speziell dafür bin ich am Ende auch das letzte Mal vom Auslande wieder heimgekehrt, ein so schauderhafter Kosmopolit ich auch schon zu werden drohte,« bemerkte er dann.

»Wofür? Für die Plauderecke?«

»Es ist nicht einmal eine Plauderecke, streng genommen, denn wir sind oft ziemlich wenig redselig, besonders wenn Sie abends müde sind oder gar anfangen, Notizen in Ihre schrecklichen blauen Schulhefte zu machen.«

Marianne lehnte sich zurück und kehrte ihm das Gesicht zu. Sie sagte lächelnd: »Nun, dann sitzen Sie eben und freuen sich drüber, wie unendlich brav und artig ich bin. Denn das muß ja doch eine Freude für Sie sein! Wer hat mich denn gelehrt, diese Schulheftexistenz auszuhalten.«

»Ich etwa?!« Tomasow machte eine ungläubige Miene. »Ich habe Ihnen wohl im Gegenteil alle Schwierigkeiten und Schrecknisse einer solchen klarzumachen gesucht, als Sie sich in den greulichen Kampf stürzten.«

»Ja. Und mich dadurch für ihn gewappnet, -- mich dadurch gelehrt, nicht gleich beim ersten Ermatten zu erliegen. Ich wußte so bestimmt: Sie stehn da und helfen mir immer wieder auf, -- ach, das war ein gutes Gefühl, glauben Sie mir.«

Tomasow rauchte schweigend.

Ganz so war es wohl nicht. Er hatte in Wirklichkeit ihren Kräften nicht den Existenzkampf zugetraut, den sie so löwenmutig für sich und ihre Kleinen vollbracht hatte. Nein, ursprünglich hatte er ganz und gar nicht annehmen können, daß sie einem derartigen Leben gewachsen sei.

Er half ihr damals mit seinem Rat und Beistand gleichsam nur so vorläufig. Er half ihr, um ihr nah bleiben zu können.

Jedoch dann -- später -- wenn sie doch am Ende ihrer Kräfte sein würde, die sie bis zum Zersprengtwerden anspannte, -- ja, damals dachte er sich dann ein ganz andres Ende. Ein völlig andres --.

Fast ohne daß er es wußte, fixierte Tomasows Blick bei dieser Erinnerung den geschlossnen Olivenholzrahmen, der in der Mitte des Schreibtisches stand.

Marianne war der Richtung seines Blickes gefolgt.

»Darf ich?« fragte er.

Sie streckte, ohne zu antworten, die Hand aus, nahm den Rahmen vom Tisch und reichte das ihm wohlbekannte Bild herüber.

Er schaute aufmerksam auf das junge beseelte Gesicht im Rahmen, -- ein bartloses Jünglingsgesicht. Eine Aehnlichkeit mit Sophie war in der That unverkennbar, nur nicht in der Kühnheit der Stirn und des Kinnes.

Aber etwas so Zartes lag über dem Ganzen --.

Tomasow bückte sich tiefer über das Bild und bemerkte: »Wenn ich mir vorstelle, wie Sie damals ausgesehen haben müssen, -- und wie dieses hier aussieht, -- so kommt mir leicht das Gefühl: sieh da, zwei Kinder, die man schützen möchte.«

Sie lächelte unmerklich.

»Wir brauchten keinen Schutz. Gegen nichts. Wir hatten ja einander.«

»Zugegeben. Aber wer von Ihnen schützte wen?«

»Jeder den andern. -- Ach, es ist nur eins nicht zu fassen: daß der eine zurückbleibt, wenn der andre geht. Wie mag denn das nur möglich sein? -- -- Arme Menschen, daß es so ist.«

Er erhob sich, um das Bild auf den Schreibtisch zurückzustellen.

»Keine solchen Worte, Marianne! Keine solchen Aufwallungen, auch nicht für Sekunden! Sie haben an sich selbst erfahren, daß das Leben immer wieder neu keimt.«

»Ja, das Leben: das heißt meine Kinder.«

Tomasow nahm wieder Platz im Schaukelstuhl. Nach einer Pause, in der er schweigend vor sich hinrauchte, sagte er langsam: »Mir hat es doch immer scheinen wollen, als ob in Ihnen ein starkes Bedürfnis ist nach einer Ueberlegenheit neben Ihnen, -- nach jemand, zu dem Sie aufblicken. Sie haben so viel vom Kinde irgendwo in sich, Marianne. -- Daher kann ich Sie mir vielleicht so schwer an der Seite -- an ›seiner‹ Seite vorstellen.«

Sie lehnte in ihren Stuhl tief hineingeschmiegt und starrte wie gebannt auf den Rahmen. Auf ihren Wangen lag ein leichtes Rot.

»O über uns beiden war ja so viel -- über uns beiden!« sagte sie mit halber Stimme. »Wozu noch eine andre Ueberlegenheit? Wir wandelten, ineinander geschlungen, gemeinsam unter so hohen Träumen, so hohen Zielen entgegen. Und ich meine immer: was wir da lebten, nur das ist Leben. Von allen Seiten wölbte es sich um uns wie ein Himmel, dem gaben wir uns anheim. Und so war uns jede Krume Erde eine Heimat.«

Tomasow dachte wieder: »Wie zwei Kinder.« Doch erwiderte er nichts.

Aber Marianne wendete ihm den Kopf zu, und plötzlich streckte sie ihm die Hand entgegen: »Sie urteilen nach später,« bemerkte sie, »ja, da brauchte ich allerdings jemand über mir, brauchte Rat und Hilfe und Halt. -- Einen Halt in der vollkommnen Heimatlosigkeit, eine Orientierung in der vollkommnen Fremde. -- -- Da brauchte ich _Sie_. Ich konnte nicht allein sein, so ganz allein im Finstern. -- Und ich denke auch jetzt oft: meinetwegen das Allerbitterste überwinden, wenn nur eine warme menschliche Stimme dazu überredet, es befiehlt, anbefiehlt. -- Ich weiß nicht, ob alle Frauenherzen so schwach sind. Ich bin es.«

Er hatte ihre Hand entgegengenommen und hielt sie, darauf niederblickend, einen Augenblick in der seinen. Ganz leicht strich er mit den Fingern über ihren Handrücken hin, der ein wenig rauh geworden war vom Wind und der Kälte dieser Wochen, die Marianne unausgesetzt auf die Straße trieben.

Er wußte, daß sie einen nervösen Widerwillen gegen rauhe, gerötete Hände oder aufgesprungene Lippen besaß. Als sie jung und glücklich war, da mußte sie sich gewiß, selbst unter schmalen äußern Verhältnissen, mit Entzücken gepflegt haben, wie ein schöner Mensch vor einem Fest.

Tomasow ließ Mariannens Hand sinken und stand auf.

»Was ist Ihnen denn? Sie wollen doch nicht schon gehn? Warten Sie noch ein wenig, und am besten: bleiben Sie zum Thee,« schlug Marianne vor, »Sophie wollte Ihnen so gern ihre Fortschritte im Geigenspiel vorführen, -- mögen Sie? Dann machen Sie ihr die kleine Freude.«

»Ja, warum nicht?«

Tomasow war ans Fenster getreten und schaute vor sich hin.

Marianne öffnete die Thür nach dem Gang, rief dem Mädchen etwas zu und kam dann wieder zu ihm.

»Was schauen Sie denn so unverwandt an?« fragte sie und trat dicht an ihn heran.

Er zuckte die Achseln.

»Ich betrachte mir nur, was da in Reih und Glied zwischen den Doppelscheiben im Fenster aufgestellt ist,« entgegnete er und deutete auf eine Anzahl verdeckter Glasbehälter, »wie Soldaten mit Papierhelmen auf dem Kopf. Finden Sie diese Dinger nicht häßlich?«

»Sie sind nur häßlich, bis sie blühen. Dann kommen sie ins Zimmer, und die Papierkappen kommen fort. Und dann sind es Hyazinthen!« sagte sie tröstend, mit einem Lächeln.

Aber Tomasow war verstimmt.

»Hyazinthen? Wozu denn? Mögen Sie etwa diesen allzusüßen Duft? Es sind doch nicht am Ende gar Ihre Lieblingsblumen, Marianne?«

»Lieblingsblumen? -- Rosen hab ich schon lieber, -- und am liebsten, wissen Sie was? -- am liebsten besäße ich ein ganzes Treibhaus und einen Wintergarten dazu!« meinte sie schelmisch. »Solche Hyazinthe unter ihrer Papierkappe ist nun eben mein Treibhaus. Man muß sie nicht allzudicht unter die Nase halten, sondern die Gläser im Zimmer gut verteilen, dann geht es schon. -- Frühling und Duft ist es ja doch! Und ganz ohne die beiden mag ich so wenig sein, wie ganz ohne Musik.«

»Wegen der Hyazinthen werden ja hier die Doppelscheiben im Winter nicht eingeklebt, wie die übrigen,« bemerkte Sophie, die hereingekommen war und nach ihrer Geige suchte.

Tomasow zündete sich eine frische Zigarette an und setzte sich in der Nähe des Fensters nieder. Er betrachtete Marianne.

»Wie viel Genußfreudigkeit ist doch in ihr. Selbst jetzt noch!« dachte er. »Unausgegeben, aufgestaut! Köstlich müßte es sein, das zu lösen, zu befreien. Selbst jetzt noch.«

Sie saß wieder auf ihrem frühern Platz, den Kopf ein wenig geneigt. Während sie darauf wartete, daß Sophie die Kerzen am Notenpult anzünden und beginnen sollte, schien sie vor sich hinzuträumen, -- vielleicht in Gedanken, die das kurze Gespräch mit Tomasow über ihr Eheglück vorhin in ihr geweckt haben mochte. So kam es ihm vor.

Etwas sehr Sanftes lag über ihren Zügen, ein Abglanz, wie aus der Jugend. Für die Mutter der beiden großen Mädchen hätte man sie in diesem Augenblick kaum gehalten.

Cita war leise eingetreten und stand noch an der Gangthür, um die ersten Geigentöne nicht zu stören. Auch sie schaute zu Marianne hinüber, und dabei kam auch ihr in den Sinn, wie schön ihre Mutter sei, -- wie so sanft und schön sie doch jetzt eben aussehe.

Es berührte sie mit einem warmen kindlichen Stolz. Ihre dunkeln Augen erglänzten vor Freude.

In einer Pause des Spiels trat sie von hinten an Mariannens Stuhl heran. Und mit einer ihrer spontanen, unvermittelten Bewegungen umschlang sie die Mutter und küßte sie in den geneigten Nacken.

Dabei kehrte sich Cita halb gegen Tomasow, dessen Blick unverwandt auf ihrer Mutter ruhte. Cita sah unwillkürlich, mit einem hübschen Ausdruck, zu ihm hinüber, als wollte sie, an Marianne geschmiegt, entzückt sagen: »Wie lieb und schön sie ist, nicht wahr? Möchte man sie nicht auf dem Fleck totküssen?!«

Da verdüsterten sich plötzlich ihre Augen.

Irgend eine unerklärliche Befangenheit überfiel sie. Sie bückte ihren Kopf, wie abwehrend, gegen den Kopf der Mutter, und errötete langsam über das ganze Gesicht.

Tomasow hörte inzwischen zerstreut dem Geigenspiel zu. Er liebte und verstand Musik, musikalisch von Natur, wie fast alle Russen, aber heute war ihm nicht nach Sophiens Musik, die noch Nachsicht verlangte.

Ja ja! Daß die Kinder da waren, das hatte Marianne so unzugänglich erhalten und so vorzeitig ernst gemacht. Es machte sie bisweilen ergreifend schön, dies Ernstsein tief unter aller Heiterkeit, jedoch zu ernst, -- allzu ernst für ihn --.

Tomasow begegnete bei dieser Erwägung Citas Augen, die ihn forschend anzusehen schienen. Sie stand noch an den Stuhl der Mutter gelehnt, als schütze sie ihn.

»Wie ein kleiner Polizist!« dachte Tomasow bei sich.

Aber zugleich gestand er sich, daß diese Kinder es allein gewesen waren, die einst Marianne die Fähigkeit zum Leben wiedergegeben hatten.

Ursprünglich schien der gewaltsame Schmerz um den toten Gatten auch die Mutter in ihr getötet zu haben. Als man sie nach Rußland brachte, -- mit ihren beiden allerliebsten kleinen Dingern, -- da war sie nicht bereitwillig, weiterzuleben. Sie konnte nicht leben. Und in der Verwandtschaft begann man, von Geistesstörung zu sprechen und von Ueberführung in eine Heilanstalt.

Damals, während dieser ersten furchtbaren Verzweiflungszeit ihres Schmerzes, sah Tomasow Marianne zum erstenmal.

Er selbst kam grade verstimmt aus dem Auslande. Nach Jahren anregenden Genusses und interessanter Arbeit in Wien und Paris, erschien ihm zu Hause alles so schal und abgestanden, so gänzlich regungslos. Und am wenigsten spürte er Lust, sich hier wieder dauernd in seine ärztliche Praxis einzugewöhnen.

An einem dieser Tage wurde er zu Marianne hineingeführt.

Auf dem Boden ihres Zimmers kauernd, das braune Haar dicht und wirr um ihr armes Gesicht, -- das Gesicht eines fassungslos leidenden Kindes, -- ganz stumm und sehr abgemagert, denn sie weigerte sich, Nahrung zu sich zu nehmen: so sah er sie zum erstenmal.

Was ihn betroffen machte und fesselte, von allem Anfang an, das war die Stärke dieses Temperaments, das gegen den Tod anstürmte, ihm innerlich fortwährend seine Beute abzujagen schien. Nie, meinte Tomasow, ein Gleiches an Seelenkampf geschaut zu haben, -- an Kampf gegen das Unentrinnbare, -- wie er jetzt Tag um Tag vor sich sah, seitdem er begonnen hatte, Marianne seine ärztliche Pflege zu widmen.

Ihre Verwandten bedauerten sie aufrichtig, aber ihnen war von Beginn an die Ehe verrückt vorgekommen. Beide Gatten so blutjung, beide noch kaum reif für den großen Jubel und den großen Ernst, den sie vom gemeinsamen Leben erwarteten, -- und der junge Künstler noch keineswegs genügend zu Geld oder zu Ruhm gelangt, als er um Marianne warb. Daß er auch dazu, wie zu allem, eben ihrer Nähe bedurfte, verstanden die vernünftigen Leute nicht. Und er durfte sie auch keines Bessern belehren, denn als es ihm eben gelingen wollte, mußte er schon sterben.

Das jedoch war wiederum Marianne unfähig zu verstehn, -- nein, nie und niemals vermochte sie es zu fassen, daß das Leben wider ihren liebsten Menschen sein konnte, daß es ihn sterben lassen, -- ihn im Stich lassen konnte.

Auf Tomasows Rat kam Marianne aufs Land. In einem Dorf bei Moskau bezog eine alte Verwandte mit ihr ein kleines Landhaus, dicht neben einem verwilderten Park gelegen, der zu einer ehemaligen Privatbesitzung gehörte.

Es wurde grade Frühling, -- später nordischer Frühling. Unendliche Ebenen im ersten Ergrünen, weite knospende Birkenwälder, ein stiller baumumstandener See --.

Dort in der Einsamkeit, dort im Frühling, dessen sanfte Schönheit ihr bis zu Tode wehe that, und der ihr mit seinem Zauber die Seele blutig riß, tobte sich für Marianne das Schwerste rückhaltlos aus.

Sie gesundete vielleicht aus der nämlichen Kraft heraus, aus der sie gelitten hatte, -- sie durchkostete ihren Schmerz viel zu stark und inbrünstig, um sich nicht eines Tages auch selbst von ihm zu heilen.

Von der Veranda des Landhauses führte ein primitives Holzbrückchen, über etwas morastiges Wassergerinsel geschlagen, direkt auf die grasbewachsenen Wege des alten Parks. Unzählige Mückenschwärme durchsummten ihn im Sommer und hielten beständig einen feinen dunkeln Ton in der Luft fest; warm und feucht stieg von den schattigen Wiesen der Duft über üppig verwilderten Blumen auf, und hier und da stand eine zusammengebrochene, bemooste Steinbank an lichte Birkenstämme gebaut. Hier hinaus fuhr Tomasow jeden Tag. Wenn er kam, pflegten ihm die beiden kleinen Mädchen schon entgegenzulaufen, Annunciata, die Aeltere, mit muntern großen Sprüngen, und die jüngere, Sophie, die immer zu hastig lief und oft über ihre eignen kleinen Beine stolperte, bis sie endlich der Länge nach und mit bitterm Geschrei bei ihrem Freunde angelangt war.

In der Stadt und in seinen eignen Angelegenheiten beschäftigten Tomasow allerlei komplizierte Sorgen: wie er sich zur Heimat stellen, sich in ihr einleben werde, und warum ihr noch so vieles abgehe, was in den kulturreifern Ländern des Auslandes längst auf der Tagesordnung stand? Aber hier in diesem sommerdunkeln Park, bei Marianne und ihren Kindern, verblaßte ihm regelmäßig die Wichtigkeit aller Kultur- und Geistesfragen. In den Vordergrund trat das Leben in seiner elementarsten, seiner einfachsten Bedeutung, -- das Leben angesichts des Todes und die Frage, ob es zu ertragen sei. Es kam ihm vor, als müsse das Leben etwas Schönes sein, weil er Marianne leise dazu zurückkehren sah, -- ganz leise anfangs, indem sie mit den Kindern zu spielen begann.

Noch ehe sie wieder für sie zu sorgen und zu denken wußte, spielte sie mit ihnen, als sei sie selbst noch nicht viel mehr, als ein schwaches Kind. Und doch hatte sie damit schon die große Frage für sich beantwortet.

Der erste Gedanke, der später ganz von ihr Besitz nahm, war ebenfalls naheliegend und primitiv: der Drang, für das tägliche Brot zu arbeiten. Für den Augenblick war diese Sorge ihr von andern abgenommen worden, -- und im Fall der Not versprach man, ihr auch die Kinder abzunehmen.

Sie wollte mit ihnen zusammenbleiben können, sie selbst ernähren können. Daran erstarkte sie.

Tomasow erinnerte sich gut des entscheidenden Gespräches darüber, an einem unerträglich heißen Sommernachmittag voll Gewitterdrohungen, auf einer Bank im Park. Er ging auf alles ein, was Marianne wünschte, froh, sie überhaupt schon so weit zu haben, daß ihr starke Wünsche und Sorgen kamen. Er erbot sich auch, alle ersten notwendigen Schritte in der Sache zu thun.

Da hob Marianne die kleine Sophie auf ihren Schoß und sich zu Cita niederbeugend, die sich neugierig horchend an ihr Knie drückte, rief sie leise: »Jetzt wird Ma für ihre lieben Kinder schrecklich viel zu thun bekommen! Und je mehr sie thut, desto schöner und größer sollen sie ihr werden, von Tag zu Tage! Ist das nicht herrlich, ihr Kinder?«

Citas kleine Ohren mochten aus den Worten nur den Klang aufgefaßt haben, -- einen so ungewohnt freudigen Klang, daß er an etwas ganz Fernes, Süßes, schon halb Vergessnes mahnen mußte, was einst durch alle Worte der Mutter hindurchgejauchzt hatte, als seien es ebensoviel liebkosende Verheißungen.

So klatschte sie stürmisch in die Hände und sprach der Mutter nach: »Herrlich, ihr Kinder!«

Und in der schwülen Gewitterluft unter den reglosen Bäumen saß Marianne zum erstenmal mit einem Anflug von Lächeln da, wie am Vorabend von bessern, festlichern Tagen.

Tomasow aber dachte fast mit Abscheu an das lähmende, entnervende Arbeitsleben, das nun vor ihr liegen sollte. Und angesichts dieses Lächelns stiegen andre, schönere Möglichkeiten für die Zukunft vor seinen Gedanken auf -- --.

»Unterschätzen Sie nur die Schwierigkeiten der Sache auch nicht allzusehr!« bemerkte er nach einer Pause mit zögerndem Warnen. »Es ist noch nicht sicher, ob Sie so brutalen Anforderungen an Ihre Spannkraft gewachsen sind.«

Marianne hob den Kopf und sah ihm mit zversichtlichem Vertrauen ins Gesicht. Ihre Hand lag auf Citas Haar.

»Daß ich ihnen nicht gewachsen bin, weiß ich wohl!« sagte sie ruhig. »Aber Sie werden mir helfen, über mein bißchen Können hinauszugelangen. -- -- Wollen Sie mir nicht dazu helfen --?«

»Ich will es gewiß, wenn Sie nicht bei näherm Zusehen selbst davor zurückschrecken!«

In Mariannens Augen trat ein Ausdruck wie qualvolle Erinnerung an die überstandenen Seelenkämpfe.

Sie murmelte: »Ich schreckte vor allem zurück, -- vor jeder Minute, weil sie durchlebt sein wollte, -- und war nicht auch das eine brutale Anforderung: -- leben zu sollen --? Ich weiß, daß es mich noch manchmal überkommen wird, -- daß ich dann nicht will, nicht kann, -- ich werde mich gewiß noch oft vor dem Leben fürchten --.« Sie brach ab, ein Schauer ging über sie hin. Dann setzte sie jedoch langsam hinzu: »Deshalb muß jemand mir helfen, der meine Furcht und meinen Widerstand bricht, um der beiden Kleinen willen.«

-- In diesem Augenblick begriff er, wie nah er ihr in der schweren Zeit getreten war als der Unbeteiligte, Unbeeinflußte, der sich ihr ärztlich und menschlich mit strenger Sachlichkeit gewidmet hatte. Er begriff, wie viel sie seiner Hilfe zuschrieb, was zu einem großen Teil die Hilfe ihrer eignen Natur gewesen war.

Ihr sollte er helfen, fortan dem Leben gewachsen zu sein, -- dabei aber lebte er noch sein eignes Leben in unschlüssigem Zwiespalt --.

Und dennoch: er fing an, daran zu glauben, daß es ihm ihr gegenüber gelingen werde. Ein so starker Appell an seine eingreifende, planvolle Kraft ging von diesen ruhig vertrauenden Augen aus, -- eine so starke Freude an der ihm auferlegten Verantwortung weckten sie in ihm, als spannten sich alle Fähigkeiten seiner Seele auf ein Ziel hin.

Und seltsam: gleichzeitig empfand er es noch nie so bitter wie in der Stunde, nicht selber zwiespaltlos und einheitlich, mit voller Thatkraft, im Boden seiner Heimat zu wurzeln. Hätte er nicht schon als Jüngling, -- in jugendlicher Begeisterung zu allem bereit, --

immer nur an die harte, hohe Mauer der bestehenden Zustände stoßen müssen; hätte er nicht erst im Auslande draußen seine volle Entwicklung finden müssen; hätte er, vom Heimweh zurückgezerrt, nicht davon absehen müssen, in seiner Heimat grade diejenigen Einsichten und Fortschritte zur Wirksamkeit zu bringen, deren sie ganz augenscheinlich am dringendsten bedurfte, -- -- wie ganz anders würde sich dann für ihn als Mann, als Mensch, sein Leben zusammengefaßt haben! Wie oft würde es einen ähnlich starken, -- und stärkern Appell an seine Leistungskraft enthalten haben!

Aber davon sprach er nie zu jemand; in der Fremde sprach er von der Heimat nur leise, und dann zärtlich, wie von einem leidenden Kinde, das auch nur anzurühren man Fremden schon verwehrt; und daheim konnte er von seinen Jahren im Auslande nicht mit dem Accent reden, den sie für ihn besaßen, weil hier alle seine Worte unwillkürlich so ausfielen, als sei ihm bloß egoistisches Genußleben gewesen, was ihm dort mindestens ebensosehr als eifriges und ernstliches Arbeitsdasein vorgekommen war.

Er schwieg deshalb, mißtraute den Menschen, und sie vertrauten ihm nicht mehr recht.

-- -- Während er im alten, dichten Park auf der Steinbank unter den Birken saß, schaute er, in solche Gedanken versunken, auf Marianne hin.

Sie blickte gradeaus über die Wiesengründe in die Ferne, den Kopf ein wenig vorgeneigt, die Hände leicht im Schoß gefaltet. Der lose aufgesteckte Haarknoten ließ die sanfte Wölbung der Nackenlinie wundervoll frei.

Kein einziger Zug bewußter Selbständigkeit in der gesammelten Haltung, und doch etwas wie Getrostes --

Es erfüllte ihn mit Erstaunen!

Was ihm auch geschähe: zu allerletzt würde er doch im stande sein, zu einem zweiten Menschen so vertrauensvoll aufzublicken, daß er dessen seelischer Hilfe sich gläubig anheimgab!

Und bei ihr war das im Wiedererwachen zum Leben das erste, -- das Unwillkürliche --.

Das allererste, was sie wiederfand, war eine ruhige, vertrauende Gebärde. -- -- --

=II.=

Draußen herrschte das lustigste Schneetreiben von der Welt.

Den Kutschern und vielleicht auch ihren Gäulen lachte das Herz im Leibe drüber, wie leicht heute die Schlitten über den weißblendenden Boden dahinflogen, der seit etlichen Tagen einer erneuten Schneelage entbehrt hatte, sodaß hier und da bereits das holperige Steinpflaster der unebenen Moskauer Straßen durch den zerstampften und vergrauten Schnee durchzuscheinen begann.

Auch Marianne freute sich, schnell vom Fleck zu kommen. Seit dem frühen Morgen war sie schon so viel herumgetrieben worden, in verschiedene Privatstunden und eine Schule.

Noch ein paar Tage lang! Dann gab es Ferien. Schlossen auch die Anstalten erst kurz vor Weihnachtsabend, so hörte doch der Unterricht in den Häusern meistens schon früher auf.

Marianne kam von weit außerhalb gefahren, wo sich an den Grenzen der Stadt ein großes Mädchenstift befand, nicht allzufern von dem berühmten Jungfernkloster, dessen phantastische Türme herüberwinkten. Auf dem Rückwege von dort ließ sie ihren Schlitten in einer unbelebten, fast ländlichen Vorstadtgegend vor einem einstöckigen, rot angestrichenen Holzhause halten.

Sie stieg aus, bezahlte und ging über den weiten, hellen Hof, den ein einfacher Lattenzaun umschloß, auf eine Wohnung im Erdgeschoß eines Hauses zu, an der sie mit beinah ungeduldiger Freude läutete.

Dies Erdgeschoß war himbeerfarben. Mit rührendem Vertrauen in die Schönheit des Farbigen überhaupt, war hier ein bunter Ton neben den andern gesetzt. Aber das gedämpfte Winterlicht ward zum Künstler an all dem Grellen: es stufte es wunderseltsam ab, bis es aussah, als stünden die bunten Farben da, wie Blumen in einem Strauß.

Hier pflegte Marianne jeden Sonnabend vorzusprechen, wenn sie der Weg vom Stift vorüberführte, mochte die Zeit auch noch so knapp sein. Denn jedesmal bedeutete das für sie inmitten der Arbeitswoche eine sonntägliche Stunde.

Eine ihrer ehemaligen Lieblingsschülerinnen, seit Jahresfrist verheiratet, wohnte hier; eine, die ihr innig zugethan blieb, auch nachdem sie, längst der Schule entwachsen, mit Energie und verblüffender Leichtigkeit Mathematik studiert und es darin zu etwas gebracht hatte.

Die junge Frau öffnete selbst die Thür und bewillkommnete ihren Besuch mit drei schallenden Küssen, einen auf den Mund und je einen auf Mariannens schneenasse Wangen. Dann nahm sie ihr den weiß überschneiten Pelz von den Schultern und schüttelte ihn aus, wobei sie aber sorglich jedes Geräusch vermied.

»Dadrinnen steckt Taraß tief bis über die Ohren in einer Arbeit über das Vogelgetier,« flüsterte sie in ihrem weichen Russisch, das an sich schon zärtlich klang, und wies auf das Hauptzimmer der kleinen Wohnung.

Erst jetzt bemerkte Marianne die breite buntgestreifte Küchenschürze an ihr, und daß sie die Aermel hochgezogen hatte. Eine Messerbank, nach der sie griff, mußte sie eben erst hastig aus der Hand gestellt haben.

Im Hintergrunde des engen dämmerigen Vorflurs stand die Thür zur Küche noch offen; man sah die Holzscheite im Herdfeuer rot glimmen.

»Ja, unser Mädchen ist nämlich schon wieder krank. Sie ist wirklich ewig krank, diese Aermste,« sagte die junge Frau und zog Marianne in die Wohnstube.

Die Wohnstube war ziemlich groß, niedrig und so dicht über dem Hof, daß der gegenüberliegende Schneehaufen sie schon verfinstern konnte. Auf dem Hof flogen weiße und graue wohlgemästete Tauben umher, flatterten auf den Fenstersims und schlugen mit ihren Flügeln an die Scheiben, an denen drinnen blühende Azaleen standen.

Ein Teil des Zimmers wurde durch zwei mitten hineingebaute mannshohe Scheinwände isoliert, hier befand sich der Schlafraum. Die zurückgeschobene Portière ließ das Ehebett unter einem Baldachin von geblümtem Stoff sehen, sowie die Ecke mit den Heiligenbildern. Ein paar davon besaßen schwere Silberverkleidung; unter ihnen hingen gestickte Handtücher und lagen auf einem Wandbort geweihte Brötchen.

Im Wohnraum am Fenster stand breit und bequem ein Tisch, worauf sich in friedlichem Nebeneinander Schreibereien und Hausarbeiten, nicht grade zierlich geordnet, befanden. Auf einem Seitentisch zeigte der nie fehlende blitzende Samowar, daß hier auch gespeist wurde.

Marianne hatte es sich wunderschön behaglich gemacht in einem Großvaterstuhl, der dicht bei einem wärmeausstrahlenden Kachelofen von anerkennenswerten Dimensionen stand. Neben dem Ofen hing am Bande eine altertümliche kleinrussische Guitarre, eine Gusli. Fröstelnd vergrub Marianne ihre durchkälteten Füße im Bärenfell, das sich vor dem Stuhl ausbreitete.

»Das ist unser Diwan, dort sitzen wir immer beide drin,« sagte die junge Frau.

»Ist es jetzt nicht sehr schlimm für euch mit dem kranken Mädchen, Tamara?« fragte Marianne bedauernd. »Da werdet ihr kündigen müssen. Wie treibt ihr es nur überhaupt --? Du alle Morgen in deinem statistischen Bureau, dein Mann über seiner ornithologischen Gelehrsamkeit? Was fangt ihr denn jetzt an?«

Tamara lachte leise auf, ihr ganzes freundliches Gesicht lachte mit.

»Wir treibens, wie es eben geht; -- es wird ja auch wieder besser. Alles wechselt unter dem Mond. Kündigen wollen wir nicht; darauf vertraut die Arme so fest.«

»Russische Sorglosigkeit!« dachte Marianne bei sich. Aber sie mochte nichts Tadelndes äußern, sie wiegte sich darin wie in etwas Wohlthuendem.

Vielleicht wäre es anderswo tadelnswerter gewesen, doch ihr schien immer: wo man unter russischen Menschen war, wo diese Sprache klang, da wurde das Leben in der That in allen Dingen gleichsam simpler und weiter, -- vertrauender. Obschon sie selber kein russischer Mensch war, so zählte sie doch nicht zufällig unter diesen ihre besten Freunde.

»Aber überanstrengt es dich auch nicht, Tamara?« meinte sie besorgt. »Noch kann es ja eine ganze Weile dauern, ehe dein Mann die verdiente Berufung bekommt, und ehe du also dem statistischen Bureau ein Schnippchen schlagen kannst.«

Tamara schüttelte belustigt den Kopf, von dem zwei starke Zöpfe unaufgesteckt niederhingen.

»Bis dahin hilft mir eben mein Mann. Wenn ich nicht mal _das_ von Ihnen gelernt hätte, Marianne Martinowna: gute Laune am Alltag bewahren, -- die schönste Lektion, die Sie unbewußt allen Ihren Schülern mitgeben, -- gratis neben all dem Schulkram.« Tamara fuhr ungeniert mit dem Messerputzen fort, worin sie der Besuch unterbrochen hatte. »Und im Sommer,« bemerkte sie mit aufleuchtendem Blick, »da erholen wir uns schon! Da schlepp ich den Taraß zu den Eltern aufs Gut, oben hinauf nach Wologda, in meine lieben großen Wälder. Da erholen wir uns schon! Ach, warum sind wir da nicht zwei Einsiedler! Sie können mir glauben: ich bin doch gewiß glücklich, aber Heimweh nach den Wäldern und dem Norden hab ich doch. -- -- Aber nun erzählen Sie doch mal von sich? Also die Cita ist heimgekommen?«

Marianne nickte.

»Mit Beginn der deutschen Weihnachtsferien und bleibt bis über die russischen da. Aber ich habe noch so wenig von ihr, -- es war eine so gehetzte Arbeitszeit. Drum wird Weihnachten diesmal so strahlend schön! Mir kommt vor, als ob ich mich seit meiner Kindheit nicht mehr so darauf gefreut hätte, wie dieses Mal. -- -- Immer möcht ich die Cita jetzt nahe um mich haben, -- so ganz nah bei mir, -- -- sie so recht tief anschauen: »»Bist du noch dieselbe? Ist auch nichts an dir verändert? Hat mir die Trennung nichts gestohlen? Zeig mir all dein Schönes: -- das und das und das, -- weißt du noch?«« Ach, Tamara, du hast noch kein Kind, -- kannst du das wohl begreifen?«

Tamara nickte schweigend.

In der Küche hörte man es bedrohlich brodeln und zischen. Sie setzte die Messerbank nieder, lief hinaus, klapperte ein Weilchen draußen zwischen den Tiegeln und Töpfen und kehrte dann in die Stube zurück.

»Ja,« sagte sie, »nun ist also Cita auf dem Wege, etwas Erkleckliches zu werden. Aber, Hand aufs Herz, liebe Marianne Martinowna: wären Sie nicht doch seelenfroh, wenn -- ja wenn sich die Cita ordentlich verliebte und heiratete?«

Marianne blieb einen Augenblick lang stumm. Dann sagte sie fast andächtig: »Wenn über meine Kinder _mein_ Glück käme, -- ein so unfaßbares Frauenglück, das reicher und weiser macht, als alle Reichtümer und Weisheiten der ganzen Welt zusammengenommen, -- wenn ihnen das geschenkt würde! -- -- Und wären es auch nur acht kurze Jahre, wie bei mir, gleichviel. Und käme auch selbst dahinter -- wie bei mir --«

Sie konnte nicht weitersprechen.

Tamara sammelte schweigend ihre Messer zusammen. Nach einer Pause bemerkte sie dabei: »Kenne ja auch die Freude am Lernen. Aber mein heimlichster Traum war doch immer nur der aus dem Märchen von Puschkin, dem Zar Saltan: möchte Gott mir geben, einen Helden, einen Bogatyr, zu gebären! Ja ja, dafür kann man nichts thun. Sonst wär es ja auch nur wieder armseliges Menschenwerk. So ist es: Studium ist Verdienst, aber Liebe ist Gnade. -- Aber ganz jammerschade scheint es mir, daß Sie nicht mit Ihren beiden Kindern zusammenleben können wegen des Studiums, -- gradezu eine Missethat scheint es mir manchmal.«

Marianne fiel rasch ein: »Darüber muß man nicht nachdenken. Es ist nicht anders. Ich muß Sophie doppelt geben, doppelt --«

»Aber ich hätte Ihnen einen kuriosen Vorschlag zu machen,« meinte Tamara, »wenn nur Cita nicht grade in Berlin studierte.«

»Einen Vorschlag --?«

»Ja, von meiner Tante bin ich dazu autorisiert, -- wissen Sie, von der, die in Bern das Mädchenpensionat leitet und voriges Jahr hier war.«

»Ach, thut sie das noch immer? Sie klagte doch schon so über ihr Alter und ihre Gebrechlichkeit. -- -- Will sie es etwa abtreten?« fragte Marianne mit unverhohlener Spannung.

»Sie möchte gern einer Hilfe die Leitung übergeben. Sie wissen: es sind lauter unerwachsne Mädchen, vielfach Russinnen, die dort den sogenannten letzten Schliff bekommen. -- -- Und auf Sie hält sie so große Stücke, sie wäre entzückt. Aber es wäre doch wohl nichts?«

Marianne schüttelte zögernd den Kopf. Im stillen rechnete sie nach. Es war ihr klar, daß sie hier mehr verdienen konnte. Und schließlich blieb Cita auch dann weit von ihr.

Aber wenn es doch möglich wäre, -- mit Cita? Sie wurde ganz still und hörte nicht auf, zu rechnen.

An der Thür, die das Wohnzimmer mit der größern Hauptstube verband, wurden rasche, ungeregelte Schläge hörbar, wie ein Geprassel von Kleingewehrfeuer.

Tamara sagte mit befriedigtem Lachen: »Das ist Taraß' Triumphgeschrei: er hat für heute glücklich sein Ei gelegt. Es ist auch hohe Zeit, daß er frei wird. Ich muß schnell den Tisch decken.«

»Und ich muß leider weiter wandern,« äußerte Marianne mit einem Seufzer; sie erhob sich ungern aus ihrer weichen, behaglichen Ecke.

Tamara nickte betrübt.

»Wir armen Arbeitsgäule,« meinte sie lächelnd und stieß die Thür nach dem Vorflur auf, laut rufend: »Taraß, bist du da? Komm doch mal her, Marianne Martinowna muß schon fortgehn.«

»Jawohl!« schrie es aus der Küche zurück, »aber dann mußt du herkommen, -- das Zeug brennt an!«

Der Ton der Verzweiflung, worin das verkündet wurde, erheiterte Marianne. Sie trat auf den Vorflur hinaus und schaute nach der Küche. Tamara war, die Hände ringend, schon an ihr vorbei vorausgeschlüpft.

Zwischen seinem Studierzimmer, das weit offen war, und der Küche mitten drin stand auf dem Vorflur Tamaras Mann mit lebhaft vorgerecktem Hals und richtete seine Augen angsterfüllt auf eine Pfanne, die auf dem Herde stand und furchtbar zischte. Die Brille hatte er sich auf die Stirn geschoben.

Seine Frau stürzte zur Pfanne.

»Geh nicht so nah heran, geh ihr nicht nah!« rief er beängstigt, »-- das Zeug spritzt! Man darf sie nur von hier aus ansehen. Es spritzt! Paß auf, es spritzt in die Augen!«

Als das Zischen und Prasseln gelinder wurde, wandte er sich aufatmend der lachenden Marianne zu. Auch er lachte nun. Aus seinem hübschen dunkeln Bart, der tief über das gestickte russische Hemd fiel, das er zu Hause trug, schimmerten die Zähne.

»Ja, ich war nun grade fertig, -- und angerührt hatte sie die Geschichte ja, ich sollte nur Wache halten, -- aber aufregend ist die Sache ungeheuer, -- uff!« und er fuhr sich über die Stirn und die etwas wildgewordenen krausen Haarringel.

Tamara, die am Herde herumwirtschaftete, rief: »Ja, darin ist er gut, wirklich! Sie sollten nur wissen, was wir uns beide alles zusammenkochen. Aber ohne Herzklopfen geht es eigentlich nie ab. -- -- Die reine Nervenkur. -- -- Er thut es auch nur, um wenigstens gelegentlich zu beweisen, daß ich ihm neben seinen Vögeln doch auch was gelte.«

Sie kam aus der Küche, streifte die Aermel herunter und trat zu Marianne, die sich grade an den Vögeln ergötzte, die man im offenstehenden Arbeitszimmer sah. Jeder Platz, den die Bücher übrig gelassen hatten, gehörte den Vögeln, -- toten, ausgestopften Bälgen -- und lebendigen in zwei Riesenkäfigen, aus denen es zwitscherte, piepte und sang.

»Ja, denken Sie nur,« behauptete Tamara, »sein Getier konnte er sogar auf der Hochzeitsreise nicht vergessen. Ich konnte nicht gefühlvoll gegen ihn werden, ohne daß er mir sofort auseinandersetzte, wie es zum Beispiel die Enten und Gänse in ihren Liebesspielen untereinander halten. Damals schrieb er nämlich grade über die. Zuletzt war ich ganz beschämt, keine Gans zu sein.«

Ihr Mann wurde verlegen, aus seinen träumerischen dunkeln Augen sah er Marianne hilflos an.

»So war es gar nicht, -- nein, so war es nicht,« bestritt er lebhaft. »Ich habe nur gesagt: ein Gelehrter zu sein, das ist nichts ohne Liebe. Man muß die Tiere lieben, dann versteht man sie gut. Und dann habe ich ihr erzählt, die Enten wären --«

Aber seine Frau fiel ihm ins Wort. Vom nächststehenden Tisch in seinem Zimmer hatte sie geschwind ein dickes Buch aufgegriffen, ein Werk von ihm, schlug es fachkundig auf und las mit heller Stimme:

»Beispielsweise -- =pagina= 136: ›Alle Männchen ziehen sich nahe zusammen. Dann schwimmt je ein Weibchen zwischen ihren Reihen schnell hindurch. Hierauf schnellen die Männchen im Takt in die Höhe, biegen dann den Schnabel gegen die Bauchmitte und pfeifen =a tempo=. Verpaßt einer der Enteriche dabei den genauen Anschluß, so scheint das etwas Uebles zu sein: er muß alsdann seine Kräuselfedern in die Höhe richten und vernehmlich: ›Räp!‹ rufen --‹«

»Schäme dich! schäme dich!« rief Taraß laut, »ich habe dir nicht so was vorgelesen, -- ich habe dir Lieder zur Gusli gesungen!«

»Ja, wissen Sie warum?« Tamara legte das Buch aus der Hand, »um mir mit kleinrussischen Klängen mein Nordrußland zu verleiden! Ist denn Kleinrußland noch Rußland?! Ach, wir zanken uns darüber noch bis zu Tode!«

»Nicht wahr! nicht wahr!« rief Taraß dazwischen, »die schönsten Lieder und die schönsten Sagen sind im Norden und Süden gleich! Der blinde Sänger unten bei uns singt dir, was bei euch gesungen wird. Aber vom Süden hinauf ist es gekommen!«

»Vom Norden zu Euch ist es gekommen!« ereiferte sich Tamara, »von da oben, wo alles rein russisch blieb. Wo auch später nicht einmal der Tatar hindrang --.«

Marianne verließ sie zwischen Küche und Stubenthür im vollsten Streit. Sie lachte noch, als sie auf den Hof hinaustrat zwischen die gurrenden Tauben. Beschämt sah sie nach ihrer Uhr. Noch konnte sie rechtzeitig zur Unterrichtsstunde kommen, doch mußte sie sich tüchtig beeilen.

Eine Weile später durfte sie endlich für kurze Zeit heimgehn. --

Obgleich Marianne müde war, machte sie den Heimweg zu Fuß. Das Schneetreiben hatte nachgelassen, hier und da schaute schon die Wintersonne freundlich zwischen zerrissnem Gewölk hervor.

Marianne liebte es, durch diese Straßen zu wandern, die ihr bei ihren Gängen tagein, tagaus, jahrein, jahraus vertraut geworden waren wie ein Heimatort. Das Ungeordnete und Halbasiatische auf vielen von ihnen störte sie nicht mehr, -- nicht die Bettler oder Betrunkenen, die ihr begegneten, nicht die grellbemalten Schenkenschilder mitten zwischen dem bizarren Glanz der zahllosen Kirchen und Kapellchen.

Und sie mußte lächeln, wenn sie schmale, hügelige Gassen sich plötzlich auf einen jener Riesenplätze öffnen sah, die wie weite Ebenen sein konnten, und an deren Rande mitunter kleine Häuser kindlich dastanden wie Spielzeug neben den ungeheuren Raumverhältnissen mancher Nachbarbauten.

Denn der Raum hatte hier keine Bedeutung, keinen Hochmut; keine Pracht schien sich ihrer Größe zu rühmen, und keine Bescheidenheit möglichst eng zusammenzukriechen. Größe und Kleinheit warfen friedlich ihren Wert in eins, nachlässig zu einander gesellt, wie Baum und Grashalm in derselben Landschaft.

Sogar der Kreml, der von jedem Punkt Allgegenwärtige, erschien fast nur zufällig groß: als im Grunde wesensgleich irgend einem der kleinen heiligen Altarschreine in Kapellenform, wie sie Fürst und Bauer zu eigen besitzen, -- aber von der Inbrunst einer gewaltigen Andacht irgend wann einmal in solchen Dimensionen geschaut und fixiert, daß er fortan immer allen sichtbar blieb, immer allen gemeinsam gehörte --.

Mitten in der Stadt sah sie, wie dort so oft, ein kleines mageres Füllen neben dem Mutterpferd traben, das einen Lastwagen zog. Das glückliche Pferd! es brauchte nicht von seinem Kinde fort, wenn es auf Arbeit ging.

Marianne fand: alle Arbeit, die Frauen thun, müßte so weise eingerichtet sein.

Sie seufzte und ging rascher.

Beim Ueberschreiten eines Fahrdammes mußte Marianne innehalten, weil zwei Gefährte ineinander geraten waren, was beim wahllosen Durcheinanderjagen leicht genug geschah.

Die Fuhrleute schrieen sich an und fluchten sich gegenseitig in die Hölle; der eine Schlitten wurde frei und flog weiter, am andern war der Gaul ausgeglitten und gestürzt.

Ein Mann, der den Schnee vom Fußsteig schaufelte, trat heran, um zu helfen, doch keine Neugierigen blieben gaffend stehn. Nur ein kleines Mädchen mit rotem Kopftuch schaute auf das daliegende Pferd und kraute es im Vorübergehn mitleidig, mit ganz schüchterner Liebkosung, am Stirnhaar, wie um es zu trösten. Ein Schlitten kam an der Gruppe vorbei und hielt jählings an.

Tomasow saß darin. Er warf dem Kutscher ein Geldstück zu, sprang heraus und ging auf Marianne zu.

»=Quelle chance, madame!=« sagte er lächelnd, und streckte die Hand aus.

»Und nun begleiten Sie mich nach Hause!« meinte sie gleich.

»Aber selbstverständlich.«

»Das heißt, -- falls Sie nicht etwas Wichtigeres vorhaben --?«

Tomasow machte ein etwas spöttisches Gesicht.

»Was sollte ein Tagedieb wie ich besonders Wichtiges vorhaben?«

»Tagedieb! O pfui!« Sie war entrüstet; -- »Sie sind ja doch Arzt!«

»Nicht allzusehr. Mir würde es vielleicht bald genügen, Ihrer Gnaden, Frau Mas, Leibarzt zu sein.«

Aber sie ging auf den scherzenden Ton nicht ein.

»Dafür sind Sie noch zu jung, um sich zurückzuziehen. Das wäre sehr, sehr schade. Für viele!« antwortete sie ernst.

»Aber ganz und gar nicht! Hier gibt es genug Aerzte für Moskau, -- viel zu viele, -- sie treten einander auf die Füße. Es ist gradezu eine gute That, Raum für sie zu schaffen. -- Sie werden sagen: in der Provinz? Ja, das ist schon etwas andres. Aber Sie wissen, dafür bin ich verdorben. Es fehlt mir durchaus an der nötigen Aufopferungslust, um in irgend einem Winkel zu versimpeln, -- als Menschheitsheros oder als stiller Säufer.«

»Sie sind heute entsetzlich garstig!« rief Marianne und hielt ihren Muff ans Ohr. Sie lief förmlich von ihm fort. »Warum machen Sie sich schlecht vor mir? Warum nur? Ich weiß schon selbst, ob Sie was taugen oder nicht.«

Tomasow suchte nach seinem Kneifer, den er selten trug, und setzte ihn auf, was seinen Gesichtsausdruck ganz verwandelte, als setze er eine Maske auf.

»Laufen Sie nicht so schrecklich geschwind,« sagte er; »wollen wir nicht überhaupt fahren?«

Marianne schüttelte abwehrend den Kopf.

»Nein, ich muß ohnehin so viel sitzen. Und die Luft thut jetzt gut. Ich gehe so gern durch all die Buntheit und Herzlichkeit des Straßenlebens hier; wenns die Zeit nur öfter erlaubte! Sie nicht?«

Tomasow zuckte mit einer Gewohnheitsgebärde die Achseln.

»Wie mans nimmt. Meistens ärgere ich mich dabei, weil ich mich frage, warum in aller Welt einen das Heimweh immer wieder auf den alten Fleck zurückzieht? So oft ich versuche, auf längere Zeit fortzugehn, -- ich komme doch wieder. Was soll man aber hier? Ja, wäre man noch ein richtiger dem Grabe entstiegener Altrusse von vor Peters Zeiten, so einer mit langem Bart und langem Kaftan --! Denn sonst würgt man hier ja nur an alledem, wozu man sich eventuell im europäischen Geistestreiben mit entwickelt hat. -- -- Ich will mich nicht entschuldigen, aber das macht so merkwürdig indolent.«

»Sobald Sie Ihre Russen von Herzen lieben, haben Sie auch einen Wirkungskreis unter ihnen,« meinte Marianne.

»O nein! Das ist ein Irrtum. Sehen Sie sich nur einmal das Volk an mit seinem breiten Gleichmut gegen die ganze eigentliche Welt der Kultur, -- wie es alle seine wirklich tiefen Interessen anderswo hat, -- was weiß ich, wo: bei Wind, Wetter, Tod, Musik, Ammenmärchen, Heiligenbildern -- --. Mit seinen Aufklärern war es noch nie eins. Gegen sie lehnt es sich auf. Und dies Naturell, dies seelische Tempo, ist mindestens ebenso oft schuld an seinem Zurückbleiben, wie unsere oft verrufenen Zustände.«

»Ich weiß schon! Fangen Sie nur nicht an zu politisieren!« sagte Marianne. -- »Lieber will ich es sein, die Ihnen von diesem Volk erzählt: zum Beispiel könnte ich Ihnen davon erzählen, warum ich hier, in dieser russischen Stadt, so gern grade an Sonntagen eine Gemäldegalerie besuche, wo auch das Volk vor den Bildern steht --. Es tritt leise auf mit seinen schweren Stiefeln und ist voll von Andacht. Haben Sie eine solche Andacht schon anderswo häufig beobachtet? Man muß nur in des Volkes seelische Art eingehn, um seine Seele zu fassen.«

»Das mag alles sein. Indessen für den einzelnen bleibt das geistige Unbehagen, hier zu leben, weil das Volk in seiner Aufklärung noch nicht weiter ist.«

»-- Oder weil wir nicht tiefer sind, mit all unserm Geist,« meinte Marianne nachdenklich. »Jedes Menschenleben sollte doch von jedem Punkt aus, durch die aufrichtige Macht seines Erlebens, bis in alle Tiefen gelangen können, -- nicht nur da, wo der Verstand es so herrlich weit gebracht hat. Könnten wir uns nicht durch unsre einseitige Geistigkeit um dieses Kostbarste bringen? -- -- Was Ihnen hier auf die Nerven fällt, mein lieber Freund, das thut mir so unendlich wohl bis in alle Nerven. Es ist wie ein Trost, wenigstens für den, der, wie ich, nicht mehr mit kann in der großen Kulturhetze, in den immer rastlosern Fortschritten, in der ganzen nimmersatten Selbstentwicklung --«

Marianne sprach lebhaft, fast übereifrig.

Tomasow warf ihr einen aufmerksamen Blick zu. Es war selten, daß sie etwas äußerte, was wie Resignation über ihren Tagesberuf klang, der sie zu nichts anderm kommen ließ.

»Ein Trost, den Sie aber doch am allerwenigsten brauchen,« bemerkte er, »so frisch und angeregt wie Sie --«

»-- Von Stunde zu Stunde laufen!« ergänzte sie mit gutmütiger Ironie. »Ja, so ist es nun einmal: Zeit und Schwung läßt das nicht übrig. Und ich würde jetzt eine traurige Rolle spielen in euren glänzenden Geisteszirkeln, unter euren entwickelten Menschen, von denen Cita und auch Sie so gern aus eurem ausländischen Leben erzählen --«

»Unsinn, Ma!« fiel er ein. »Niemand in der Welt eignet sich so herrlich dazu, wie Sie, zwischen solchen Menschen zu leben. Sie würden dort strahlen --«

Marianne schüttelte den Kopf.

»Nein, das würd ich wohl nicht, und das will ich ja auch gar nicht. Aber es ist doch gut für mich, daß ich nicht so ganz nah dabei stehn muß --. Ich würde die Liebe zu meinem Alltagsdasein nicht festzuhalten vermögen und fühle doch: sie ist das allein Wichtige, das allein Ausschlaggebende -- --. Hier gibt es ja genug Hochstehende, Schaffende, Menschen über den Alltag hinaus. Aber sie leben einsam, und leben insgeheim doch nur für das Volk. Schon der Lärm der offiziellen Hauptstadt ist ihnen zu viel, deshalb ziehen sie hierher, -- und am liebsten weit hinaus, bis an die Grenzen der Stadt, wo schon die Gärten beginnen.«

Marianne nahm Tomasows Arm und fuhr leiser fort: »Ihnen will ich gestehn, daß ich manchmal, aus tiefer Sehnsucht nach Erquickung heraus, hier und da ein Künstleratelier besucht habe -- --. Aber auch die, zu denen ich nie gekommen bin, meine ich zu kennen, als hätte ich heimliche Zugänge zu ihnen in allen müden Stunden. -- Für mich gibt es noch ein zweites Moskau in Moskau, -- mit stillern Straßen, als die ich Tag für Tag betrete, und mit Häusern, wo große Menschen wohnen, die ich verehre. Und manchmal, wenn ich so von Stunde zu Stunde haste, belebe ich meine eigne Ermüdung damit, daß ich mir einbilde, ich ginge gar nicht zu meiner Lehrstunde, sondern zu einem von ihnen --.«

»Und immer noch wieder leben Sie ein Leben, wovon man nichts weiß!« entfuhr es Tomasow. -- »Wie können Sie nur von Schwunglosigkeit sprechen? Wer so viel Trost wie Sie schöpft aus --«

»Warten Sie einen Augenblick!« unterbrach Marianne ihn unvermittelt und zwang ihn, mitten auf der Straße stillzustehn, während sie sehnsüchtig nach den ausgelegten Waren eines Straßenobsthändlers hinsah.

Der junge Bursche hatte sein Fruchtbrett vom Kopf gehoben und hielt, sich vor Marianne und Tomasow auf ein Knie niederlassend, ihnen erwartungsvoll seine Zitronen, Aepfel und prachtvollen Südtrauben entgegen.

»Ach, wer kann an so etwas vorübergehn!« bemerkte Marianne seufzend und wählte mit entzückten Augen unter den großen tiefblauen Trauben. Tomasow sah zu, wie eifrig sie bei der Sache waren, der junge Händler und sie. Beide lachten vor Vergnügen.

»Eben wollte ich damit anfangen, Sie über allerlei zu trösten; aber ich sehe, es ist gar nicht mehr nötig,« sagte er, als Marianne fertig war; »Sie sehen aus wie ein beschenktes Kind.«

»Diese sind auch extra schön! Ich freu mich auf das Erstaunen der Kinder,« entgegnete sie, schneller ausschreitend, und steckte die Düte hinter ihren Muff; »beide essen sie gern. -- Aber wir sind wirklich gleich zu Hause! Wollen Sie nicht ein wenig mit hinaufkommen? Die Kinder würden so froh sein --«

»O nein, die haben ja schon die Trauben!« sagte er spitz und schüttelte den Kopf. »Aber ich würde für mein Leben gern einmal so ein Obstbrett vor Ihnen ausbreiten, Marianne, -- die schönsten Früchte, -- ganz unwahrscheinlich schöne, -- damit Sie dann so aussehen, wie jetzt eben.«

»Dummes Zeug!« meinte sie ärgerlich, »übrigens habe ich ja fast alles Schöne, was ich besitze, von Ihnen mal geschenkt bekommen. Ist Ihnen das nicht genug?«

»Geschenkt? Von mir? Ich wüßte nicht. Es ist nur Ihre eigenste Spezialität, die Dinge so aufzufassen, als kämen sie Ihnen von andern. Wenn ich Ihnen wirklich schenken wollte, wär es ganz anders --«

Marianne blieb stehn. Sie waren am Hause angelangt.

»Danke für Ihre Begleitung!« sagte sie und gab ihm die Hand. »Sie sind zwar mitunter garstig gewesen, aber im ganzen doch gut, wie immer.«

Er antwortete langsam: »Ein klein wenig garstig waren auch Sie. -- -- Daß Sie mich Ihren Kindern mitbringen wollten, -- gleichsam eine zweite Düte, neben den Trauben. -- -- Nun, irgendwann werden Sie das schon noch einsehen.«

»Auf Wiedersehen!« rief sie heiter und öffnete die Hausthür.

»Auf Wiedersehen, Ma! So bald als möglich auf Wiedersehen!«

Marianne lief rasch wie ein Mädchen die zwei Treppen hinauf, oben mußte sie Atem schöpfen, als sie den Schlüssel in die Thür steckte. Aber alle ihre Ermüdung war verflogen, das Sprechen und Scherzen mit dem Freunde hatten sie von ihr fortgenommen.

Oben schien Besuch zu sein.

Sie trat vom Vorflur in ihr Wohnzimmer. Ja, da saß ein junger, ganz junger blonder Mann mit ihren beiden Töchtern und erhob sich ehrfurchtsvoll, als er ihrer ansichtig wurde.

»Dies ist Herr Hugo Lanz, Ma,« sagte Sophie vorstellend, »-- du weißt, wir trafen uns neulich in der Gesellschaft --«

»Ich komme nur als Abgesandter meiner Verwandten, gnädige Frau,« erklärte Hugo Lanz mit einer weichen sympathischen Stimme, »es handelt sich um eine Schlittenfahrt für heute abend. Vor zehn Uhr sind alle wieder heimgeleitet.«

»Das ist freundlich von Ihnen,« entgegnete Ma und reichte ihm die Hand, »ja, fahrt nur, ihr Kinder.«

»Und du, Ma?« fragte Cita.

»Ich bin ja heute abend zum Thee bei Tante Ottilie und werde euch dort entschuldigen, ihr Nichtsnutze.«

»Aber du wirst heute zu müde sein, Ma,« meinte Sophie bedenklich und küßte die Mutter.

»Nein, Kind, ich bin jetzt so frisch. Und morgen ist Sonntag. -- -- Aber wer fliegt jetzt wie ein Pfeil und zaubert mir geschwind eine heiße, starke Tasse Thee oder Kakao herbei?«

Die Mädchen stürzten zur Thür.

Hugo Lanz sah so heftig diensteifrig aus, als wollte auch er stürzen, aber er besann sich rechtzeitig auf das Zwecklose eines solchen Unternehmens.

»Thee also!« rief Sophie.

»Nein, besser Kakao!« rief Cita.

Sie verschwanden, und Hugo Lanz blickte ihnen ernsthaft nach -- mit einem Gesicht, als hätte eine jede von ihnen etwas Geistreiches ausgesprochen, was lange dunkel in ihm gelegen habe.

Marianne sah den Blick und sah ihn selbst an und war ihm gut. Daß ihm die Gesellschaft dieser jungen, hübschen und geweckten Mädchen ausnehmend gefiel, begriff sie vollkommen und fand es in der Ordnung. Auch fürchtete sie nie, daß ihre Töchter je zu »gelehrt« werden könnten, um zu gefallen. Ihr war zu gut bekannt, wie sehr dabei nicht der Kopf, sondern das Temperament entscheidet.

»Sie sind noch nicht lange hier?« bemerkte sie freundlich, um dem Gast die Zwischenzeit füllen zu helfen.

»Nein. Ueberhaupt nur für einige Monate zu Besuch bei hiesigen Verwandten. Dann soll ich nach Deutschland zurück, um Kaufmann zu werden.«

Er sagte das trübe. Sie fragte nicht, doch traf ihn ihr Blick so warm und mütterlich, daß er spontan fortfuhr: »Mein Traum war, Künstler zu werden.«

Sie fragte auch nicht: in welcher Kunst? Sie sagte nur sehr weich:

»Der höchste Traum. Und die schwerste Erfüllung.«

Er hob die Augen bescheiden zu ihr.

»Aber man soll doch nicht gleich anfangs verzagen, nicht wahr? Ich fühle so bestimmt: ich könnte mich dazu durchringen, wenn man mich nicht so ganz in die Familie einengen wollte. Ein Künstler und jeder, der es werden will, braucht Freiheit.«

Marianne nickte.

»Mehr als Freiheit: Heimat,« sagte sie unwillkürlich.

Hugo Lanz sah sie fragend und wie erwartend an. Ihre Art und Weise nahm ihn leise gefangen.

»Ich meine,« versuchte Marianne zu erklären, »niemand braucht so sehr als er breitesten Spielraum, weil alle seine Bewegungen unberechenbarer, unbezwingbarer sind, als die irgend welcher andern Entwicklung. Aber in seiner angebornen Sensitivität, in seiner fast hilflosen Eindrucksfähigkeit hat er zugleich, wie niemand anders, Furcht vor der Fremde. Seine Freiheit mag sich noch so breit strecken wollen, aber an den äußersten Grenzen seiner Freiheit, da muß er Heimat um sich fühlen, -- eine Welt, der er vertraut.«

Aus dem Klang ihrer Stimme vibrierte etwas, als wenn sie jedes ihrer Worte aus tiefen, warmen Glückserfahrungen hebe. Weniger in den Worten selbst, als in diesem Stimmklang lag etwas Suggestives, was Hugo Lanz ergriff.

»Das ist so nur in einem Paradies!« rief er. -- »In Wirklichkeit gibt es das nicht,« setzte er traurig hinzu.

Marianne widersprach nicht.

Sie schwieg, doch ihre Augen widersprachen. Sie leuchteten in so ruhigem Glanz und wendeten sich unwillkürlich dem verschlossnen Rahmen auf dem Schreibtisch zu.

Da vernahm man von der Thür her Gelächter.

Die Mädchen kehrten zurück, jede mit einer vollgefüllten Tasse in der Hand. Den Blick starr auf ihre Tassen geheftet, deren Inhalt überzuschlagen drohte, näherten sie sich langsam und feierlich dem Schreibtisch, neben dem die Mutter auf ihrem gewohnten Lieblingsstuhle saß.

»Thee schmeckt bei weitem schöner und regt an, hat Ma stets gesagt,« behauptete Sophie.

»Kakao ist ihr bei weitem gesunder, hat Doktor Tomasow stets gesagt,« behauptete Cita, »-- und zwischen dem Schönen und dem Guten, Nützlichen, wirst du doch nicht lange zaudern, Ma! Bedenke auch, welche schlechte Einwirkung ein böses Beispiel auf uns haben, könnte.«

»O du überredest, das ist gegen alle Abmachung!« rief Sophie voll Unwillen.

»Ein Jurist überredet nie genügend, Sophie! -- Also: erst jedenfalls das Schöne, -- und dann auch noch das Gute, Nützliche,« entschied die Mutter sofort und zog lachend alle beiden Tassen zu sich heran.

Cita hockte sich auf die Seitenlehne ihres Lutherstuhles.

»Du unmoralische Mutter!« sagte sie.

Hugo Lanz hatte sich beim Eintritt der Mädchen erhoben. Er sah ganz zerstreut aus. Ihm erschienen mit einemmal alle beide doch noch recht kindisch, ohne daß er ahnte, wie außerordentlich damit sein Urteil in der Richtung fehlging.

Wohl empfand er den heitern Reiz der kleinen harmlosen Familienscene, aber ihm schien, daß alles Intime dieses Reizes doch ganz und gar nur von dieser köstlichen Frau mit der jungen Stimme und den mütterlichen Augen ausginge.

»Wollen Sie wirklich schon gehn?« fragte Marianne freundlich, als er sich jetzt ehrerbietig von ihr verabschiedete. »Nun, ich danke Ihnen noch für die überbrachte Einladung. Und seien Sie uns hier zwanglos willkommen, falls einmal Weg und Stimmung Sie bei uns vorüberführen.«

»-- Ja, gnädige Frau, wenn ich das dürfte, -- dann danke ich Ihnen von ganzem Herzen dafür, aber --« er stockte, »-- dann lassen Sie mich nicht als einen Fremden kommen und gehn, denn das -- das würde ich nach diesem kurzen Gespräch schon nicht mehr ertragen,« fügte er leiser, sehr rasch und, im sichtlichen Kampf gegen seine eigne Schüchternheit, fast heftig hinzu.

Die Bitte, wiederkommen zu dürfen, hatte er vor einer Stunde erst der Töchter wegen an sie richten wollen --.

Marianne gab keinen Bescheid in Worten, aber er empfand ihr ganzes Wesen als eine Antwort. Mit Bestimmtheit fühlte er, daß er von heute an hier nur noch einkehren würde, wie man bei einer Mutter einkehrt, und nur allein ihretwegen.

Als er sich beim Abschied über ihre Hand beugte, gab ihm Marianne unwillkürlich jenen Stirnkuß, auf den nach russischer Haussitte der Gast Anspruch hat. Und als er sein Gesicht erhob, lag eine so dankbare Kindlichkeit auf seinen jungen Zügen, daß sie Marianne rührte.

Sobald sich die Zimmerthür hinter ihm geschlossen hatte, bemerkte Cita mit einem Lächeln: »_Der_ sah dich ja aber mal eben kurios an, Ma. Weißt du, wie? Ungefähr so, wie wenns ihm schlecht ginge, und er dir gleich den Kopf in den Schoß wühlen möchte, um dir zu beichten und von dir getröstet zu werden.«

Sophie mußte lachen.

Cita fuhr, nicht ganz frei von Spott, fort: »Ja, sind Männer nicht eigentlich höchst wunderliche Pflanzen? So etwas Unmännliches sind sie, scheint mir. Es klingt gewiß dumm, aber sag selbst, Ma! Könntest du dir leicht vorstellen, daß ich irgend jemand so -- so hilfsbedürftig ansähe? Nein, im Gegenteil: kerzengrade würd ich mich grade dann recken. -- -- Alles andre ist eben Schwäche.«

Marianne lächelte fein.

»Nicht notwendig Schwäche. -- -- Schwere Aehren stehn auch nicht kerzengrade,« sagte sie.

Aber in ihrem Innern empfand sie bei Citas Worten einen heimlichen Stich. Cita, ihr tüchtiges, kernfestes Mädchen! Sie konnte ihr vertrauen und mit ihr reden über alle Sorgen und Nöte, fast wie mit einem klugen Freunde, ja fast wie mit einem Mann --.

Ja, das alles konnte sie. Aber -- den Kopf noch einmal anschmiegungsbedürftig in Mas Schoß wühlen, das würde Cita doch wohl nie mehr --.

Sophie hatte sich ans Fenster gestellt. Sie sah Hugo Lanz, der aus dem Hause herausgetreten war, unten über den Fahrdamm gehn. Er sah schlank und fein aus in der dunkeln Pelzmütze und trotz des Pelzes, der alle Konturen vermischte. Eigentlich gefiel er ihr doch sehr gut, viel besser, als sie es Citas Spottlust einzugestehn wagte.

Jetzt äußerte sie aber doch:

»Du, -- den mag ich trotzdem gern. Warum soll er auch Ma nicht angucken, wie er will? -- -- Ich habe mich mit ihm schon prachtvoll unterhalten, neulich in der Gesellschaft, ehe du hier warst, Cita. Ich erzählte ihm von den höhern Mädchenkursen, und dann, daß mich die Naturwissenschaften so sehr interessieren, -- daß ich aber noch weit lieber ein Arzt würde, -- grade wie Doktor Tomasow.«

»Aber das alles sind ja dem jungen Dichter völlig gleichgültige Beschäftigungen, Sophie,« meinte Cita und trug die Tassen der Mutter hinaus.

»Die Beschäftigungen an sich: ja!« gab Sophie kleinlaut zu und schaute noch immer angestrengt einem dunkeln Punkt in weiter Entfernung -- einer Pelzmütze -- nach, obschon sie nicht mehr ganz sicher war, ob es nicht längst eine andre Mütze auf dem Kopfe eines andern sei. »Aber,« fuhr sie eifrig fort, »auf die Art der Beschäftigung kommt es auch nicht an, sondern darauf, daß er _auch_ hinausstrebt, -- fort, hinaus! Mit dem einzigen Unterschied, daß er das infolge von Gedichten thut. Das schadet aber doch nichts. Die Hauptsache haben wir doch gemeinsam. Auch ihm ist eng, auch er hat allerlei Träume, die er kaum zu Hause zu

nennen wagt, -- auch seine Pläne lassen sich nun einmal nicht zu Hause verwirklichen. Und seine Familie, -- die hält ihn. Wie sollten wir da nicht sympathisieren?! Wie sehr kann ich ihm doch das alles nachfüh--.«

Sie stockte jäh.

Die Nase an die Scheibe gedrückt, hatte sie ganz vergessen, wo sie sich eigentlich befand. Ihr ward plötzlich erst bewußt, was sie da sagte.

Cita konnte es überhaupt nicht mehr hören, die war ja eben mit den beiden Tassen hinausgegangen.

Aber da, im Luthersessel vor dem Schreibtisch, mit dem Gesicht grade zum Fenster, da saß, Sophie im Rücken, ganz schweigsam -- Ma --

Einen Augenblick lang, einen Augenblick nur, war ihr Ma wirklich ganz und gar aus dem Gedächtnis entschwunden gewesen.

Wohl eine volle Minute stand Sophie wie erstarrt. Sie bekam ein Gefühl, als wär es noch besser, sich mit ihrer kleinen Nase ganz durch das Fensterglas durchzubohren, um nie, nie wieder die Augen zurückwenden zu müssen.

Ihr Herz schlug heftig, sprunghaft, die Lippen wurden ihr trocken. »Arme, süße, liebe Ma!« dachte sie außer sich, voller Wut.

Plötzlich drehte sich Sophie gewaltsam um, zu ihrem eignen Schreck. Sie sah das Zimmer vor sich wie im Nebel. Sie lief auf die Mutter zu, fiel vor ihr auf die Kniee und umhalste sie wortlos, stürmisch.

»Ach Ma, -- dummes Zeug -- solch dummes, -- ich benutzte unwillkürlich seine Worte, -- weißt du: einfach seine Worte -- sie passen ja auch einzig und allein für ihn, alle, alle diese Worte!« stammelte sie endlich, ganz in Thränen, und dann lachte sie fast ein wenig, verlegen und sonderbar.

Marianne herzte sie ganz leise.

»Aber -- du wildes Mädchen, -- wie kann man sich dermaßen erregen! Viel zu leicht erregt bist du, weißt du das? Du mußt dich besser zusammennehmen. -- Komm, sei nun wieder ruhig und mein liebes altes heitres Kind, -- ja?«

Sophie hob den Kopf. Bei diesen sanften Worten verflog langsam ihr Schreck, sänftigte sich auch ihre Reue. -- Vielleicht hatte Ma gar nicht so genau hingehört vorhin -- --.

Marianne strich ihr liebreich über das schimmernde blonde Haar. Ihre Augen aber schauten großgeöffnet über ihr Kind hinweg.

Dann stand sie auf.

»Man braucht nur ein wenig wieder ›daheim‹ zu sein, um gleich wieder zu vergessen, daß es auch noch ein ›Draußen‹ mit allerlei Pflichten gibt, -- ich muß ja fort,« sagte sie zu Cita, die eben eintrat und einen heimlich verwunderten Blick auf das thränenfeuchte, gerötete Gesicht der Schwester warf.

»Ach, mußt du schon gehn, Ma? Ist es nicht zu früh?« Cita holte schnell den Pelz und die Ueberschuhe vom Vorflur herein. »Komm, ich helfe dir! Du wirst wohl von Tante Ottilie später nach Hause kommen, als wir.«

»Wohl nur wenig später,« meinte Marianne, »und ihr wißt: wer zuerst kommt, geht schlafen, ohne zu warten, -- nach unsrer alten Verabredung.«

»Es ist aber wirklich noch viel zu früh, deine Stunde fängt viel später an,« murmelte Sophie, die der Schwester Mas Ueberschuhe hastig aus der Hand gezogen hatte. Sie kniete mit ihnen zu Füßen der Mutter, um sie ihr anzuziehen.

Marianne ließ es schweigend geschehen.

»Lebt wohl, ihr Kinder, und vergnügt euch so gut wie möglich! Der Himmel ist jetzt klar, und ich denke, ihr bekommt herrlichen Sternenschein zu eurer Ausfahrt.«

Sie sagte es einfach und harmlos. Aber die Art, wie sie beide noch einmal küßte, war voll unterdrückter Leidenschaftlichkeit. Rasch ging sie fort.

Die reine kalte Winterluft draußen that ihr wohl. Ihr war das Herz plötzlich so schwer geworden, so bange und schwer.

Einen Augenblick lang, vorhin, fühlte sie deutlich, -- so deutlich wie in einer grellen höhnischen Beleuchtung, die sie blendete und verwirrte, -- ihre beiden Kinder fern von sich: die eine lebenssicher, im Grunde fertig, nur noch ein Gast im Mutterheim, und die andre -- ja, die andre sich sehnend, -- sich von ihr hinwegsehnend.

Es war in der That noch nicht die Zeit für die beiden Privatstunden, die sie, ganz in der Nähe von Ottiliens Wohnung, in einem reichen Kaufmannshause zu geben hatte. Es hatte sie nur nicht länger gelitten, mit ihrer wehen Angst, unter den Augen der Kinder.

Marianne ging einige Straßen weit in der Richtung auf ihr Ziel, dann blieb sie unterwegs vor einem Stift für arme Frauen stehn. Von zwei kleinern Nebenbauten flankiert, lag es lang und flach hinter einem grün angestrichenen hölzernen Zaun.

Noch ehe sie sich überlegt hatte, ob sie eintreten wolle, war sie bereits aus einem Fenster des Erdgeschosses von derjenigen bemerkt worden, der ihr Besuch galt.

Kaum stand sie im steingepflasterten Flur, der die ganze Mitte des Hauses durchschnitt, als sich auch schon eine der vielen Zimmerthüren zu seinen beiden Seiten öffnete, und die ihr wohlbekannte energische Stimme auf russisch erfreut herausrief: »Willkommen! Willkommen! Frau Marinka!«

Aus dem Hintergrunde des Flurs, wo dieser in ziemlich dunkle Küchenräume zu münden schien, quoll starker Dampf und Speisegeruch. Eine dralle Magd, mit aufgekrempelten Aermeln und in Bastschuhen, schlürfte vorüber.

Aber im Zimmer selbst, das Marianne betrat, war es, trotz seiner rohen grellbunten Tapete und den ungestrichenen Dielen, nicht unbehaglich. Wer hier eigne Möbel um sich aufstellen konnte, entbehrte nicht ganz eines gewissen Komforts.

Aus einem Sessel am Fenster hatte sich eine große, starkknochige Sechzigerin erhoben und ging Marianne belebt entgegen, wobei sie sich auf einen Stock stützte.

»Nun, meine Liebe, das ist wirklich aufopfernd von Ihnen, -- ich wäre Ihnen auch längst auf dem zugkalten Flur entgegengelaufen, aber, Sie wissen: die dumme Gicht! Und Doktor Tomasows Verbot! -- Setzen Sie sich, meine Einzige; was kann ich Ihnen anbieten: Thee, Obst, Schokolade, Konfekt oder etwa kaltes Rebhuhn?« -- fragte sie, in rascher, lebhafter Rede, mit der Miene einer Schloßfrau, die bewirtet; zugleich hob sie den Krückstock und deutete damit auf die verschiedenen Stellen im Zimmer, wo die angebotenen Herrlichkeiten ihren Platz gefunden hatten.

Marianne mußte lächeln, sie sah um sich. Ja, da standen in der That allerlei Leckereien, -- die guten Bekannten hatten sie gebracht.

»Ach, Wera Petrowna, das ist ganz gut, aber daß Sie hier wohnen müssen! Sie sollten es jetzt besser haben: hat Tomasow Ihnen von der neuen billigen Pension erzählt?«

Wera Petrowna lachte voll Nichtachtung und zeigte dabei ihre starken, gelblichen, wohlerhaltenen Zähne.

»Thorheit, meine Liebe, Thorheit!« sagte sie und zog Marianne neben sich auf das große, mit verblichener geblümter Wolle überzogene Sofa. »Von meinem winzigen Gelde kann ich auch in der billigsten Pension nicht leben. Armenstift, -- das ist Vorurteil. -- Und Konfekt und Rebhuhn, das ist ja recht schön, aber wenn meine Verwandten glauben, daß sie mich dadurch ködern und willfährig machen können, -- daß ich deshalb bei ihnen irgendwie als gute Tante unterkriechen würde! -- Ich esse einfach die guten Sachen, und komme doch nicht.«

Die Alte wußte ganz gut, welch schmerzlicher Stein des Anstoßes ihren ansehnlichen Verwandten ihr »Schloß« war, wie sie das Armenasyl nannte.

Sie nahm bedächtig eine Prise.

»Kommen Sie nicht vielleicht morgen zu uns zum Frühstück?« fragte Marianne. »Heute habe ich knapp Zeit, aber dann könnten wir von den Weihnachtseinkäufen plaudern. Ich weiß schon, daß Sie so gut sind, mir mancherlei Besorgungen abzunehmen, -- ich komme ja erst dicht vor Thorschluß dazu.«

Wera Petrowna nickte.

»Ja, so gut bin ich, -- sehr gern, thu ich sehr gern. Sie wissen ja, wie für mein Leben gern ich in den schönen Läden herumflankiere. -- Mit einigen blanken Rubeln oder ein paar Papierscheinchen lauter gute Dinge ansehen und bestellen, -- nun,

und die Verkäufer, die haben auch höllischen Respekt vor meinen scharfen Augen und müssen herzeigen, worauf ich mit dem Stock weise, -- und sollten sie sich selbst beim Hinundherklettern den Hals verrenken.«

»Aber reinen Mund vor den Kindern!« warnte Marianne.

»Natürlich. Freue mich recht, morgen die beiden wiederzusehen. Sah die Cita ja lange nicht. Und sie sind beide so recht hübsch zum Ansehen, -- nun, auch zum Sprechen gut, wirklich sehr gut. Schade, zu denken, daß so was bald weggeheiratet wird. Schade, schade.«

»Ganz so pessimistisch urteile ich darüber nicht, ein solches Fortgehn ist nicht das schlimmste Fortgehn,« sagte Marianne leise.

»Nun, ist vielleicht auch wahr. Wenn ich so denke, wie es mir erging. Verschlagen ins ärgste Gutsleben in entlegenster russischer Provinz -- vom ersten Tage der Ehe an. Und hineingekommen mitten aus der feinsten städtischen Erziehung, -- ja, alles, was wahr ist: mitten aus den feinsten Pensionaten und voll von allerlei Bildungsbedürfnissen. Und trotzdem -- was meinen Sie wohl? -- trotzdem hab ich doch diesen Menschen bis an seinen Tod angebetet, diesen prachtvollen Jungen, meinen Mann! Konnte er etwa mehr als Gutsarbeit, Trinken, Spielen --? Nein, keine Spur! Und brutal war er auch, wenn er nicht grade zärtlich war. Was that mir das alles? Tottreten hätt er mich dürfen! -- -- Nun ja, Leidenschaft ist blind und taub, das weiß man ja, -- und mitunter ist sie auch unglaublich dauerhaft dabei, -- das muß wahr sein. -- -- Die längste Zeit des Lebens ist man einfach verrückt.«

Es klang fast cynisch. Marianne kannte diesen Ton. Aber auch das kannte sie: daß Wera Petrowna dasaß und durch ihr lebhaftes Erzählen von irgend etwas Marianne von der Unterhaltung enthob, weil sie merkte, wie wenig Marianne, ihrer lieben »Marinka«, nach Unterhaltung zu Mute sei. Und was merkte sie nicht? Gewiß schon bei den ersten Begrüßungsworten hatten diese hellgrauen fast ironisch blickenden Augen alles, was sie wollten, gesehen.

Wera Petrowna griff nach einem frisch angebrochenen Zigarettenkästchen und machte Feuer.

»Geschenk von meinem Neffen!« bemerkte sie kurz. »Und Sie rauchen noch immer nicht? -- -- Wird auch noch kommen, meine Einzige, wird auch noch kommen. Wissen Sie überhaupt: alle wahren Genüsse kommen im Alter, -- und so weit sind Sie eben noch immer nicht, Sie Aermste. -- Da hat man nämlich erst die Ruhe dazu, -- ich meine: so die inwendige Ruhe. Man hat kälteres Blut. Taxiert die Dinge anders. Nimmt nicht alles so wahnsinnig persönlich, woraus ja doch allein alle schrecklichen Schmerzen kommen. -- Nun, ich will Ihnen übrigens alle diese spannenden Vorteile nicht vorweg erzählen, Sie erleben sie ja auch noch. -- Es ist wirklich zu schön, sagte der Bauer, und da ließ er sich zur Ader, so lange, bis er starb --.«

Sie lachte auf und rauchte wie ein Schornstein.

Marianne sah nach der Uhr.

»Jetzt muß ich zur Stunde,« sagte sie bedauernd, »also auf morgen. Wie gut und ruhig sitzt es sich bei Ihnen, man ruht aus.«

»Ja, mein Täubchen, wollten Sie nur noch bleiben, -- ich würde gern das Maul halten; übrigens, ich begleite Sie, wenn Sie erlauben. Fahre mit der Pferdebahn von der Ecke an in der Richtung der Schmiedebrücke. Ich habe, weiß Gott, hier nichts zu thun. -- Für gestern abend bekam ich richtig noch ein überzähliges Theaterbillett zugesteckt. Ein Lotterleben führt die Alte, was?«

Sie erhob sich schwerfällig und streichelte Marianne liebkosend die Wange.

»Ein Leben, um dessen Frische und Elastizität der Jüngste Sie beneiden muß,« versetzte Marianne, »wer von uns würd es an Ihrer Stelle wohl ohne Trübsal aushalten -- bei diesem Mangel an dem Ihnen gewohnten Behagen und Ueberfluß?«

Wera Petrowna hatte ihre Haube von dem ganz dünnen grauen Haar heruntergenommen und band sich umständlich einen wattierten Kapottehut, mit Ohrenklappen für den Wind, auf dem Kopf fest.

»Behagen? Da hust ich drauf!« antwortete sie derb, und es wetterleuchtete von Spott über ihren scharf geschnittenen Zügen; »was schert mich denn das bißchen Behagen? Eiderdaunen und Tischporzellan, fette Braten und Dienerschaft rechts und links, bis man sich nicht mehr rührt noch regt, sondern irgendwo einschläft. Mit all dem Behagen haben wir uns da hinten auf dem Gut gestopft, wie Mastgänse. Das Behagen quoll uns direkt zum Halse heraus. Aber das Leben stand mir still, -- all mein Leben, bis auf das eine verliebter Leute. Nun bin ich als Mastgans alt geworden, aber vom Leben will ich noch schnell was mitnehmen, soviel eben eine alte Gans noch begreift.«

Sie ließ sich von Marianne in ihren Pelz helfen, versorgte sich reichlich mit Zigaretten und klapperte mit ihrem Stock auf den steinernen Flur hinaus.

Sie gingen nur ein kleines Stück gemeinsam, bis zu der Pferdebahn.

»Sehen Sie, da kommt sie schon!« sagte Wera Petrowna mit innigem Vergnügen und wies mit ihrem Stock auf den herannahenden Straßenbahnwagen: »Und nun geht es für bloße fünf Kopeken mitten hinein in die Wagen und Menschen, Schauläden und Ausstellungen -- und sogar in die Unglücksfälle -- meinetwegen, wenn das Genick doch schon gebrochen sein muß.«

Marianne blieb lächelnd stehn, bis sie die Alte im Inneren des Wagens gut placiert sah, dann schritt sie schneller aus, zu ihrer Privatstunde.

Die Eindrücke des heutigen Nachmittags zu Hause traten dabei langsam in den Hintergrund, und die Notwendigkeit, alles zurückzudrängen, was sie nicht in ihren Beruf mitbringen durfte, erwies sich, wie so oft, heilsam befreiend für ihre Stimmung. Als sie vom Unterricht zu ihrer Schwester ging, hatte ihre Grundnatur, getrost und tapfer, bereits wieder den Sieg über die Traurigkeit gewonnen.

Es war schon halb neun Uhr. Sie kam bei Ottilie grade noch zum Abendthee zurecht. Neben dem Tisch im Eßzimmer dampfte schon der silberne Samowar auf seinem Gestell, die Theegläser standen bereit und dazwischen flache Schüsseln mit eingekochten Früchten und mit winzigen belegten Brotschnittchen, -- jedes grade ein Mundvoll groß, fast so zierlich wie Konfekt hergerichtet.

»Aber seid ihr etwa nicht allein heute?« fragte Marianne beunruhigt, als sie diese kunstvollen Zuthaten zum Abendthee wahrnahm und die hübschen gestickten Tellerservietten, -- Ottiliens eigne mühsame Handarbeit.

»So gut wie allein,« versetzte ihr Schwager, der sie empfangen und hereingeführt hatte, »Ottilie sitzt nur noch drinnen mit einem Fräulein -- eine ausländische Konzertsängerin, glaub ich --. Jedenfalls schwärmt Tilie für das Fräulein Clarissa.«

Er machte bei seinen Worten ein gutmütiges, behagliches Gesicht. Ihm gefiel, wenn schon nicht die Konzertsängerin, so doch der um ihretwillen so schön bestellte Theetisch sehr gut.

Ueber die Schüssel mit den zierlichen Brotscheibchen gebeugt, steckte er eins davon, mit geräuchertem zartrotem Lachs belegt, in den Mund. Grade wollte er Marianne auffordern, sich der gleichen Beschäftigung hinzugeben, als seine Frau mit dem fremden Fräulein bereits eintrat.

Nun wurde nach den Kindern gerufen, man nahm geräuschvoll Platz und tauschte die üblichen Redensarten. Inotschka, die dreizehnjährige Tochter, erschien schüchtern an der Thür, sie machte vor der Fremden ihren eingelernten Knix mit einer Befangenheit, die sie linkisch aussehen ließ und die schlanke Grazie ihrer feinen Bewegungen ganz verwischte.

Rot bis an den lichtbraunen Haarschopf über ihrer Stirn, setzte sie sich in ängstlicher Haltung neben ihre Mutter, deren Stirnrunzeln sie schon bemerkt hatte. Aber dabei flog ihr Blick mit einem Aufleuchten zu Marianne hinüber, die von ihr in all der Verlegenheit nicht einmal begrüßt worden war. Dafür grüßten sie ihre Augen nun fortwährend und brachten dadurch ihr Theeglas in Gefahr, von den unachtsamen schmalen, rötlichen Händen umgestoßen zu werden.

Nikolai, der älteste Sohn, ein großer Junge in der kleidsamen Gymnasiastenuniform, saß neben Marianne, mit der er sich ebenfalls besonders gut stand. An seinen freien Montagnachmittagen war er ihr Schüler, da trieben sie auf Wunsch des Vaters englische und französische Konversationsstudien, und bei diesen Gelegenheiten hatte er mit vielen grammatikalischen Fehlern Marianne mehr von seinen vierzehnjährigen Wünschen und Nöten anvertraut, als je auf gut russisch seinen eignen Eltern. Heute klagte er Marianne heimlich, mit ausdrucksvollen Andeutungen, sein Leid über diesen unerwarteten Damenbesuch; er wollte zu bestimmter Stunde einen Kameraden treffen, und nun konnte »die Geschichte schrecklich lange dauern hier bei Tisch«.

Seine beiden kleinen Brüder schauten hinter ihren breiten Milchtassen nur ganz verstohlen auf den fremden Gast in dem für einen simpeln Familienthee etwas zu prächtig geratenen Gesellschaftsanzug. Sie waren beide beängstigend artig, -- so artig, wie, nach Mariannens in diesem Punkt ziemlich trüben Lebenserfahrungen, lebhafte Kinder nur dann sind, wenn sich bald darauf etwas Fürchterliches ereignet.

Aber diese Kleinen hier regierte auch bei Tisch der wachsame Blick ihrer Mutter mit unmerklicher Strenge. Der Jüngste, Mariannens Liebling, war schon zu Bett.

Ottilie verstand es musterhaft, in sich stets gleichbleibender Liebenswürdigkeit sowohl für die Unterhaltung wie für das Betragen der Kinder zu sorgen. Und während sie emsig ihrem Mann den Thee auf seine ganz spezielle Weise mit Fruchtgelee anrührte, blieb sie doch ganz Ohr und fiel bei jeder heitern Aeußerung ihres Gastes mit einem kleinen hellen, klingenden Lachen ein.

»Sie ist darin einfach bewunderungswürdig!« dachte Marianne aufrichtig, die inzwischen ganz still geworden war. Sie hatte genug damit zu thun, gegen ihre Abspannung anzukämpfen, von der sie an solchen Tagen, beim ersten Nachlassen von Pflicht oder Freude, überfallen werden konnte.

Hin und wieder verschwammen ihr die Worte der andern in einem eintönigen Gesumm. Sie wußte sich sogar ganz gut im stande -- zu ihrer eignen Beschämung --, auf diesem bequemen Stuhl mitten unter ihnen allen recht tief und süß einzunicken, um dann zu einer gegebenen Zeit frisch und heiter zu erwachen, von neuem aller ihrer Kräfte Meister --.

Erschrocken bemühte sie sich, besser zuzuhören. Fräulein Clarissa schwärmte soeben von Oesterreich.

»Das ist ganz Wasser auf die Mühle meiner Frau!« sagte der Schwager. -- »Die ist ganz versessen drauf, und nun gar Wien! -- Hier ist nur das Diesseits, dort das schönere Jenseits: so etwa denkt sie sichs. Und die Praterfahrten, und die feschen Offiziere, -- nicht wahr, Tilie?«

Er sprach mit gutmütigem Spott, Stockrusse, wie er durch und durch war, kaum je über die Landesgrenze gekommen, und vielleicht zu seiner eignen Verwunderung mit einer halben Nichtrussin verheiratet. Sein naiver Chauvinismus kam seiner Karriere als höherer Beamter sehr zu statten, war indessen intensiv ehrlich gemeint.

Ottilie erwiderte gar nichts. Doch hatten sich alle Züge ihres Gesichtes während seiner Worte verändert, strafften sich plötzlich, -- es sah aus, wie wenn sie sich auf Eis legte. Die Theekanne zitterte leicht in ihrer Hand.

Nur Marianne bemerkte es. Ganz erstaunt sah sie die Schwester an. Ach so, -- der fesche Offizier?! -- Nein, das konnt es doch wohl nicht sein? Ein österreichisch-ungarischer schmucker Husar, Leichtfuß und nichtssagend, hatte Ottilie einst einen Heiratsantrag gemacht -- in gänzlicher Verkennung der materiellen Verhältnisse. Eine belanglose Schwärmerei Ottiliens. Wie belanglos, das empfand Marianne damals doppelt deutlich gegenüber ihrem eignen Bündnis, das sie kurz zuvor eingegangen war.

Sie erinnerte sich noch ganz gut, wie heftig der zigeunerische Teint und die Husarentracht die Schwester bestachen. Und um wie viel älter sie sich selbst urplötzlich daneben vorkam. Um so viel älter wie erglühende inbrünstige Jugend neben den Gefühlswallungen der Backfischentwicklung.

Ottiliens Mann hatte die Bedeutung dieses ominösen Husaren offenbar rein vergessen. Ottilie hatte sie jedoch sonderbarerweise hinter ihrer ruhigen, liebenswürdigen Verschlossenheit ganz und gar nicht vergessen. Der Schwager schien nicht allzuviel Ahnung von den geheimen »Tiefen« in seiner Frau zu haben.

Nikolai rückte immer unruhiger auf seinem Stuhl herum und schielte nach der großen Wanduhr gegenüber. Er wagte aber nicht, aufzustehn. Der Blick seiner Mutter, der jetzt um eine Nuance schärfer und gereizter schien als vorher, mahnte ihn wiederholt daran, daß auch er einen, wenn auch nur bescheidenen Beitrag zur Unterhaltung zu liefern habe, weil es sich für seine Jahre schicke, die Umgangsformen zu üben.

Nikolai zermarterte sein Gehirn. Ihm kam eine entsetzliche Menge von Gedanken und Vorstellungen, aber sie waren alle so merkwürdig unpassend.

Schon war er nahe daran, bei Tante Marianne einen kleinen Gedanken zu borgen. Da fiel ihm grade noch etwas ein, und er sagte ganz verzweifelt, -- viel zu laut mitten hinein ins Gespräch der übrigen: »In unsrer Schule ist ein Junge für immer abhanden gekommen.«

»Wie denn abhanden gekommen?« fragte Marianne befremdet.

»Ja so, ganz abhanden. Er war dort Pensionär, lief fort und hinterließ einen Zettel, daß er sich töten wolle. Niemand weiß, wo und was. Seine Eltern leben in Südrußland. Man hat ihn noch nicht aufgefunden.«

Ein kleiner Alarm entstand am Theetisch. Nikolai war ganz stolz. Alle redeten durcheinander.

»Mein Himmel, daß du das auch nicht gleich erzählt hast!« rief sein Vater.

Nikolai nahm sich das heimlich bereits für das nächste Mal vor, wenn wieder ein Junge abhanden kommen sollte. Er hatte gefürchtet, es sei im Hinblick auf einen Gast ein zu bescheidener Beitrag.

Ottilie seufzte. Sie sah streng und bitter aus.

»Das sind Zustände!« bemerkte sie empört. -- »Ja, wenn schon die Kinder so anfangen! Dann ist es freilich nicht zu verwundern, wenn sie sich ohne alle Zucht und Sitte erst recht töten, nachdem man sie glücklich bis zum Erwachsensein durchgebracht hat. Was für ein Kind muß das gewesen sein, das so etwas Schändliches thut.«

»Und welch eine Behandlung, die so etwas ermöglicht!« setzte Marianne im stillen hinzu. Sie erschauerte. Konnte man sich wohl je genügend tief in eine Kinderseele hineindenken, die zu solchen Entschlüssen gelangt war? Vielleicht bezwungen vom Heimweh, -- von irgend einer unverstandenen Angst, -- Angst vor dem ganzen Leben selbst vielleicht, -- wer weiß es denn?

Und ihr wurde das Herz ganz weit und groß, als müßte sichs über eine Welt ausdehnen und alle Kinder darin umfassen, -- mit solcher Wärme und Inbrunst umfassen, daß keins davon ausgeschlossen bliebe.

Ganz verträumt und zerstreut stellte sie sich vor, wie es wäre, wenn sie jetzt hingehn könnte und suchen und finden, und wie das ratlose Kind, anstatt in irgend eine letzte Dunkelheit, sich hinein verfangen würde in helfende, starke, mutterzärtliche Hände --.

Endlich erhob man sich.

Nikolai entfloh. Die kleinen Brüder machten ihre Runde mit einem schläfrigen, etwas schwankenden Kratzfuß und wünschten gute Nacht. Im Nebenzimmer wurde der schöne Flügel geöffnet, und Fräulein Clarissa setzte sich davor, um ein Arie aus Figaros Hochzeit vorzutragen.

Marianne griff der Gesang an. Die Stimme, ein prachtvoller Alt, erwies sich als zu groß für das nicht sehr geräumige Zimmer. Ottilie ließ sich augenscheinlich nicht weiter davon anfechten, übrigens war sie auch nicht sonderlich musikalisch.

Der Schwager setzte sich zu Marianne. Er schob ihr ein bequemes Kissen in das Sofa, dessen Polsterlehne im Rücken unbequem einfiel, und warf seine Zigarette fort. Etwas so Sorgliches besaß er.

»Findest du nicht: Tilie sieht schön und vorteilhaft aus, sogar neben der viel Jüngern, -- ihr seid eine dauerhafte Rasse, ihr beide!« bemerkte er mit einem freudigen Blick auf seine Frau, die am Flügel stand.

»Ja. Ich bewunderte sie heute wiederholt,« gestand Marianne.

Er nickte eifrig.

»Einfach famos!« Und er versank in Gedanken über die Vorzüge seiner Frau, die er aufrichtig liebte.

Inotschka hatte sich hinter das Sofa geschlichen, gegen das sie sich lehnte, indem sie ihre Arme auf seiner Rückseite verschränkte, sodaß sie Mariannes Haar berührten.

Marianne gab leise nach und legte den Kopf zurück an die magern zärtlichen Mädchenarme, von denen sie wußte, wie viel lieber sie sie herzhaft umhalsen würden.

Immer hatte sie an sich gehalten, wenn sie spürte, daß ihr Inotschkas Vertrauen entgegenflog, denn sie durfte sie nicht der Mutter wissentlich entfremden.

Dadurch wurde der Wortaustausch zwischen ihnen wunderlich einsilbig und karg. Doch beredter als Worte schlich sich eine feine leise Zärtlichkeit ergänzend in ihren Verkehr, kaum wahrnehmbar andern, kaum merklich ihnen selbst --.

Marianne dachte: »-- Wenn Inotschka erst älter und reifer ist, dann wird sie mir auch mehr zugehören dürfen. Ueber diese paar Jahre muß sie hinweg, wie so viele --.«

Und sie dachte dankbar daran, daß in diesem Alter nicht viele so ganz eins im Sinn und Sein mit der eignen Mutter sind, wie es Cita und Sophie mit ihr gewesen waren.

Darüber fiel ihr der heutige Nachmittag wieder ein --.

Aber sie wollte nicht wieder zaghaft werden: diese Zeit der innigsten Zueinandergehörigkeit konnte nicht vorbei sein. Wußte doch sie am allerbesten, wie viel, wie unendlich viel sie ihren Kindern noch gar nicht gegeben, noch gar nicht mit ihnen geteilt hatte, weil sie auch jetzt noch zu jung und unerfahren waren, um alles zu empfangen. Voll Freude und Ungeduld ersehnte sie die Zukunft, wo ihnen einmal alles, ihr ganzer tiefster Lebensgewinn, zu eigen werden durfte. Wo sie einander ganz verstanden und durchdrangen, wie drei Freunde, -- um miteinander eine unzertrennliche seelische Einheit zu bilden. Dann erst würden alle ihre Schmerzen und Erfahrungen, alle ihre Kämpfe und Siege kostbare Ernte tragen, -- eine Ernte auf den Feldern ihrer Kinder --.

Marianne bekam Heimweh nach ihren beiden Mädchen, es trieb sie aus dem heißen Zimmer nach Haus.

Als sie endlich mit gutem Anstand fortgehn konnte, war es über dem Singen elf Uhr geworden.

Die Begleitung des Schwagers schlug Marianne aus. Sie schlich sich nur noch für einen Augenblick in die große Schlafstube, um das jüngste Bübchen in seinem Gitterbett schlummern zu sehen, was sie nie zu thun unterließ.

Dann gab ihr Inotschka das Geleit bis auf die Treppe hinaus.

»Wann kommst du denn wieder zu uns, Tante Marianne?« fragte sie ganz zum Schluß und lehnte sich über das Treppengeländer.

»Sehr bald, mein liebes Kind, -- ich komme ja schon übermorgen wieder, zu Nikolais Konversationsstunde,« antwortete Marianne.

Inotschka schwieg eine Weile, aber als Marianne schon hinunterging, bemerkte sie zögernd: »Weißt du, -- ich sticke Pantoffeln für Mama zu Weihnachten.«

»So? Bist du noch nicht mit den Weihnachtsarbeiten fertig?« fragte Marianne.

»Nein, nicht ganz. Da dachte ich, -- mit dem Pantoffel könnte ich mich gut in unsre Lernstube setzen, während du bei Nikolai bist --. Meinst du nicht auch?«

Marianne sah zu ihr hinauf.

»Gewiß, wenn Mama nichts dagegen hat? Aber du mußt sie lieber erst fragen.«

Inotschka nickte schweigend.

»Gute Nacht, meine kleine Ina!« rief Marianne ihr noch zu, während sie schon die letzte Treppe hinabstieg.

Indessen Inotschka antwortete noch nicht gleich, sie bückte sich nur tiefer über die Brüstung, und erst als sie nicht mehr wissen konnte, ob ihre Worte von unten her noch vernehmbar wären, rief sie zaghaft, mit gedämpfter Stimme, und ganz hastig hinunter: »Gute Nacht! Gute Nacht! Ich muß dir doch noch schnell sagen, daß ich dich ganz schrecklich lieb habe, und daß du mich fortnehmen sollst zu dir, und daß ich immer bei dir sein will und nirgends sonst. Und daß du mich nicht so stehn lassen sollst -- nicht so allein --.«

Sie brach ab. Schon während der ersten Worte schloß der Portier unten geräuschvoll die Hausthür auf, die dann mit einem mächtigen Knall zuklappte.

Im Treppenhause wurde es plötzlich so beängstigend still.

»Sie hat nichts gehört, -- gar nichts hat sie gehört. Das ist mal gut. Unsinn, -- wozu auch!« sagte Inotschka wesentlich lauter als vorhin.

Aber obwohl sie es gut fand, daß Marianne nichts mehr vernommen hatte, verfinsterte sich ihr schmales Gesichtchen mit dem weichen Munde. Sie drückte die Zähne auf die Lippen und rieb sich mit blinzelnden Augen, um nicht loszuweinen, am Geländer, bis die Stimme der Mutter von drinnen in erstauntem Ton nach ihr rief.

=III.=

Seit zehn Uhr waren die jungen Mädchen von ihrer Schlittenfahrt im Sternschein zurück.

Cita saß schon eine Weile auf dem Rande ihres weißlackierten Eisenbettes und zog sich bedächtig die Strümpfe von den hübschen Füßen.

Sophie ging noch unausgekleidet umher, sie machte sich bei ihren Büchern zu schaffen, die sie auf ihrem Tisch am Fenster aufzustapeln pflegte, und etliche von ihnen trug sie ins Wohnzimmer auf den Schreibtisch der Mutter hinüber.

Dabei sprach sie kein Wort. Sie war schon den ganzen Abend gegen ihre Gewohnheit still gewesen und behielt auch jetzt die Miene einer düster Versonnenen.

Cita legte gähnend ihre Strümpfe auf den Stuhl am Bett.

»Schlittenfahren ist ganz schön,« entschied sie, »aber dies gesellige Vergnügtsein von Männlein und Weiblein, die nichts Besseres zu thun wissen, -- wie bin ich froh, daß ich mich davon gründlich entwöhnt habe! Kindisch ist es einfach. Es gibt doch wahrhaftig ernstere Aufgaben in der Welt.«

»Meinetwegen kann es auch aufhören,« versetzte Sophie apathisch, mit einer bekümmerten kleinen Stimme, »und auch das Schlittenfahren, und überhaupt alles.«

Sie kam eben wieder aus dem Wohnzimmer zurück. Cita fragte gar nicht, was sie dort eigentlich treibe, sie wußte gar nicht, daß Sophie soeben ihre Studienbücher und Lieblingswerke auf Mas Schreibtisch aufgeschichtet hatte, wie man sündhafte Kostbarkeiten auf einen Scheiterhaufen trägt.

Sie wollte Ma so gern nach der heutigen Kränkung ihre rückhaltlose Ergebenheit beweisen. So gern ihr zeigen: »Siehst du, ich entsage allem, was mich von hier fort zu locken anfing! Schließe es für immer vor mir zu.«

Aber Cita brauchte das einstweilen noch nicht zu wissen. Denn Sophie fürchtete sich entsetzlich davor, ihr eignes Thun klar und endgültig aussprechen zu hören.

Sonst hätte sie es noch am liebsten heute abend Hugo Lanz anvertraut. Ja, dem am ehesten! Sie meinte: wenn er zum Beispiel, davon erschüttert, nun auch seinerseits alle ehrgeizigen Pläne fahren ließe, dann hätten sie gemeinsam trauern, sich gemeinsam trösten und ermannen können.

Er würde dann kein Dichter werden, sondern ein Kaufmann, und sie kein Arzt, sondern -- sondern vielleicht irgend wann einmal die Frau eines Arztes, Dichters oder Kaufmanns in der Welt.

»Geh doch endlich schlafen!« rief Cita in ihre schwermütigen Betrachtungen hinein. Sie selbst lag bereits im Bett, grade auf dem Rücken ausgestreckt, die Arme über dem Kopf verschränkt.

Sophie setzte sich zu ihr auf die Bettkante.

»Glaubst du, daß es glückliche Ehen gibt?« fragte sie langsam und ernst.

Cita gähnte gleichmütig.

»Ja,« versetzte sie nach kurzer Ueberlegung, »aber entschieden nur unter den Frauen, die sich unsrer Frauenbewegung anschließen. Das ist sonnenklar: denn die setzen sich in den Stand, sich selbst zu versorgen, den Mann nicht zu brauchen. Also kann es die schlimmste Eheschließung überhaupt nicht mehr geben: nämlich die wegen Geld und ohne Liebe. Dafür sind andre, schönere nun erst möglich, --«

»Zum Beispiel sogar ohne Geld und mit Liebe!« fiel Sophie hoffnungsvoll ein. Wie schön war das eigentlich! Aber davon schloß sie sich auch aus, wenn sie nicht Arzt wurde, -- kein selbständiger, erwerbender Berufsmensch.

Cita sagte plötzlich leise: »An die ganze Heiraterei mag ich aber einstweilen weniger als je denken. -- -- Weißt du, es hat etwas so Schreckliches: man ist keines Menschen sicher, -- jedem kann noch einfallen, das Verrückte zu thun und zu heiraten. -- -- Stell dir zum Beispiel vor, daß unsre Ma -- --«

Sophie stellte es sich nicht vor. Sie schüttelte den Kopf und lachte.

»Schäm dich,« sagte sie kurz.

Cita richtete sich im Bett auf. Ihre dunkeln Augen hefteten sich erregt und finster auf die Schwester.

»Nein, nein, glaube mir! Ich behaupte nur, daß so etwas möglich ist, -- nichts weiter. Aber möglich ist es. Es ist möglich, es ist möglich.«

Der Ton, in dem sie es wiederholte, wurde immer härter und kälter. Nach einer Pause fuhr sie fort: »Und wer könnte auch was dagegen thun, dagegen sagen? Schließlich ist es doch das Recht eines jeden Menschen -- --. Auch Mas Recht also, -- -- jawohl, unsrer Ma auch, die bis jetzt so ganz ausschließlich uns gehörte, -- ganz allein _unsre_ Ma war, an die niemand sonst den geringsten Anspruch machen darf. Niemand, niemand --«

»Nein, niemand!« bestätigte Sophie gedehnt. »Niemand außer uns --«

»Es ist aber ihr gutes Recht! Vergiß nicht: ihr gutes Recht!« fiel Cita nachdrücklich ein. »Von uns ist es ganz unberechtigt, so zu sprechen. Ja, vollständig. Mama kann jeden Tag heiraten, wenn sie will, -- und überhaupt thun und lassen, was sie will --«

Sie brach ab. Ihre Stimme vibrierte von verhaltener Erregung.

Sophie stand auf und küßte die Schwester flüchtig auf die Stirn.

»Gute Nacht. Schlaf lieber. Du bist einfach verrückt geworden. Ich glaube, du träumst schon!« erklärte sie. »Ebensogut könnte ich mir vorstellen, daß Ma überhaupt gar kein Mensch, sondern ein Walfisch ist.«

Mit diesem Bescheid kehrte sie ins Wohnzimmer zurück und setzte sich an den Schreibtisch vor die aufgeopferten Bücher. Oben drauf hatte sie das Mikroskop gestellt, das sie erst vorigen Weihnachten zum Geschenk erhalten hatte. Nun war es eine ganze Pyramide von Sachen.

Eigentlich wollte sie Ma hier erwarten. Es sollte keine Nacht drüber hingehn und sie wankend machen und auf andre Gedanken bringen --.

Seltsamerweise fiel ihr wieder Hugo Lanz ein. Ja, wer weiß: indem sie dem erwählten Beruf entsagte, entsagte sie vielleicht sogar einer jener allein glücklichen Eheschließungen, die Cita noch gelten ließ. -- -- Denn Hugo Lanz besaß kein Geld -- --.

Also war es wirklich ein Totalverzicht. Ein Opfer der Kindesliebe, wie es nicht bald ein zweites gab.

Sophie saß beim Schreibtisch mit gefalteten Händen und den gemischten Gefühlen einer über ihre eigne Größe fast bis zur Verlegenheit erstaunten Märtyrerin.

Cita hatte inzwischen ihren Rat befolgt und war in gesunder Müdigkeit nach der langen Fahrt durch die Winterkälte fest eingeschlafen. Aber sie lag da mit finster zusammengerückten Augenbrauen und einem bösen Ausdruck um den Mund.

Die zurückgedrängte Bitterkeit in ihrem Herzen hatte noch ihre Schrift auf ihr Gesicht geschrieben. Ihr letzter klarer Gedanke war das Gelübde gewesen, mehr als je ganz allein auf sich selbst stehn zu wollen.

Doch als sie in das Land der Träume hinüberglitt, senkte sich dichter und dichter eine große Finsternis um sie. Sie schaute vergebens nach den Dingen aus, die ihr vertraut gewesen waren, nach den Stätten, an denen sie sich heimisch fühlte. Eine schwarze Wand wehrte ihr Durchgang und Ausblick.

Und da überfiel sie Angst, wie sie nur als kleines Kind Angst gekannt hatte.

Beide Hände legte sie vor die Augen, um wenigstens das Dunkel nicht zu sehen. Doch was sie nicht sah, das fühlte sie: wie alle Gegenstände und alle Fernen über sie her kamen, wie sie sich zusammenrotteten und ballten, um sie zu ersticken --

Da entrang sich ihr in dumpfem Entsetzen Mas Name. Mit leiser, furchtsamer Stimme rief sie nach Ma. War denn nicht auch Ma irgendwo unter all dem da draußen, was sie umdrohte und gefährdete? Dann würde sie alles entwirren, alles Böse abhalten --.

Aber Ma war nicht da.

Und plötzlich wußte sie, daß Ma nicht mehr da war, -- das allein, nur das war die Finsternis ringsum -- --.

* * * * *

Gegen Mitternacht fuhr ein Schlitten vor.

Marianne stieg die Treppe hinauf und öffnete so geräuschlos wie möglich die Thür zur Wohnung.

Alles blieb still. Also schliefen die Kinder bereits. So ging sie leise hinüber in ihr nach dem Hofe gelegenes Schlafzimmer neben Sophiens und Citas Stübchen.

Hier hatten zärtliche Hände schon für alles gesorgt. Die Lampe angezündet, die warmen Vorhänge vor dem Fenster zugezogen, jedes Ding bequem bereit gestellt, von der Wasserkaraffe auf dem niedrigen Tischchen bis zu den tiefroten, kleinen Tuchpantoffeln vor dem aufgeschlagenen weißen Bett.

Neben der Karaffe stand am Bett ein schmales Kelchglas mit einer Handvoll italienischer Anemonen darin, -- blaßrote, violette, gelbe --, -- ein wenig angewelkt noch von dem Weg hierher.

Die Blumen mußten die Mädchen heute abend bei den Bekannten geschenkt bekommen haben. Und sie wußten, warum die Mutter diese Erinnerungen an Italien und seine Sonne so leidenschaftlich liebte --.

Marianne hob die angewelkten Stengel behutsam einzeln aus dem Wasser und beschnitt sie unten etwas, damit sie besser saugen möchten. Dann ordnete sie sie neu, mit Bewegungen, die sie fast liebkosten.

Die feine kleine Freude machte sie warm und wach. Ach, daß die beiden schon schliefen, die Langschläfer! Jetzt hätte sie sich gern noch auf einen Augenblick an ihre Betten gesetzt und sie geherzt.

Ihr war so kindfroh und bewegt zu Mut.

Als sie das Licht angezündet hatte und die Lampe herausstellen und auslöschen wollte, bemerkte sie einen hellen Schein in der Thürritze des Wohnzimmers.

Hatten sie die grüne Studierlampe brennen lassen? War doch noch eine von ihnen wach?

Sie glitt in die Tuchpantöffelchen und ging leise über den Gang zurück. Die Thür war nur angelehnt, sie stieß sie auf, um einzutreten.

Aber jählings hielt sie inne. Sie sah Sophie am Schreibtisch sitzen, die Arme auf den Büchern verschränkt, den Kopf mit den halb offen niederhängenden Flechten darauf, -- fest schlummernd.

Sie sah die Bücher, das Mikroskop, -- und das Gesicht sah sie, das ihr im Profil zugekehrt lag, hell bestrahlt vom Schein der Lampe.

Es war naß von Thränen. Die Mundwinkel wie im Weinen herabgezogen, die Augenbrauen so rührend im Ausdruck, so hilflos --. Ein so bekümmertes, schmerzliches, -- ein fast gramvolles kleines Gesicht!

Ja, hier mußte Sophie auf die Mutter gewartet haben, aus irgend einem Grunde. Gewartet mitsamt allen ihren Büchern, die sie hier aufeinander getragen hatte. Vielleicht um etwas zu erbitten? Vielleicht um zu sagen: »Sieh doch, wie lieb mir das alles geworden ist, wie gern ich frei sein möchte und mich dem widmen!«

Vielleicht auch, um etwas abzubitten. Um zu sagen: »Nimm es alles fort von mir, ich gebe dirs zurück, denn es weckt in mir die Sehnsucht, von dir hinwegzugehn.«

Und nun war sie unter Thränen hier eingeschlafen, wie ein müdes Kind, und nur dies traurige, kleine Gesicht erzählte der Mutter von ihren Nöten --.

Marianne stand noch in der halboffnen Thür, den Kopf gegen den Thürrahmen zurückgelehnt. Ihre Hände hingen schlaff an ihr herunter.

Was half es, daß sie fortgewesen, daß sie getroster und freudiger heimgekehrt war. Zu Hause trat es ihr wieder entgegen, das Gefürchtete, -- wie ein Gespenst.

Und mit diesem Gespenst trat ihr die liebste Gestalt entgegen, sie, von der sie es nicht ertrug.

Konnte die Mutter denn gewähren, was ihr Liebling von ihr heischte? Konnte sie denn wirklich auch die letzte fortlassen? Ganz, ganz allein nachbleiben? Mußte das sein?

»Nein! Nein!« schrie es in ihr.

Und mit Blitzesklarheit nahm die Erkenntnis ihr Herz ein: »Wenn du jetzt -- jetzt gleich sie wecktest, wenn du vor dein Kind hintreten würdest wie vor eine Ertappte, die du heimlich belauscht, -- wenn du ihre kleine schmiegsame Mädchenseele jetzt in die Hand nehmen und nach deinem stärkeren Willen prägen würdest: ja, dann wäre es vielleicht möglich, deinem Einfluß in ihr Gewalt zu verleihen. Nimm den Augenblick wahr, wo sie, sich selbst verratend, daliegt, als sei sie dir ausgeliefert. Mache sie zu deinesgleichen, hauche ihr dein Wesen und deine Wünsche ein. Sie ist ja dein. Sie vertraut dir grenzenlos, und ihr höchster Maßstab bist du. Nutze deine Macht über dein Kind --.«

Aber noch während Marianne deutlich ein jedes dieser Worte in ihrem Innern vernahm, als raune irgend wer sie unablässig ihr zu, machte sie eine übermenschliche Anstrengung, sich ebenso unbemerkt zu entfernen, wie sie hergekommen war.

Nur jetzt keinen Laut! Nur jetzt leise, leise hinweg, ehe sie erwacht, ehe sie ahnt, wer hier gestanden und mehr, als sie sagen wollte, von ihr erfahren hat --.

Es gelang Marianne, die Thür wieder anzulehnen und geräuschlos ihr Schlafzimmer zu erreichen.

Mechanisch begann sie, sich zu entkleiden.

Da standen noch die Anemonen.

Marianne blickte mit heißen Augen auf sie.

Dann löschte sie die Kerze aus.

Unerwartet, dicht, ohne den kleinsten Lichtfleck von draußen, den die zugezogenen Vorhänge am Fenster aussperrten, umhüllte sie das Dunkel wie eine Gruft.

Sie stürzte vor dem Bett in die Kniee und verbarg ihren Kopf in den Kissen --.

* * * * *

Dieser Sonntag war kein Sonntag zum Ausschlafen gewesen. Sowohl Marianne als die Kinder erschienen am Morgen übernächtig und mit übermüdeten Augen.

Keines von ihnen dreien wußte indessen etwas von dem eigentlichen Grunde der Traurigkeit in der Seele des andern. Cita schwieg, ihr war wunderlich weich, als ob ihr allerlei nächtliche Träume nachgingen, aber auch ihre Befürchtungen waren noch in ihr und stimmten sie reizbar, obgleich sie sichs auszureden suchte.

Marianne bemühte sich, vor den Augen der Kinder wohlgemut zu erscheinen. Als Sophie hereinkam, sagte sie freundlich: »Ich sehe, du hast gestern meinen Schreibtisch für deine Beschäftigungen auserkoren. Das ist recht so, ich gebrauche ihn jetzt in der Weihnachtszeit ja nicht. Und Cita wird vielleicht etwas stark Anspruch an den deinigen machen.«

Sophie errötete lebhaft, ohne zu antworten. Sie wußte nur noch dunkel, auf welche Weise sie gestern schließlich zu Bett gekommen war. Und es kam ihr im nüchternen Morgenlicht unmöglich vor, der Mutter die großen Eröffnungen zu machen. Jedenfalls lag es an der Nacht, daß diese Dinge ihr wesentlich leichter und natürlicher erschienen waren.

Das Dienstmädchen Stanjka, das sich zum Kirchgang rüstete, war die einzige, die sonntäglich und unbeschwert zwischen ihnen herumging. Sie trug ein neues grellrot gemustertes Kattuntuch um den Hals und hatte ihr aschblondes Haar mit Kwas glänzend gemacht; der Sonntag gehörte ihr fast immer, und sie freute sich auf ihn während der ganzen Woche.

Alles Gute war augenscheinlich immer auf einen Sonntag gefallen: in den Kirchen, in den Häusern, in den Vergnügungslokalen und Theebuden feierte man nur ihn! Die Glocken, die mit mächtigen Klängen die Luft erfüllten und in die Stuben hineintönten, redeten Stanjkas frommer Naivetät ganz unterschiedslos von himmlischen wie von irdischen Herrlichkeiten, von Kniebeugungen bei Orgelklang und Kirchengesang, wie vom Tanz zur Balalaika.

Nach dem Gottesdienst brauchte sie nur noch um zwölf Uhr den Frühstückstisch zu richten und den Samowar aufzustellen.

Kurz vorher erschien Wera Petrowna zur festgesetzten Stunde.

Sie hatte ein altmodisches und durch langen Gebrauch reichlich leuchtend gewordenes schwarzes Seidenkleid angezogen und trug auf dem Kopf eine komplizierte Haube mit lila Tolle, die sich im wattierten Kapottehut auf keine Weise unterbringen ließ, und die sie daher stets in einem besondern Beutel mit sich führte.

»Um ein Haar wär ich nicht gekommen, ich sollte nämlich heute vormittag in das Dawydowkonzert,« erklärte sie, als sie sich zu Tisch setzten. »Das Billet war noch nicht da, ich wartete drauf bis halb zwölf, es kam jedoch nicht. Es sollte nämlich nur dann kommen, wenn die Frau meines Neffen, die sich gestern abend schon unwohl fühlte, über Nacht krank würde. Sie ist aber nicht krank geworden.«

Sophie mußte lachen.

»Dafür ist es freilich kein Ersatz, wenn wir Ihnen später etwas vorspielen und vorsingen wollen,« meinte sie und legte Wera Petrowna von den kleinen Pasteten mit gehacktem Fleisch und Kohl vor.

»Nein, meine liebe, schöne, kleine Sophie. Auch muß ich später ohnehin fortgehn, denn ich habe noch andre Billete. Die habe ich mir eben geholt. Später drängen sich die Menschen so an der Kasse. Es ist weit besser, man ist versorgt.«

»Wohin denn?« fragte Cita ohne Neugier. Sie kannte die Ausgehewut und Belustigungssucht der Alten.

»Diesmal nur zur behaarten Riesin und zum zweiköpfigen Kind,« sagte Wera Petrowna gelassen und nahm sich Citrone zum Thee.

»Sie sind doch immer kreuzfidel, -- aber wirklich immer!« bemerkte Cita nachsichtig.

»Kreuzfidel? Nein, ihr junges Volk, das bin ich gar nicht. Ich muß mich nur beeilen, die Augen aufzureißen, ich habe viel nachzuholen. Wie lange dauert es, dann heißt es: Mund zu und Erde auf die Augen. -- -- Nun, hoffentlich dauert es noch ein Weilchen,« ergänzte sie.

»Nachholen? Ja, -- aber -- die behaarte Riesin --?«

»Nun, wenn auch nur eine Riesin. Was meinen Sie denn, ob bei uns dahinten auf dem Gut auch nur so eine gewesen wäre?! Nein, keine Spur! Das wäre ja Sensation genug für lange hinaus gewesen. -- Natürlich gibt es auch noch was Besseres als das. Natürlich. Man muß aber zufrieden sein, wie es sich trifft; die besseren Treffer kommen auch noch.«

Sie konnte es den jungen Mädchen gut anmerken, daß sie nicht mehr recht wußten, ob sie sich selbst ironisiere, oder ob sie von ihr zum Narren gemacht würden. Wera Petrowna gefiel das ausnehmend; sie betrachtete aus ihren klugen Augen die beiden Schwestern mit Wohlgefallen.

»Ja, ja, wenn ich auch noch so jung wäre. Herr du mein Gott!« sagte sie und schob den Teller zurück.

»Dann würden Sie sich ohne Zweifel noch weit besser und viel mehr amüsieren, nicht wahr?« äußerte Cita und zuckte bedauernd die Achseln. »Nun sehen Sie, daran liegt uns trotz aller Jugend gar nichts.«

»Nein, meine lieben dummen Unschuldstäubchen, -- ich würde ins Kloster gehen, ja, das würde ich!« behauptete die Alte, und ihr ganzes Gesicht lächelte fein und spitzbübisch aus allen seinen Fältchen. »Ja, davon habt ihr noch keinen Begriff,« fuhr sie auf der Mädchen erstaunten Blicke fort und nickte ihnen zu, »so eine Jugend, die geht ins Zeug! Nun, wohl bekomm's! Prosit Mahlzeit also!«

Sie stand auf, noch ehe Marianne, die geduldig dasaß und wartete, das Zeichen dazu gegeben hatte.

Marianne wollte ja mit ihr noch allerhand Weihnachtsbesorgungen besprechen. Und so viel sah sie recht wohl mit ihren beiden guten Augen: daß ihre liebe Marinka auch heute ein bedrücktes Herz haben mochte. Aus irgend einem Grunde, gleichviel aus welchem. Jedenfalls schienen heute selbst die Kinder dagegen machtlos zu sein, deren Geplauder die Mutter sonst heiter zu stimmen pflegte.

Ihr schien, daß sich Marianne nach Ruhe sehne, -- vielleicht nach einem Alleinsein, das die jungen Mädchen grade in ihrer zärtlichen Sorge vereitelten.

Als alles erledigt war, was zu besprechen gewesen, zog sie ihre Staatshaube vom Kopf und bestand darauf, fortzugehen. Aber schon im Mantel und Kapottehut mit zugebundenen Ohrenwärmern, klapperte sie noch einmal an ihrem Stock in den »Spalt« hinein, wo die Schwestern soeben an Stanjkas Statt den Tisch abgeräumt hatten.

»Also auf Wiedersehen, meine zwei Täubchen,« sagte sie, -- »wie ist es nun? Ich bin eine alte Frau, die am Stock humpelt -- in meiner Jugend würde man so eine nicht allein ins Menschengedränge haben gehn lassen, -- aber die junge Welt von heute --«

Cita und Sophie sahen sich verdutzt an. Sie blieben vor ihr stehn und machten verlegene Gesichter.

»Ja, warten kann ich nicht!« entschied die Alte und schwenkte aufmunternd ihren Beutel, »-- also, eins, zwei, drei: geht jemand mit mir ins Sonntagsvergnügen bei der behaarten Riesin und dem zweiköpfigen Kinde, -- und wer?«

Im edlen Wetteifer, nicht der andern die lästige Pflicht aufzubürden, riefen sie alle beide kleinlaut: »Ich!«

»Bravo! Bravo! Also alle beide!« lobte Wera Petrowna, und es zuckte dabei ganz wunderlich um ihre Mundwinkel, in Güte und Bosheit zugleich; »-- nun freilich! junges Volk ist eben junges Volk, wie ernsthaft es auch thut, da sieht man wieder: es will sich amüsieren.«

Marianne that es leid, als sie die beiden Mädchen betreten hinter der Alten fortgehn sah, indessen mochte sie ihr die so dringend provozierte Begleitung nicht mißgönnen. Ihr Kopf schmerzte heftig, sie hätte sich am liebsten mutterseelenallein in ein Zimmer mit verhängten Fenstern gelegt.

Aber eine innere Unruhe ließ es nicht zu. Mehr noch als nach Stille und Vergessen sehnte sie sich nach einem Beistand.

Langsam ging sie durch die Wohnstube. Bei den hohen Blattpflanzen, ihren gepflegten und geschonten Lieblingen, blieb sie einen Augenblick stehn. Sie las ein welkes Blatt ab und schaute nach den harten, knollenförmigen Knospen am Gummibaum.

Der Schreibtisch stand schön aufgeräumt. Neben den Schulheften lagen ein paar kleine dünne Bücher, -- Kindergeschichten, mit neuem Buchschmuck herausgegeben. Sie kosteten nur wenige Kopeken, und Marianne hatte sie voll Entzücken gekauft. Fast immer lag hier dergleichen, als warteten immer allerlei Kinderhände auf sie --.

So totenstill war es. Man war wie allein auf der Welt. Nichts von der hastigen Geschäftigkeit der Wochentage in der Wohnung.

Es wollte ihr vorkommen wie ein Atemanhalten um sie her. Alle Dinge wurden darin beredter, belauschbarer --.

Die Stille machte bange, sie war so selten allein.

Alle Dinge in dieser kleinen Wohnung liebte sie, ein jedes Stück darin hatte sie mit zärtlichem Bedacht gewählt, -- nur was sie lieb haben konnte, das hatte sie allmählich zusammengetragen.

Sie hatte gewünscht, diese Räume sollten mehr als wohnlich wirken, -- wie Arme, die sich weit und warm erschließen.

Aber sie wirkten nur so, weil geliebte Menschen sie erwärmten. Weil immer noch Sophie in ihnen ging und stand, lebte und lachte, -- weil Sophie in ihnen die Mutter erwartete, wenn sie abends müde von der Tagespflicht heimkam.

Wenn alle diese Liebesfülle keine Bethätigung mehr fand, dann konnte auch keine Liebe mehr auf die Dinge überströmen. Sie blieben nicht länger beseelt, -- sie entseelten sich, -- -- starben --.

Marianne fröstelte. Und plötzlich richtete sie sich entschlossen auf, schritt in den Vorflur hinaus und nahm ihren Mantel.

Sie wußte wohl, was sie thun mußte. Einen Beistand brauchte sie. Sie mußte, wie mit allem, so auch hiermit zu Tomasow. Mit ihm sich beraten, ihn hören. Daß er da war, das war eine Zuflucht.

Aber in all ihrem Verlangen danach fürchtete sie sich zugleich, und mit schwerer Hand machte sie sich fertig, zu ihm zu gehn. Sie wußte: zu den weichen Tröstern gehörte er nicht. Ihm eingestehn, was sie heute quälte, das hieß sich entscheiden --.

Draußen ruhte frostige Winterdämmerung, obschon es noch früh am Nachmittag war. Der Wind machte es bitterlich kalt. Marianne durchquerte einen Teil des Kreml; in dampfenden Wölkchen stieg ihr Atem und gefror zu Tausenden winziger Eisperlchen an ihrem Pelzkragen fest.

Stumpf und leblos wölbte sich der dicke Schnee um alles ringsum, rundete jeden Umriß, verwischte jede scharfe Linie. Hier und da klang ein Glockenton an, -- wie im Traum, -- leise verhallend. Es war, als raune eine Glocke der andern schlaftrunken etwas zu.

An manchen Kirchenthüren auf dem großen Kremlplatz lagerten Pilger oder lehnten an den Mauern, auf ihren Pilgerstab gestützt. Marianne war nicht in der Stimmung, um irgend etwas von der Außenwelt mit Interesse aufzufassen, aber auf diesem Bilde blieb ihr Blick mit einer dunkeln, unverstandenen Sehnsucht ruhen; über den zerlumpten Pilgern, -- über ihnen, die sich bis an die Thore der Gotteshäuser in vielleicht wochenlanger mühseliger Wanderung durchgefroren und durchgehungert hatten, lag eine solche kindliche Zufriedenheit. Man sah ihnen allen an, -- Greisen, Weibern, jungen Menschen: sie standen am Ziel -- da, wo sich alle Wünsche erfüllen, und man alle Bürden abwirft, -- _zu Hause_ --.

Gern hätte auch sie ihre Füße wund gelaufen, um Frieden zu finden und sich alles Schweren zu entlasten. Würde sie das erreichen, unter Tomasows klugen und guten Worten? würde sie es bei ihm erreichen? In diesem Augenblick glaubte sie es.

Bald war Marianne an seinem Haus angelangt. In einer ruhigen Straße stand es, einstöckig und unscheinbar, hinter einem hofartigen Vorgärtchen.

An den Vorflur stieß ein großes Schrankzimmer, wo der Diener, Andrian, sich aufzuhalten hatte, der, aus Tomasows Heimatsdorf gebürtig, ihm seit vielen Jahren anhing, und auch alle Reisen ins Ausland mitmachte. Dies Schrankzimmer erschien Marianne stets als der weitaus behaglichste Raum zwischen den konventionell eingerichteten Empfangsgemächern im Erdgeschoß. Vielleicht aus reiner Bequemlichkeit mochte Andrian hier alles zusammengehäuft haben, was seiner speziellen Pflege oblag: eine stattliche Reihe hoher Blattpflanzen, besonders mehrere prachtvolle Palmen, an denen er unermüdlich herumspritzte und putzte; daneben hing am Fenster ein Bauer mit einem singfrohen Kanarienvögelchen, Batjuschka »Väterchen« genannt, mit dem Andrian sich den ganzen Tag über alles, was geschah, unterhielt.

Marianne ertappte sich auf dem Gefühl, das manchen von Tomasows Patienten beschleichen mochte: lieber in diesem friedlichen Idyll von Palmenlaub und Vogelgezwitscher verweilen zu wollen, als sich weiter zu wagen in die Zimmer des Arztes.

Indessen noch hatte Andrian ihren Besuch nicht melden können, als bereits Tomasow selbst erschien, sichtlich beunruhigt über ihr unerwartetes Kommen. In Anwesenheit des Dieners that er keine Frage, sondern führte sie gleich durch seine Bibliothek in die Studierstube.

Marianne ließ sich in den ersten besten Sessel sinken, hilflos zu ihm aufschauend.

»-- Sophie will fort!« sagte sie unvermittelt, wie man mit geschlossnen Augen blind losschießt.

»-- Hat sie es Ihnen gestanden?«

Sie schüttelte den Kopf.

»Das nicht -- --. Aber untereinander werden beide gewiß schon davon geredet haben. So direkt sagt sie es nicht. -- -- Aber jetzt weiß ich: erst neulich brachen beide ganz verlegen ein Gespräch ab, weil ich unvermutet eintrat. Und ich -- meinte, es handle sich vielleicht nur um Weihnachten --. -- -- Haben die Mädchen am Ende auch Ihnen -- --?«

»Nein,« entgegnete Tomasow.

Er war vor ihr stehn geblieben, gespannte Aufmerksamkeit im Gesicht, während sie rasch und mit trockenen Lippen sprach.

»Nun, das ist gut,« fügte er jetzt hinzu.

»-- Gut --?!«

»Ja. Es mußte einmal zur Sprache kommen und zum Ausbruch, -- es war hohe Zeit!« sagte er ruhig, »denn vorher ließ sich nichts machen, weil Sie es nicht zuließen, Marianne. Obschon Sie es vor sich selbst verheimlicht haben, nagte die Furcht davor doch schon unablässig leise an Ihren Nerven. Das mißfiel mir längst. Aber nun ist es gut, daß es durchgekämpft wird.«

Marianne hob ihren Blick angstvoll zu ihm auf.

»-- Ich kann aber Sophie nicht hergeben! -- -- Nein, nicht auch Sophie noch -- --. Sie ist ja auch zart, sie bedarf meiner fortwährend -- -- Gott sei Lob und Dank, daß sie meiner noch bedarf!«

Tomasow zog einen Stuhl heran.

»Nun lassen Sie einmal sehen, Marianne! Jetzt bitte ohne alle Hinterhalte. Wie ist es denn mit Sophie? Sie machen doch ihrer Freude am Studium die weitgehendsten Konzessionen. Sie veranlaßten mich noch selbst, ihrem Verlangen nach ganz bestimmten Fachbüchern nachzugeben --«

»Ja,« sagte Marianne hastig, »so ist es ja auch. Weil doch ihr Interesse grade hierfür alle übrigen Interessen so entschieden überwuchs. Und wenn ich nun bedenke, daß Sophie die höhern Kurse besucht, und daß sie Sie zum Berater hat und vorwärts lernt, so viel sie nur will, -- ist es damit nicht genug? Muß sie durchaus auf den praktischen Arzt studieren, -- muß sie von mir fortgehn --?«

Tomasow zuckte scheinbar erstaunt die Achseln.

»Nein, selbstverständlich muß sie das keineswegs. Sie beruft sich dabei einfach auf ihr Reifezeugnis zum Universitätsbesuch und auf ihre Neigung, so zu handeln. Beides braucht ganz und gar nicht den Ausschlag zu geben. -- Indessen: ob ich sie für genügend befähigt dafür halte, ob mir die Sache aussichtsvoll erscheint, -- auch das haben Sie doch schon nebenher von mir zu erfahren gesucht, Ma.«

Marianne entgegnete heiser: »Ja, aber umsonst. -- -- -- Verstehn Sie denn nicht, Tomasow: ich wollte wissen, wie Sie sich selbst insgeheim dazu stellen, -- wie Sie selbst -- eventuell -- in meiner Lage handeln würden. Aber Sie antworteten stets nur auf ganz bestimmte praktische Fragen, eingehend und gewissenhaft. Dabei erfuhr ich das mir Wesentliche nicht.«

Tomasow erhob sich. Er antwortete zurückhaltend: »Nein, natürlich nicht. Denn abgesehen von den möglichen praktischen Ueberlegungen, gibt es da eben keine letzte, objektiv gültige Entscheidung. Was ich thäte, wenn ich Töchter hätte, kann ich nicht so abstrakt von vornherein feststellen, vielleicht -- möglicherweise -- wäre meine Erziehung der Ihrigen sogar entgegengesetzt von allem Anfang an. Vielleicht wäre sie weltlich, oder philiströs, oder gleichviel wie! Ganz genau aber kann ich feststellen, was _Sie_ thun werden, -- Ihrem ganzen Sein und Wesen nach, und das hätt ich Ihnen längst sagen können, wenn Sie es hätten hören wollen. Und offenbar, wenn ich nicht völlig irre, kamen Sie jetzt auch nur dazu hierher: nicht um meine Meinung zu erfahren, sondern um -- nun, um eine letzte kleine Feigheit zu überwinden, die Sie bisher noch hinderte, sich selbst anzuhören.«

Marianne sprang nervös auf.

»Wie reden Sie denn nur! Sie quälen mich!« murmelte sie gereizt, die Stimme voll Thränen.

Seine Augen richteten sich mit einem eindringlich forschenden Blick auf sie.

»Ich weiß, daß ich das thue!« sagte er ernst. »Und ich weiß auch, daß Ihre Nerven grade heute um Schonung schreien. -- Und nun hören Sie mich an, Marianne, und zwar ganz getrost, denn ich kann Ihnen wirklich helfen, wenn Sie nur wollen. Ich schlage vor: überlassen Sie die ganze Sache mir. Ueberlassen Sie es mir, Sophie von ihren hochfliegenden Wünschen zu kurieren. So gänzlich zu kurieren, daß sie nie wieder Lust nach dem ärztlichen Studium und Beruf verspürt. Wollen Sie?«

Marianne sah ihm ungläubig in die Augen.

»Wie sollte das wohl möglich sein? Womit könnten selbst Sie das erreichen?«

»Das ist meine Sache. Für das Gelingen steh ich ein.«

Ein seliger Hoffnungsschimmer überflog ihr Gesicht, aber so zaghaft noch, daß es ihn rührte.

»Aber -- warum hätten Sie das dann nicht längst gethan?!«

»Warum? Nun offenbar darum, weil Sie ja für die Pläne und Interessen Ihrer Kinder nicht nur Nachsicht zeigen, sondern sie gradezu -- in Ihrer unnachahmlichen Art, Ma, -- heilig halten, ängstlich bemüht um die geistige Eigenart jedes einzelnen.«

Marianne sah sehr unruhig aus.

»Ja, das ist doch aber auch das einzig Richtige? -- Sie sprechen ja jetzt doch wohl nur davon, Sophie rechtzeitig in wirklich bestehende und unausweichliche Schattenseiten Ihres Berufes einzuweihen --?«

Tomasow schwieg einen Augenblick.

»Meine liebe Ma!« versetzte er dann. »Die Dinge sind nun einmal, als was sie uns erscheinen. Suggestion ist schließlich alles. Ich halte mich für sehr wohl im stande, stärkern Wesen als ein Mädelchen wie Sophie ihr Studium für alle Ewigkeit hinaus zu verekeln, unerträglich zu machen, -- und ebenso bürge ich dafür, daß ich ein viel zarteres kleines Menschenkind, als sie ist, mit etwas Kraftaufwand durch alle Schwierigkeiten und Fährlichkeiten derselben Sache mit Erfolg hindurchbringen würde.«

Marianne machte eine hilflose Bewegung. Sie suchte nach Worten, -- lehnte sich innerlich auf gegen die Worte, die ihr kamen, -- und endlich entschlüpfte es ihr leidenschaftlich: »-- Nein -- o nicht! Sophie nichts anthun! Nichts Hemmendes, nichts Arges --. Nichts gegen ihr Wachstum, nichts gegen ihre Kraft und Freudigkeit --,« sie unterbrach sich und hielt erschrocken inne.

»... nichts gegen ihren Wunsch, fortzugehn --?« ergänzte Tomasow.

»Also doch!« murmelte er, als sie darauf nichts antwortete.

Er nahm ihre Hand in die seine, küßte sie fast unwillkürlich und hielt sie fest, während er sich dicht über Marianne neigte: »Kind! Jetzt haben Sie sich richtig selbst in die Entscheidung hineingestoßen, -- jetzt besiegen Sie auch die Angst, die Sie haben, weiter zu sprechen. Sehen Sie nun ein, wie wenig es hilft, Ihnen helfen zu wollen? Sie laufen ja doch gradeswegs in das hinein, was Ihnen das Schwerste ist und Sie ängstigt. Und eben deshalb muß es entschieden sein! Dieser hingezogene Kampf ist ein Wahnsinn. Verwerfen Sie meinen Vorschlag von vorhin, so siegt Sophie. Soll sie das --? Soll sie gehn dürfen, oder soll sie bei Ihnen bleiben --?«

»-- Gehn!« sagte sie und brach in ein bitterliches Weinen aus.

Tomasow ließ sie mehrere Minuten gewähren.

Er atmete tief auf und ging einigemal im Zimmer auf und ab. Sein Gesicht behielt dabei den gespannten, aufmerksamen Ausdruck.

Dann kam er wieder zu Marianne. Er zog ihr leise, mit sanftem Zwange die Hand von den Augen, die sie verdeckt hielt.

»Nun ist es aber genug!« äußerte er lächelnd, »zeigen Sie Ihren Nerven den Herrn. -- Wollen Sie nicht eine Tasse Thee nehmen? Sehen Sie, dort steht das ganze Geschirr noch, -- ich war grade dabei, als Sie kamen. Zur Strafe trinken Sie ihn nun kalt, natürlich.«

Sie gehorchte mechanisch und ließ sich ein wenig Thee eingießen, in den Tomasow aus einem Arzneifläschchen ein paar Tropfen mengte.

Dann überließ er sie wieder sich selbst und nahm den Spaziergang im Zimmer von neuem auf.

Aber Marianne erhob sich vom Eisbärfell.

»Es ist spät geworden. Ich will nach Hause gehen,« sagte sie mit einer leisen Stimme, »die Kinder sind gewiß schon zurück und warten erstaunt. Sie waren nur für kurze Zeit mit Wera Petrowna ausgegangen.«

Tomasow blickte auf die Uhr.

»Wie Sie wollen, Ma. Vielleicht ist es so am besten. Indessen -- sind Sie jetzt auch schon dazu im stande? Sind Sie Ihrer selbst ganz sicher? Ich lasse Sie nicht fort, ehe ich das genau weiß.«

Und als Marianne ihn müde fragend ansah, fügte er hinzu: »Ihrer Töchter halber ist es notwendig, daß sie ihre Mutter in dieser Angelegenheit fest und sicher auftreten sehen. Als eine Autorität -- nicht wie ein hingeschlachtetes Opferlamm. -- Darum müssen Sie es sein, Marianne, die entschlossen die Initiative ergreift.«

»-- Ich soll selbst --?« murmelte Marianne.

»Ja. Das ist notwendig, und zwar sofort. Lassen Sie die Ungewißheit keine Stunde länger anstehen. Lassen Sie sich keinen Raum zu Beängstigungen und Traurigkeiten dazwischen. Bringen Sie noch heute -- heute noch! die Sache zur Sprache und Entscheidung.«

»-- Heute?!« wiederholte sie erschreckt.

Sie war tief erblaßt.

Tomasow ergriff ihre Hand und nahm sie in seine beiden Hände. Er sagte ermutigend: »Versuchen Sie es nur! Bleiben Sie nicht mitten im Kampf stecken, der Ihren Nerven stündlich härter zusetzen wird -- überstehen Sie es schnell ganz. Hinterher kommt die allheilende Ruhe. -- Glauben Sie, daß Sie es mir versprechen können?«

»Ja. Ich will es thun,« sagte sie traurig.

»Dann lasse ich Sie ruhigen Herzens fort. -- Wenn Sie erlauben, geleite ich Sie selbst an einen Schlitten,« bemerkte Tomasow und führte Marianne durch die Bibliothek hinaus.

Er schellte nicht dem Diener, sondern gab ihr selbst den Mantel um. Marianne that seine Art so wohl, wie einem leise umsorgten Kinde.

»Ich bin ganz zerschlagen und wund,« meinte sie mit einem mühsamen Lächeln, »aber ich danke Ihnen, Tomasow.«

»Ach, Ma --« er stockte und murmelte: »Wenn Sie nur -- wenn Sie wenigstens ohne Groll herdenken. Es ist eine schändliche Aufgabe, die mir wiederholt zufällt, Ihnen weh thun zu müssen, Sie zu etwas Hartem ermannen zu müssen. -- Die Erleichterung wird auch diesmal nachkommen, ich hoffe es mit Bestimmtheit. Aber die Ueberwindung ist deshalb nicht minder schwer.«

Marianne schwieg. Sie stand, fest an ihn gelehnt und schloß die Augen.

Nein, so feige würde sie doch nie sein, sich nicht immer diesem unbestechlichsten aller Freunde mit ihren Nöten und Schwächen anzuvertrauen, weil er streng gegen sie war! Ein großer Dank gegen ihn stieg in ihr auf. Wenn nur er ihr blieb --!

Tomasow verstand die stumme Antwort vollkommen.

Er öffnete die Thür und rief Andrian zu, einen Schlitten vor das Gitterthor zu winken.

Dann geleitete er Marianne durch den verschneiten Vorgarten, half ihr einsteigen und knüpfte ihr die Felldecke um die Kniee.

»Ich bin heute viel aus,« bemerkte er dabei, -- »darf ich gegen Abend für einen einzigen Augenblick bei Ihnen vorsprechen? Mich überzeugen, wie alles steht --?«

Marianne nickte. Sie wußte, wovon er sich überzeugen wollte --. Dann also mußte es schon geschehen sein --. Ihr schlug das Herz stärker bei dem Gedanken.

Als der Schlitten fortfuhr, ging Tomasow langsam ins Haus zurück.

Andrians Gesicht strahlte, er freute sich immer, wenn er Marianne sah, denn es kam vor, daß sie sich von ihm Geschichten aus dem Dorfleben erzählen ließ, und das war ihm das Höchste. So erfuhr sie manche Einzelheit aus Tomasows Kindheit, der als kleiner Bursche, zu Besuch beim Großvater, -- einem echten alten Bauern, -- mit Andrian noch barfuß umhergelaufen war.

»So ein Mütterchen, -- wirklich, so ein prächtiges!« entschied Andrian, und sah seinen Herrn lächelnd an, während er seine schwachen kurzsichtigen Augen zukniff, die der Schnee blendete. Ganz wie sein Herr trug er einen Kneifer, wenn auch keinen goldnen, und nur einen mit dunkelm Schutzglas. Er fühlte sich sehr stolz auf diesen Kneifer, und kam sich darin ganz wie ein Ausländer vor.

Tomasow würdigte Andrian keiner Antwort. Er ging schweigend in sein Zimmer hinüber und ließ den Thee forträumen.

Nachdenklich schritt er dabei auf und ab.

»So ein Mütterchen!« In seinen eignen Erinnerungen spielte Elterntreue eine große Rolle. Den Vater hatte er wenig gesehen: der hatte sich zum Kaufmann und Reeder heraufgearbeitet, ungeheuer erwerbstüchtig, ungeheuer strebsam, bewußt einseitig, ohne Zeit sich Bildung anzueignen: alles das für die Kinder. Die sollten dann alles haben: Bildung, Macht, Geld, Glück. Zwei Schwestern von Tomasow verheirateten sich früh und ansehnlich. Und er, als Student der Medizin, in jugendlichem Enthusiasmus fast in nihilistische Umtriebe verwickelt, voll drängender, unruhiger Energie, kam immer wieder ins Dorf zurück, zum Großvater. Wenn er den Alten vor sich sah, eisgrau, mit den klugen, beredten Augen unter den buschigen Brauen, dann erschien er ihm in seinem Schafspelz wie ein ganz Großer, wie ein Fürst oder Gewaltherr. Herr in seiner Hütte, auf seinem Felde, Ahnherr eines starken Geschlechts. Dies Dorfbild behielt für Tomasow eine sonderbare Poesie --.

Plötzlich blieb er mitten im Hin- und Herschreiten stehn. Er horchte. Drüben im Dienerzimmer unterhielt sich Andrian mit Batjuschka. Er pfiff ihm russische Weisen vor und erzählte --.

Tomasow beschlich ein leiser Neid. Wenn Andrian seinen Kneifer fallen ließ, so war er wieder der Bauer von einst, aller europäische Firniß fiel einfach von ihm ab. Wer das ebenso machen könnte, oder aber sich eine neue Welt bauen --. Ja, der wäre erst des »Mütterchens« wert --.

Er stand auf und horchte auf das Geplauder und Gezwitscher in der Dienerstube.

* * * * *

Ma erwartete zu Hause eine Ueberraschung.

Ihre beiden Mädchen waren soeben heimgekommen. Noch stand die Wohnungsthür weit offen, und ein Bauersmann mühte sich eben damit ab, einen hohen herrlichen Weihnachtsbaum in der Stube unterzubringen.

Sophie sah die Mutter glückstrahlend an. Es war doch eine gute Idee, das mit dem Baum! Es war _ihre_ Idee. Ma hatte ihn sich doch so sehr gewünscht, und wenn sie ihr auch erst gestern abend etwas weit Großartigeres darbringen wollte, so erleichterte sie dies doch für den Augenblick.

Cita stand noch in Mütze und Pelzjacke und lohnte den Mann ab; mitten im Wohnzimmer erhob sich jetzt die Tanne und duftete wirklich wie ein ganzer Wald. Oben stieß sie sogar ein wenig an die geweißte Decke an, sodaß sie ihre höchste Spitze krümmen mußte, von der Seite jedoch breitete sie ihre Aeste ebenmäßig und tiefgrün, wie ein schirmendes Dach, über Mas Schreibtisch aus.

Sophie hatte sich an das geöffnete Pianino gestellt, das der Baum von der andern Seite überschattete, und unter seine Zweige gebückt, suchte sie ein paar Accorde eines alten Weihnachtsliedes.

Die Mutter äußerte nichts, bis der Mann hinausgegangen war. Sie sah blaß aus, und ihre Augen besaßen etwas so Stilles, so nach innen Gekehrtes im Blick.

Endlich sagte sie mit ihrer warmen Stimme: »Dank euch! Ja, dies Weihnachtsfest soll uns schön werden, wie nie eins gewesen ist! Wir wollen froh sein, wir drei zusammen! Denn es wird hier am Ort unser letztes sein. Uebers Jahr feiert auch Sophie es nicht mehr hier. -- Ich dank euch, ihr Kinder.«

Sophie, die eine leise Melodie angeschlagen hatte, brach mit einem gräßlichen Mißton ab.

Cita, eben im Begriff, ihre Sachen abzulegen, hielt erwartungsvoll inne und blickte die Mutter an.

Da ging Marianne zu ihrer Jüngsten hin und nahm sie in die Arme.

»Aber nicht getrennt!« sagte sie bewegt, »-- ich werde mein Weihnachtsfest da haben, wo du grade studieren wirst.«

»-- Ach -- Ma!« schrie Sophie auf.

Sie glaubte es noch nicht recht. Mit dunkel gerötetem Gesicht schaute sie angstvoll und zugleich strahlend zur Mutter auf und umklammerte ihren Hals.

»-- Ach, Ma --! Ist es denn wirklich wahr --?«

Dieser Augenblick that Marianne doch bitterer weh, als sie jetzt eben beim Heimkehren geglaubt hatte. Sie drückte Sophiens leuchtendes Gesicht an sich, um nicht den Ausdruck der Freude darin zu sehen.

»Ja, es ist wahr, Herzenskind. Alles Nähere besprechen wir noch ein anderes Mal. Auch mit Cita muß ich noch vieles besprechen. So ganz einfach ist es nicht. -- Aber die Sache selbst ist entschieden. Nun sollst also auch du hinaus, -- gebe Gott, einst zu deinem und deiner Mitmenschen Segen.«

Sophie drückte sich fester an sie.

Sie schämte sich schrecklich vor Cita, aber sie weinte dennoch Ströme von Thränen in Mas Hals hinein, als ob sie nichts in der Welt je von da fortreißen sollte --.

Cita stand mit großen ernsten Augen beiseite. Das Wort, das ihr innerlich kam, lautete ganz spontan: »Donnerwetter!« Aber glücklicherweise behielt sie es bei sich.

Ein tiefer Respekt prägte sich auf ihrem jungen Gesicht aus.

Plötzlich kam sie auf die Mutter zu, ergriff deren Hand und küßte sie.

»Du bist wahrhaftig der famoseste Kerl unter der Sonne, du herrliche Ma!« versicherte sie ganz begeistert.

Marianne lächelte nicht über diese Ehrfurchtsbezeugung; sie überlegte auch nicht, ob sie nun nicht gradezu glänzend ihre Autorität behauptet und die Initiative ergriffen habe.

Sie hielt ihr weinendes Kind im Arm und bückte ihr Gesicht tief zu ihm herab, als lausche sie fast gierig diesen Thränen, -- als redeten diese Thränen artikuliert zu ihr -- Süßes, Versöhnendes, Beschwichtigendes --.

Dann trocknete sie Sophie, wie einem kleinen Kinde, das nasse Gesicht mit ihrem eignen Taschentuch ab.

»Komm,« sagte sie sanft, »es ist doch ein großer Entschluß und daher ein großer Tag für dich. Geh hinaus und bring uns eine Flasche Wein. Wir wollen auf dein Wohl anstoßen.«

Sophie ging, der Mutter Taschentuch vor die Augen gepreßt, langsam, als sei dieser Tag mehr ein schwerer als ein großer für sie.

Cita sah ihr unwillig nach.

Sie bemerkte zur Mutter: »Sophie ist doch noch sehr ein Kind. Hiernach muß doch nun ein jeder denken, es ginge zur Schlachtbank. Aber du kannst mir glauben, daß sie darauf brennt, zu studieren. Man muß nur erst in ihr alles das klären und ordnen.«

Marianne schwieg einen Augenblick.

»-- Bist du es, die diesen Entschluß in ihr zu klären versucht hat?« fragte sie dann ruhig.

Cita begegnete ihrem Blick fest und offen.

»Ja, Ma. Sobald mir das selbst klar geworden war. Sie konnte nur nicht den Mut finden, dich zu fragen --. Sieh, ich stehe ja so dazu: es ist etwas, wofür ich jederzeit kämpfe und eintrete, -- wie denn also nicht, wo es die eigne Schwester gilt? Nur mit einem Unterschiede freilich: daß ich in diesem Fall nicht nur für die allgemeine Sache einstehe, sondern auch mit jedem Blutstropfen für Sophie selbst. Daß ich mich ihrem Leben verbinde, ihr helfen, zu ihr halten will jederzeit, -- was auch geschehe.«

Marianne zauderte nur noch einen letzten Augenblick. Dann reichte sie ihrer Aeltesten schweigend die Hand.

Sie schauten einander dabei voll in die Augen, wie zwei Freunde, die, wenn sie auch nicht auf ganz gleichem Boden kämpfen, es doch in gleichem Sinn und für dasselbe höchste Ziel thun.

»Ich stelle Sophie in deine Obhut, -- ich baue auf deine Treue: Höheres hab ich dir nicht anzuvertrauen,« sprach Marianne leise; »-- Sophie war ›sein‹ Liebling -- und ›seinen‹ Blick hat Sophie. Mir ist, als ginge noch einmal ›er‹ von mir hinweg, indem sie geht --.«

Cita war sehr blaß.

Ihre Schwester kam mit Rheinwein und Gläsern zurück, entkorkte die Flasche und goß ein.

Keiner von den dreien sprach ein Wort, als Marianne ihr Glas erhob und mit ihnen anstieß.

Sie küßte ihre blonde Tochter, ihr zarteres Herzenskind, doch that sie es heiter und herzhaft, um keinesfalls mehr Thränen aufkommen zu lassen.

Cita unterstützte sie in dieser Absicht nach Möglichkeit, denn es verletzte sie fast, daß Sophie heute weinen konnte.

»Eigentlich ist das ja ein Weihnachtsgeschenk, das allergrößte, und gleich unter den noch ungeschmückten Baum gelegt!« sagte sie scherzend, »-- wie kann man nur seine Gaben so vorweg verschwenden, Ma! Jetzt sollte ich von Rechts wegen alle übrigen Geschenke bekommen, denn Sophie hat nun an diesem einen vollauf genug.«

»Bis zum Weihnachtsabend hab ich vielleicht noch ein andres Geschenk für euch, -- und dann für euch beide!« erwiderte Marianne mit leisem Lächeln, und man hörte ihr an, daß sie von einer noch zaghaften, aber goldnen Hoffnung sprach.

»Noch ein andres? Noch ein schöneres? Nein, denn das gibt es ja gar nicht mehr auf der Welt. Nicht wahr, Sophie?«

Sophie schüttelte energisch den Kopf, ihre geröteten Augen strahlten jetzt doch.

»Also dies einzig ist das Schönste für sie, Besseres gibt es nicht!« dachte Marianne still, einen Augenblick lang weh berührt, doch an der verschwiegnen Hoffnung, die sie hegte, hob sich ihr Mut wieder. Diese Stunde sollte eine freudige sein, und sie wurde es. So vieles drängte sich zur Aussprache, den beiden Mädchen wurde es in diesen Minuten erst bewußt, daß sie in mancherlei Heimlichkeiten gelebt hätten die Zeit über, -- und daß es köstlich sei und an sich schon ein Fest, keinerlei Heimlichkeiten mehr zu kennen, Mas Blick und Lächeln gegenüber.

Und allgemach lenkte Marianne das Gespräch in immer ruhigere Bahnen. Sie saßen eng zusammengerückt bei der halbgeleerten Flasche, und während sie die praktische Seite der Frage näher erörterten, scherzten sie schon wieder.

Endlich stand Marianne auf. Es war fast halb sechs geworden.

»Jetzt möchte ich hineingehn und ein wenig ruhen, ihr beiden Taugenichtse. Diese Nacht war nicht gut für mich. Und morgen ist kein Sonntag mehr --. Aber von da an nehmen die Stunden endlich reißend ab. -- Bis wir um halb sieben essen, bin ich wieder da. Sollte nun noch inzwischen ein Sonntagsgast kommen, so bestrickt ihn mit so viel Liebenswürdigkeit, als ihr wollt, mich jedoch soll er auf alle Fälle in Frieden lassen.«

An der Thür wendete sie sich noch einmal nach den Mädchen um und nickte ihnen zu. Sie sah ihre leuchtenden zutraulichen Augen, und ein warmes Dankgefühl kam über sie, als fiele langsam von ihren Schultern eine Last, unter der gebückt sie gegangen war: -- wieder lagen jetzt die Herzen ihrer Kinder offen und ihr zu eigen vor ihr da, wie ihre blühenden Gärten. --

Nur ein Sonntagsgast schellte ein wenig später. Es war Tomasow.

Marianne hatte gewußt, daß er noch kurz vorsprechen wollte, indessen hatte sie selbst ihn in diesen Stunden vollständig vergessen.

Die beiden Mädchen erzählten ihm wörtlich den Auftrag der Mutter, falls jemand zu Besuch käme. Er mußte lachen --, nun wußte er genug.

Was etwa noch fehlte, ergänzte ihm ein einziger Blick auf die Schwestern. Sophies Gesicht war noch voll roter Thränenspuren. Cita war blaß und die dunkeln Augen brannten ihr.

»Nun, das hier scheint mir ja schon mehr ein Bacchanal gewesen zu sein!« bemerkte Tomasow, als er ins Wohnzimmer kam, wo noch die leeren Gläser standen.

Sophie fuhr es heraus: »Ja --! Denn ich soll nun Cita ins Ausland folgen und von Ostern ab Medizin studieren!«

Sie kam aus der Küche, die weiße Schürze schief umgebunden; heute konnte man wohl einige Bedenken wegen ihrer Beaufsichtigung des Mittagmahles hegen.

Tomasow sprach das nicht aus; er sagte nur: »-- So, so. -- Nun, und Ma, -- was sagt denn die dazu?«

»Ma ist es ja grade, die es selbst vorgeschlagen hat,« erklärte Cita.

»So. -- Nun, und wo wird denn Sophie diese große That thun?«

Sophie rief: »Aber natürlich in Berlin!«

»Natürlich da, wo ich mit ihr zusammen sein kann,« meinte Cita.

»Nein, Cita, das kannst du so doch nicht sagen. Deshalb allein doch wohl nicht,« verbesserte Sophie einschränkend.

Tomasow hatte sich im Schaukelstuhl niedergelassen.

Er nahm seinen Kneifer aus der Seitentasche, rieb ihn mit einer Ecke des bastseidenen Taschentuches klar und setzte ihn auf seine etwas stumpfe Nase. Dann blickte er den beiden sichtlich noch ganz aufgeregten Mädchen nacheinander prüfend ins Gesicht.

»Eine kleinere Universitätsstadt, -- eine solche natürlich mit gut bestellter medizinischer Fakultät, -- wäre für den Beginn ebenfalls nicht übel!« bemerkte er langsam.

»Ach nein!« rief Sophie unwillig und ergriff ihn am Aermel, »-- daß Sie sich nicht etwa unterstehn, Doktor Tomasow, unsrer Ma dergleichen einzublasen!«

»Aber Sophie, du benimmst dich rein wie ein Kind!« tadelte Cita, von der zwanglosen Intimität dieser Worte unangenehm berührt.

»Mir scheint hiernach aber doch,« nahm Tomasow sehr gelassen das Wort, »daß Sophie nur mit löblicher Offenherzigkeit ihres Herzens Meinung, -- und auch Ihres Herzens Meinung, Cita! -- kundgibt. Mir scheint, daß bei Ihnen die Wahl des Ortes fast eine ebenso wichtige Rolle spielt wie die soeben erst eingeholte Erlaubnis zum Studium selbst, -- hab ich nicht recht?«

Sophie errötete und wollte widersprechen. Aber Cita setzte sich Tomasow gegenüber seitwärts auf einen Stuhl, schlang den Arm um die Lehne und bemerkte eifrig: »So kindisch ist es nicht zu nehmen, wie es bei Sophie leicht aussieht. Allerdings freut sie sich darauf, -- und ich für sie! -- daß sie auch außerhalb des Studiums am Leben teilnehmen wird. Aber selbstverständlich nicht etwa an seichten Vergnügungen! Nicht um irgend welcher Genüsse willen, die eine große Stadt naturgemäß reicher bietet, --.« Citas Lippen kräuselten sich bei dieser Erwähnung fast so verächtlich, wie die einer jungen Nonne, die im Kloster vom Weltverzicht spricht.

Im »Spalt« nebenan, wohin Sophie eben verschwunden war, um einiges Geschirr für die Küche zurechtzustellen, hörte man es beängstigend laut klirren.

»-- Sondern --?« forderte Tomasow Cita zum Weitersprechen auf. Der Kneifer saß ihm noch immer auf der Nase. Eigentlich hatte sie wenig Lust, weiterzusprechen. Sie fand ihn heute ganz merkwürdig arrogant aussehend.

»-- Sondern um teilzunehmen am Leben der heutigen strebenden Frauenwelt, -- an dieser ganzen Bewegung,« sagte sie dennoch. »Sophie wird sich bald, so wie ich es thue, innerlich eins damit fühlen, daran emporwachsen --«

»-- Jedenfalls hat es etwas Begeisterndes!« fiel Sophie ein, die es doch nicht aushielt, im Hintergrunde zu bleiben. Sie hatte das Geschirr niedergesetzt und trat wieder zu ihnen. Sie fand, daß man ganz über sie hinwegspräche, während es sich doch ausschließlich um ihre eigenste Angelegenheit handelte. Auch sie wollte sich Luft machen und mit ihrer Ueberzeugung herausrücken.

So fuhr sie lebhaft fort: »Es ist doch etwas ganz andres, ob man so vor sich hin studiert und nur ganz egoistisch an die eigne Zukunft denkt, -- oder ob man mit allen zusammen diesen neuen großen Zielen entgegengeht. -- -- Es hat etwas Begeisterndes!« wiederholte sie mit einer inbrünstigen Betonung, die darüber hinweghelfen sollte, daß ihr gar nichts weiter einfiel.

Sie stand neben Tomasows Stuhl, sodaß er zu ihr hinaufsehen mußte. Wie sie diese Worte mit so viel Wärme sprach und dabei so zart und lieblich dastand, flog ein Ausdruck durch seine Augen, der Cita frappierte, obwohl sie ihn nicht verstand. Arrogant nahm er sich jedenfalls nicht mehr aus.

Tomasow nickte vor sich hin und bemerkte, indem er den Kneifer fallen ließ: »Ja ja, es ist schon so. Studieren oder nicht, -- das ist gar nicht mehr allein die Frage. Sondern damit bildet sich zugleich ein neuer Typus der Frauen heraus, -- ja, gewissermaßen ein neuer Typus, man muß es wohl so nennen. Damit, daß eine studiert hat, ist es nicht mehr abgethan.«

»Sehr richtig! Man muß das nur erst allerseits einsehen lernen!« bestätigte Cita billigend, während ihre Schwester mit einem unterdrückten Seufzer in die Küche abging, obwohl sie sich weit lieber an dieser interessanten Diskussion beteiligt hätte.

»Sind Sie nun eigentlich für oder gegen den neuen Typus -- so im Grunde Ihrer Seele, Doktor Tomasow? Farbe bekennen!« fügte Cita lächelnd hinzu.

Jetzt waren seine Augen wieder voller Spott.

Er verneigte sich, das Lächeln zurückgebend, ironisch vor dem jungen Mädchen.

»Werde die Ehre haben, mich zu entscheiden, sobald Sie mir das erste vollzählige Regiment neuer Musterexemplare vorführen! -- -- Einstweilen, -- Sie wissen: wer neue Wege sucht, muß sich drauf gefaßt machen, unter Umständen mit zerfetzten Kleidern und einigen dicken Beulen und Schrammen aus dem Dickicht wieder aufzutauchen, -- -- was einem Frauengesicht --«

»-- Davor fürchten wir uns nicht, Doktor Tomasow!« unterbrach ihn Cita etwas scharf, einen feinen Hochmut um die Lippen.

»Nein, -- wie ich sehe!« versetzte er, und wieder glitt der Ausdruck von vorhin durch seine Augen, »-- auch befürchte ich selbst für euch beide jetzt noch kaum sehr viel. Nein, für euch beide minder als für manche andre. Denn möglicherweise seid ihr bis zu gewissem Grade -- gefeit. -- Obschon keinesfalls durch euer eignes Verdienst,« fügte Tomasow hinzu, indem er sich aus dem Schaukelstuhl erhob. »Ich muß nun gehn. Meinen Gruß eurer Mutter und der kleinen zukünftigen Kollegin.«

»Gefeit, und nicht durch eignes Verdienst?!« wiederholte Cita erstaunt und entrüstet. Auch sie stand auf und trat mit ihm hinaus auf den Vorflur; »-- das wäre wirklich das Aeußerste. Wenn wir einmal durch eigne Kraft etwas Tüchtiges geworden sind, werden Sie uns auch noch das Verdienst daran abstreiten --! Ich möchte wissen, wer dies Verdienst -- --«

Sie vollendete nicht, weil sich grade die Thür zu Mariannens Schlafzimmer öffnete, und diese in den Gang hinaustrat, wo ihr Sophie von der Küche her entgegenlief.

»Das Essen ist gleich fertig!« rief Sophie erhitzt.

Marianne kam auf den Gast zu.

Tomasow, der schon im Pelz, zum Fortgehn bereit, dastand, blickte Cita schweigend an.

Und plötzlich verstand sie, was er meinte, -- wen er meinte --. Ihre Entrüstung hielt nicht stand, fast gegen ihren Willen kam Demut in ihre Augen, als sie dem Ehrfurchtheischenden in seinen Augen begegnete. Denn dieser Blick hatte fast etwas Gebieterisches, etwas, was sich ihr eindrücken, einprägen wollte, wie eine Stimme, die deutlich sprach: »Ihr seid die Kleinen, die eine Große großmütig auf ihre Schultern hebt. Eine, die ihre Schultern beugt, damit sie euch tragen kann. Ich weiß das: ich habe geholfen, euch da hinaufzuheben. Nun seht ihr euch die Welt von da oben an!«

»Was, Sie wollen schon gehn?!« fragte Marianne und gab ihm die Hand.

»Ja, ich muß gehn. Und Sie, lassen Sie gefälligst die Suppe auf dem Tisch nicht kalt werden, -- nach meiner Berechnung hat sie heute dem jüngsten Fräulein Tochter arge Mühe gekostet. -- -- Froh bin ich, Sie noch zu sehen. Sie sind aber auch eine entsetzliche Langschläferin, meine Gnädige.«

»Ja, ich habe wirklich geschlafen!« sagte Marianne.

Sie stand lächelnd, mit schlafroten Wangen, wie ein eben aufgewachtes Kind, und mit blinzelnden Augen da, denen das Lampenlicht noch weh that.

An jeder Seite hing ihr jetzt eine Tochter. Sophie hatte ihr einen Arm um die Hüfte geschlungen und sich an sie geschmiegt, sodaß sie nicht vorwärts gehn konnte. Cita schob ihre Hand leise in den Arm der Mutter.

Marianne stand da und strahlte in einer so warmen und innigen Schönheit, daß Tomasow ganz betroffen davon war.

»-- Sie ist ja doch die tausendmal Jüngste von allen dreien, -- die tausendmal Anfänglichere --; sie ist wie das Leben an der Wurzel selbst und am unversieglichen Anfang --!« dachte er wie berauscht, als er die Treppe hinabstieg.

Ganz langsam trat er den Heimweg an.

Ein eigenartiges Triumphgefühl mischte sich in sein Entzücken über Marianne, -- eine feine Sensation, wie sie ihm nur durch ihr Wesen vermittelt wurde. Das kam von dem ausschlaggebenden Anteil, den seine Bestimmungen an allen ihren wichtigen Entschlüssen zu haben pflegten. Was sie so schön und sieghaft aussehen ließ, führte stets irgendwo auf einen Einfluß, ein Zureden, einen Rat von ihm zurück: und bei ihrer ganzen Art, so tief und inbrünstig zu leben, lag in dieser Mitarbeit daran etwas, was seinen Ehrgeiz wunderlich erregte.

Mochte er auch in seinem persönlichen Dasein enttäuscht oder gleichgültig geworden sein in hundert Punkten, -- in diesem einen Punkt fühlte er um viele Jahre jünger, in diesem einen Punkt bekam seine Energie wertvollen Spielraum und großen Stil.

Als sich Tomasow schon seinem Hause näherte, blieb er zögernd stehn. Er bog in eine hügelige Seitenstraße und schritt sie langsam hinauf, bis ihm die kleinen erhellten Fenster des Stifts für unbemittelte Frauen entgegenblinkten.

An den Zaun gelehnt, schaute er nach dem Erdgeschoß hinüber, dann trat er an das Mittelgebäude heran und klopfte mit seinem Stock leicht an das Fenster von Wera Petrownas Stube, wo kein Licht brannte.

Das Klopfen wurde sofort von innen erwidert, und als er dann durch den Hausflur ging, wurde auch schon die Zimmerthür geöffnet.

Wera Petrowna war eifrig damit beschäftigt, die Lampe anzuzünden, sie sagte vor aller Begrüßung, indem sie eilig ein Streichholz anstrich, abwehrend: »-- Ja, ich weiß, -- ich weiß schon: ich soll nicht abends im Dunkeln dasitzen, um den Tropfen Petroleum zu sparen, und vorzeitig einzunicken auf dem alten Sofa, und dann nachts nicht zu schlafen --. -- -- Aber ich bin wirklich eben erst nach Hause gekommen, -- und, der Abwechslung halber, -- -- es denkt sich so gut im Dunkeln.«

Sie setzte die Glaskuppel auf die Lampe, deren schwerer Fuß und vorzügliches Brennwerk aus bessern Zeiten stammten, und schob sie in die Mitte des Tisches vor das geblümte Sofa.

»Unverbesserlich!« bemerkte Tomasow.

»Herrlich, daß Sie mal kommen! Seit einer Woche freu ich mich schon von Tag zu Tag, --« lenkte sie ab und ging geschäftig zu der Kommode, wo das Schachbrett nebst Figurenkasten immer bereit stand.

Sie griff nach dem Brett und schaute Tomasow fragend und bittend an.

»-- Sie mögen doch --?«

Er nahm ihr Brett und Kasten ab, trug beides auf den Tisch und rückte einen Stuhl heran.

Aber anstatt die Figuren aufzustellen, setzte er sich nur hin, stützte den Kopf in die Hand und blickte zerstreut in das geöffnete Kästchen, als müsse er raten, was darin sei.

Wera Petrowna hatte sich ihm gegenüber auf das Sofa niedergelassen und sah erwartungsvoll zu. Als nichts weiter kam, schüttelte sie den Kopf.

»Schlechter Laune!« konstatierte sie erbarmungslos.

Dabei schob sie ihm aufmunternd die Zigarettenschachtel hin. Die Zigaretten ihres Neffen waren gar nicht zu verachten.

»Von wo kommen Sie denn? Hat vielleicht irgend ein Patient Ihnen den Kopf beschwert?«

»Nein. Ich komme jetzt eben von Frau Marianne.«

»Ach so -- --, am Ende -- -- selbst Patient --?«

Tomasow schaute zu ihr hinüber und runzelte merklich die Stirn.

Die Alte setzte ihr allerharmlosestes Gesicht auf.

»Nun, nichts für ungut. Mit bejahrten schwatzhaften Personen muß man Nachsicht üben, lieber Tomasow. -- -- Und wir Frauen sind nun mal so veranlagt, daß es uns immer nur von der Liebe zu singen und zu sagen drängt.«

Er mußte unwillkürlich lächeln, Wera Petrownas Worte und ihr Aeußeres bildeten einen zu heitern Kontrast. Mit ihrem alten energischen Gesicht und im fadenscheinigen weiten schwarzen Gewande, -- dem ziemlich traurigen Produkt eigner Schneiderkunst, -- in dem sie zu Hause umherging wie in einem Talar, sah sie einem herabgekommenen russischen Popen um vieles ähnlicher als einer Frau.

Vorhin, in der Eile, von seinem Besuch überrascht, hatte sie vergessen, ihre Alltagshaube aufzustülpen; der Ofenhitze wegen, die nichts zu wünschen übrig ließ, bedeckte sie ihr dünnes Haar am liebsten gar nicht, das, wie unter einem durchsichtigen Schleier, überall schon die Kopfhaut hell durchscheinen ließ und ihr jetzt hinten in traurigen kleinen Strähnen lose in den starken Nacken hing.

»Warum haben Sie eigentlich nicht geheiratet?« fragte Wera Petrowna plötzlich. Sie war aufgestanden, langte sich mit ausgestrecktem Arm ihre alte Tüllhaube von einem Nebentisch und that sie auf ihren Kopf wie eine Krone; »-- schon längst hätten Sie das vollbringen können, -- selbst im Auslande --«

»Einer Ausländerin würde es hier nicht behagt haben,« bemerkte Tomasow, eine Zigarette anzündend.

»Aha, -- also gegeben hat es dort doch eine!« bemerkte sie mit weiblicher Logik und ließ sich auf ihren vorigen Platz nieder, -- »nun, und hier --? -- Auch hier wüßte ich mehr als ein Genre, das ganz gut für Sie gepaßt hätte.«

Wera Petrowna musterte dabei ihr Gegenüber mit hellen, etwas ironischen Augen sorgfältig prüfend, während sie den Rauch ihrer Zigarette in langen Ringeln von sich stieß. »-- Ein Mann wie Sie --? Was wird denn den am heftigsten angezogen haben --,« sagte sie nachdenklich; »-- nichts Naives natürlich, -- etwas Pikantes. Möglicherweise irgend ein Typus der Frauen mit den Verführungskünsten --, die Frau als die große Verführerin und Lehrmeisterin auf schweres Lehrgeld, -- möglicherweise überhaupt ein Leben, das mehr verführt als befriedigt -- --. Wenn ich Sie mir so anschaue --«

»Ach, lieber Himmel, vor hundert Jahren vielleicht?« unterbrach er sie halb ärgerlich, halb belustigt.

Wera Petrowna griff resolut in das Kästchen und begann an Tomasows Statt, die Figuren auf dem Brett aufzustellen.

»Nun ja, das ist wahr: jetzt sind Sie bequem geworden,« gab sie zu, »-- und ich will auch nichts Indiskretes ausplaudern über das, was mir allerlei kleine Fältchen um Ihren Mund da und um Ihre Augen bereitwillig zu verstehn geben. -- -- Aber: nun zum Beispiel eine Ehe mit einer Mustergattin, -- dafür ist mitunter grade das russische Mädchen ein Prachtexemplar: liebevoll, heiter, nachgiebig, voll Tüchtigkeit und Tapferkeit --«

Tomasow nickte anerkennend.

»Schätze ich auch ungemein,« bestätigte er kurz.

»Und man sollte doch meinen, jemand wie Sie, der ganz gern herrscht, der müßte doch auch gern endlich sein eignes Haus um sich bauen, -- sein Leben breit ausbauen mit so einer russischen Frau -- von jener Sorte, der noch der Mann das Schicksal ist, das sie liebt, und dem sie gehorcht --«

»Ein schönes Glück!« bemerkte Tomasow spöttisch, »sein eignes Leben mit allen Unzulänglichkeiten und Defekten so festgenagelt zu sehen rund um sich, -- ein Wesen darin mit einer Miene umhergehn zu sehen, als sei das nun wirklich das Paradies --. Nein, für den Reiz danke ich. Ich danke für die kleine Art der Männertyrannei. Leicht genug zu herrschen, wo nichts zu beherrschen ist. Wozu?«

»Sieh da! Sie können sich sogar selbst verspotten,« entgegnete die Alte beifällig. »Das wirft mir ein ganz neues Licht auf Sie. Da begreif ich zum Beispiel schon besser, daß Sie mal, in Ihrer Jugend Blüte, für eins von den kleinen heldenmütigen Mädchen geschwärmt haben, die hier und da aus lauter edelm Fanatismus in unsre entlegensten und verarmtesten Provinzen als Lehrerinnen abgehn. Wie sah die aus? Mager, sehr mager, blaß, mit großen enthusiastischen Augen --? -- -- Aber geheiratet haben Sie das kleine Mädchen doch nicht --.«

»Möchten Sie nicht vielleicht Ihre diesbezüglichen Meinungen lieber für sich behalten?« meinte Tomasow grob, aber er lächelte.

»Wenn es Ihnen besser behagt, -- warum denn nicht?« sagte die Alte seelenruhig, »-- ich spiele ja viel lieber Schach. -- -- Aber das reine Wohlwollen treibt mich -- --, -- es ist wirklich merkwürdig, wie reichhaltig Sie sind, ich kann mir so ganz verschiedenartige Frauen recht gut neben Ihnen vorstellen --. Ist das nun Reichtum, oder -- oder ist irgend etwas nicht recht zum einheitlichen Ende gekommen --? -- -- Also spielen wir?«

Sie fingen endlich damit an, wie jedesmal, wenn Tomasow herkam. Erst mußte die Redelust der Alten ein wenig ausschäumen.

Wera Petrowna blieb indessen zerstreut. Sie machte Fehler auf Fehler. Zuletzt lachte sie kurz auf, sodaß sich die Oberlippe von den Vorderzähnen fast höhnisch hob, und äußerte ohne rechten Grund: »Die Zeiten ändern sich. Der Heldenmut auch. Jetzt ziehen es die kleinen Mädchen manchmal vor, ihre Mutter zu verlassen, um irgendwo in allem Behagen und mit viel männlichem Selbstbewußtsein zu studieren. So wie Marianne ihre -- --. Ein Glück noch, daß Sophie --«

»-- Sophie geht ebenfalls. Um Ostern. Heute hat Frau Marianne eingewilligt,« sagte Tomasow.

Wera Petrowna starrte ihn erst ungläubig an. Wie mit einem Schlage verschwand aus ihren Zügen alles Ironische und der spielende Spott und das versteckte Lachen. Schrecken und ein fast ehrfürchtiges Erstaunen stritten in ihrem lebhaften alten Gesicht um die Herrschaft.

Sie schlug laut die Hände ineinander.

»O du grundgütiges Seelentäubchen, meine einzige Marinka --! Was das sie kostet --! Und das sagen Sie mir erst jetzt, Sie Eisbär, Sie Feuerländer, Sie -- Sie -- --. Was das sie kostet --!« Sie hielt inne und starrte ihn wieder an. Man konnte deutlich sehen, wie angestrengt und durchdringend hinter ihrer Stirn und ihrem sich sammelnden Blick hundert Gedanken auftauchten. »Die Kinder fort!« sagte sie langsam, »-- beide Kinder, -- das ist ein ganz neues Leben, ein ganz zerbrochenes Weitervegetieren für sie oder -- --. Es ist eine vollkommne Einsamkeit, Vereinsamung, -- oder -- --? -- Marianne ist noch jung, -- sie ist noch immer jung --«

Tomasow, der unwillkürlich niedergeblickt und mechanisch mit dem Deckel der Zigarettenschachtel gespielt hatte, hob den Blick.

Eine kurze Pause lang schauten sie einander schweigend in die Augen, einer des andern Gedanken enträtselnd --.

Wera Petrowna rief plötzlich in fast klagendem Ton: »-- Ach Tomasow, wer verdient denn das aber, so viel Glück, wie diese Frau noch geben könnte, -- was für ein Mannsbild verdient denn das --?«

Er wollte etwas erwidern, aber sie unterbrach ihn gereizt: »Nein, schweigen Sie nur! Es ist schon so, -- ich weiß, ich weiß!« beharrte sie fast giftig.

Und plötzlich stand sie auf und fuhr mit der Hand durch die Figuren, daß sie alle umfielen.

»Es muß schon so sein! Die Jugend muß wohl immer erst heraus aus einem Menschen, -- da hilft nichts!« murmelte sie ergrimmt, und sie fing an, an ihrem Stock auf und ab zu gehn. Das Sitzen hielt sie nicht mehr aus.

Tomasow schob das Brett zurück und rauchte schweigend. Gegen die Sonderbarkeiten der Alten war er nachsichtig. Und viel lieber, als zu spielen, hing er jetzt seinen Gedanken nach.

Da hörte er sie sagen, ganz in Zorn: »-- Ist es nicht wie eine Löwengrube, -- so ein Menschenleben --? Man muß doch immer wieder hinein, -- immer wieder hinein --. Und was hat diese Frau nicht angesammelt in all den langen Jahren, -- all die unausgegebene Fülle -- --. Es ist sogar einerlei im Grunde: ob sie noch einmal neu anfängt mit dem Leben, oder ob sie einsam bleibt, -- diese ganze Fülle, die ganze Inbrunst reißt sie ja doch notwendig in die tausend Lebenskämpfe, wie unter brüllende Tiere --«

Nach einer Weile fuhr sie grollend fort: -- »Da ist nun Sophie, -- nun viel ist sie noch gar nicht, -- aber was bedeutet so ein Mensch mitunter nicht alles für seinen Mitmenschen! Daß sie bei ihr war, glich für Marianne alles aus, -- sänftigte das ganze Leben --. Manchmal genügt so wenig, -- so ein bißchen Menschennähe, um gar nicht zu merken, wie viel man noch in sich herumträgt, -- wie vieles man noch unter Schmerzen entladen soll. -- Erst wenn diese sänftigende Schutzdecke davon abgerissen wird, -- plötzlich steht man da wieder hart am Rande, -- ganz hart am Absturz -- mitten in alle Untiefen von neuem hinein -- unerbittlich hinein!« Wera Petrowna holte sich in ihrer Erregung die Haube vom Kopf herunter und lief fast auf und ab. »Gott meint es erst gut mit denen, die es hinter sich haben, -- hinter sich. -- -- Arme Marinka!«

Tomasow saß zurückgelehnt, mit dem Rücken nach ihr. Er vernahm wohl ihre Worte, aber gleichzeitig umfingen ihn andre, weit weniger düstere Bilder --. Und auch sie scharten sich um dieselbe Erwägung, wie um ein Leitmotiv dazu: »-- Marianne ist noch immer jung --«

Die Alte hinter ihm im Zimmer war still geworden. Auch ihr Stock berührte nicht mehr, im Takt aufschlagend, den Fußboden.

Tomasow empfand spontan, wie starkes Erleben und Erkennen hinter ihrer gewohnten Alltagsironie stehn, -- wie tief sie selbst in die Löwengrube hinabgestiegen sein mochte, -- und daß sie von dort herausgekommen war mit einem Herzen, das ganz wund war von zartem Mitleid und verstehender Furcht für andre --.

Er wandte sich zu ihr um. Sie saß im Stuhl am Fenster. Die Haube hielt sie noch wie einen wunderlichen dunkeln Knäuel in der Hand.

Und sonderbar hob sich dieser nackte Kopf von der hellen unfeinen Tapete des Zimmers ab, -- wie durchaus nicht hergehörig in diese banale Stube, -- wie nicht einem Mann und nicht einer Frau zugehörig, -- vielmehr einem geheimnisvollen Wesen oder

Unwesen, das nun dasitzt in den Wohnungen der Menschen, um dunkle Dinge zu weissagen --.

Ganz unbeweglich saß sie da. Und ihm wurde es fast unheimlich, so auf sie hinzuschauen. -- -- Als müßte er schnell, jetzt gleich, irgend einen Bannspruch, irgend einen Wahrspruch finden, -- der ihre finstern Gedanken, -- der den Lebensgedanken selbst -- in Freude löste. -- -- Oder als würde sie sich selbst langsam erheben, unmenschlich groß, und etwas Unerhörtes, Unüberwindliches sagen --.

-- In solcher Stimmung hört man als Kind Märchen erzählen -- --.

Tomasow erhob sich und trat zu ihr hin ans Fenster.

Da blickte Wera Petrowna auf. Sie sah auf mit dem welken, freundlichen Antlitz einer alten Frau, die sich Sorgen macht.

»-- Arme Marinka --!« sagte sie nur mit einer schwachen, bekümmerten Stimme.

=IV.=

»-- Also: Schluß für vierzehn Tage. Junge, klapp die Bücher zu und freu dich!« sagte Marianne zu ihrem Neffen nach Beendigung der französischen Montagskonversation.

Sie saßen schon bei der Lampe im Lernzimmer der ältern Kinder. Nikolai hatte beide Ellbogen aufgestützt und schob trübselig seine etwas breit geratene Unterlippe vor.

»Freu mich gar nicht. Aber auch nicht die Spur!« versicherte er; »worauf denn? Eine Menge Familientage, schrecklich lange Mittagessen, -- und zu Hause sitzen --. Ob man sich schließlich in der Schule ducken muß oder zu Hause -- --. Mußt du denn schon gehn?«

Marianne war heute so besonders angenehm gewesen, fast so lustig wie ein guter Schulkamerad, daher paßte es ihm nicht, daß sie schon ging.

»Du hast doch eine Menge Vergnügen in deinen Ferien! Ein undankbarer Junge, nicht wahr, Inotschka?« meinte Marianne.

Inotschka beugte sich über ihre Weihnachtsstickerei, die ihr heute wirklich Eingang zu der Montagsstunde verschafft hatte. An diesen Tagen heimlicher Arbeit ging vieles ungerügt durch.

»Ach, was weiß denn Ina! Ein Mädchen! Gut ist es doch nicht eher, als bis man groß ist und ein selbständiger Mann,« konstatierte Nikolai, griff verdrießlich nach seinen Büchern und verließ das Zimmer.

Inotschka antwortete ganz still: »Nein, so darf man nicht sprechen. Die Eltern bereiten uns so viel Freude, wie sie nur können. Wir müssen ihnen sehr dankbar sein.«

Dann sah sie jedoch sehnsüchtig zu Marianne hin und fügte in ganz anderm, drängendem Tone hinzu: »Warum ist es nur so, daß ihr diesmal nicht mit uns Weihnachten feiert? Ach, thus doch! Weißt du noch: voriges Jahr -- --!«

Marianne, die schon aufgestanden war, strich mit der Hand Inotschka über das weiche Haar, dessen feinen seidigen Strähnen man die Fülle, die sie enthielten, kaum ansah. Es lockte sie immer heimlich, dies feine Haar zu lösen und ganz anders zu ordnen.

»Das war ja nur ein Zufall voriges Jahr! Du mußt dich nicht so danach sehnen,« sagte sie sanft. »Sieh mal: ist es denn nicht überhaupt ein Zufall, daß ich hier in eurer Nähe lebe? Wie leicht hätte es so kommen können, daß ich im Auslande blieb. -- -- Und vielleicht -- -- vielleicht kommt es noch dazu, Inotschka.«

Die Kleine hatte ihre Stickerei auf den Tisch geworfen. Sie schaute mit erschrockenen Augen empor.

»Das -- das hab ich gefühlt --!« entfuhr es ihr heftig.

»Aber nein! Sei nur ruhig, meine kleine Ina, -- heute und morgen ist noch alles beim alten. -- -- Und übermorgen, im Handumdrehen, -- da ist aus der Ina schon ein großes, vernünftiges Mädchen geworden!« beschwichtigte Marianne sie tröstend.

Aber Ina war aufgesprungen. Sie hing sich Marianne an den Hals und brach hilflos in Thränen aus.

»Ich werde nicht groß! Ich werde nicht vernünftig! Alle Vernünftigen sind so gräßlich. Laß mich doch klein bleiben! Laß mich bei dir bleiben!«

Marianne blieb ganz stumm. Sie schlang nur ihre Arme um sie und küßte sie auf das Haar und auf die weinenden Augen. Dann, nach Minuten schweigender Liebkosung, beugte sie den Kopf tief zu Inotschka nieder und flüsterte ihr ins kleine heiße Ohr: »Sei still, mein Herz, ich komme jetzt oft und oft zu dir, -- so oft du mich nur wirst haben wollen --.«

Ina ließ sie los und blickte ungläubig auf. »Wirklich?! Sagst du es auch nicht nur so?«

»Nein. Ich sage es nicht nur so. Ich werde Mama um die Erlaubnis bitten, recht oft kommen zu dürfen, um mit dir zusammen zu sein.«

»Und glaubst du, daß -- --, meinst du, Mama wird erlauben, daß du so wirklich zu mir kommst -- --? Denn wenn ich mit den Großen dabei zusammensitzen soll -- --«

Marianne setzte sich auf Inas Stuhl und zog sie wie ein kleines Kind zu sich auf die Kniee.

»Mama erlaubt alles, was geeignet ist, dich froh und glücklich zu machen,« entgegnete sie zuversichtlich, und als sie Inas schüchterne Augen voll Zweifel auf sich gerichtet sah, fügte sie ernst hinzu: »Du denkst mit Unrecht, deine Mama enthielte dir dies oder jenes vor, und du wirst scheu, weil du meinst, vor verschlossnen Thüren zu stehn. Aber sie gehn noch alle auf, mein Liebling. -- -- Siehst du, davon und von vielem andern will ich dir erzählen, wenn wir so bei einander sind, wie jetzt.«

»Willst du mir von Mama erzählen, wenn du bei mir bist?« fragte Ina stockend und sah sie unsicher an.

Marianne streichelte sie mit einem feinen Lächeln voll Güte.

»Von uns Mamas überhaupt. Denn, weißt du wohl, wer das ist? Eine Mama, das ist jemand, der gewaltig reich geworden ist durch das Verlangen, recht viel zum Verschenken an seine Kinder zu haben. Aber die Kinder sind erst ganz klein, und dann jedes Jahr nur ein bißchen größer, und es dauert lange, bis sie ganz groß sind, sodaß sie wirklich alle die reichen Geschenke benutzen können. Daher muß Stück für Stück in festen Truhen verwahrt bleiben, und wenn die Mama aufschließt und nachschaut, was sich für ihre Lieblinge wohl schon eignet, dann darf sie sich doch nichts merken lassen von der Bescherung, für die es noch zu früh ist. Und dann sieht es den Kindern fast so aus, als hätte sie nichts übrig für sie. -- -- Aber alle ihre Truhen sind grade dann voll Gold. -- -- Jemand, der ungeduldig und sehnsüchtig zwischen lauter Truhen voll Kostbarkeiten umhergeht: das ist eine Mama. -- -- Weißt du es nun?«

Ina schmiegte sich fester an Marianne an.

»Und du hast auch solche Truhen, die du nicht aufmachst?« fragte sie, »-- du auch?«

»Ja, ich auch. Viele -- viele.«

»Aber einmal -- da springen sie alle auf! Alle?« Ina richtete sich mit verlangenden Augen auf Mariannens Schoß hoch.

»Alle -- alle!« versicherte Marianne mit unterdrücktem Jubel in der Stimme und legte ihre Arme um das kleine Mädchen. Man fühlte, daß irgend eine eigne große Freude oder Erwartung aus allen ihren Worten herausklang wie eine überströmende Wärme.

Inotschka lächelte, sie hatte leicht gerötete Wangen und sah unendlich zufrieden aus. »Was für wunderschöne Geschichten du aber auch weißt, Tante Marianne! Wirst du mir noch viele erzählen?«

»Ich werde dir gewiß noch schönere erzählen. Denn nun mache ich bald die allerschönste Truhe auf --«

»Für mich auch!« rief Ina vergnügt und klatschte in die Hände.

Plötzlich hielt sie jedoch inne. Sie ließ Marianne los und glitt von ihren Knieen hinunter.

»Da kommt Mama!« murmelte sie, »-- vorhin fuhr ein Schlitten vor --. Die Wohlthätigkeitsvorstellung muß jetzt auch schon längst vorüber sein --.«

Man vernahm etwas hastige Schritte und das Rascheln eines seidenen Kleides. Die Thür wurde nur ein ganz klein wenig geöffnet, Ottilie schob den frisierten Kopf an die Spalte.

»Bist du noch da, Marianne? Hast du Zeit --? Nein, Inotschka, mein Kind, laß dich nicht stören, du brauchst nicht zu erschrecken, Mama hat nichts gesehen, -- du sollst sehen, wie überrascht ich sein werde zu Weihnachten --.«

Marianne trat zu ihr heraus, in das Schlafzimmer der Schwester.

»Ich höre, du kommst aus der Oper, Otti?! Du und in die Oper, mitten am Tage? Du wirst ja noch ganz musikalisch auf deine alten Jahre,« bemerkte Marianne erstaunt.

»-- Der ›Troubadour‹ -- zu wohlthätigen Zwecken -- und mit dem durchreisenden Star als Gast. -- -- Fräulein Clarissa überredete mich. Herrgott, es passiert ja auch selten genug!« entgegnete Ottilie, noch in voller Theatererregung, und begann sich in aller Hast umzukleiden.

In einer Ecke am Tisch fütterte die Wärterin den Jüngsten, dem sie in russischem Kinderkauderwelsch zusprach, in der Nebenstube sah man die beiden ältern kleinen Brüder sitzen und artig Flittergold auf Nüsse kleben, als Schmuck für den Weihnachtsbaum.

Ottilie warf ihre geschnürte Seidentaille ab und ergriff Marianne am Arm.

»-- Ich sage dir: schön ist so was! Siehst du: in dem Augenblick, da lebt man! Wenn sie so füreinander sterben -- --« Ottiliens Augen strahlten.

Marianne lachte.

»Aber du, seit wann hast du so romantische Anwandlungen --? Du bist doch sonst die Nüchternheit selbst?«

»-- Sonst --? Ja, du lieber Gott, im wirklichen Leben ist doch kein Raum dafür. Da heißt es seine Pflicht thun, und damit basta. Das muß jeder anständige Mensch. -- -- Aber deshalb bewahrt man sich doch einen Winkel für das Ideale innerlich. Einen Winkel, wo das Leben anders wäre, wenn es nach uns ginge --: edel, höher, -- noch unbefleckt schön, -- kurz --«

»-- Romantisch?« fragte Marianne zweifelnd, mit einem gutmütigen Lächeln. Sie wußte selbst nicht, woher ihr Ottilie plötzlich so viel jünger geworden vorkam, ja fast unerwachsen jung, wie vor langen Jahren.

»-- Romantisch --!« wiederholte die Schwester etwas gereizt, während sie sich von Marianne in ihr Hauskleid hineinhelfen ließ, »-- meinetwegen nenn es so. Name ist bekanntlich Schall und Rauch. Aber du willst wohl andeuten: davon verstünde ich nichts, -- davon verstündest nur du was, -- einfach, weil du zufällig so blitzjung und so kopfüber eine Liebesehe geschlossen hast --. Aber was ist am Ende mit solcher Ehe los --?! Ich kann dir nur sagen, wovon ich nicht oft spreche: mein erstes Liebeserwachen war zwar lauter Verzicht, -- aber was ich hier innen besitze, --«

Sie sagte nicht, was sie innen besaß, sondern ließ ihre Worte unvollendet und knüpfte sich mit aufgeregter Hand das Kleid zu, wobei sie Mühe hatte, die richtigen Knöpfe zu finden.

»-- Du meinst doch nicht etwa den Husaren --?« wollte Marianne schon fragen, unterdrückte es jedoch.

Sie setzte sich neben den Toilettenspiegel, vor dem sich Ottilie ankleidete, und schaute die Schwester mit im Schoß gefalteten Händen gedankenvoll an.

Der harmlose Husar konnte so wenig dafür! Der mußte, wie es schien, nur ritterlich stillhalten bei allem, was ihm Ottilie so allmählich auf sein armes kleines Konto hinzuschrieb --. Vielleicht war es grade das Fehlen jeglichen starken Seelenaufruhrs in Ottiliens geordnetem Leben gewesen, das in ihr so allerlei emotionelle Restbestände aufgestapelt hatte -- --.

Ottilie mißverstand Mariannens Verstummen. Sie nickte ihr zu, wie von einer verborgenen Höhe.

»Ich glaube, du hast auch nur wenig Anlage dazu: du hast dich ja stets so ganz im Thatsächlichen ausgegeben und es überschätzt,« bemerkte sie und steckte sich ihr Häubchen fest. Auf ihren Wangen blühten noch zwei blaßrote Flecke.

Dabei hatte sie irgend eine halbmädchenhafte Kopfhaltung, irgend eine kleine Gebärde, -- fast wie unbewußte Koketterie einer Ungeübten, -- die mit einemmal Marianne wie eine lebendig gewordene Erinnerung aus beider frühester Jugendzeit durchfuhr.

Es paßte gar nicht recht hinein in das Wesen der jetzigen Ottilie, der musterhaft Fertigen, Korrekten! Aber dafür waren es nicht mühsam erworbene, sondern ihre eigensten einstigen kleinen Mienen und Gebärden --.

Sie besaßen etwas wunderlich Halbes, Verlorenes, -- wie wenn künstlich gestutzte Vögelchen zu fliegen unternehmen, -- dachte Marianne bei sich.

Und plötzlich umfaßte sie Ottilie von hinten und stand auf und küßte sie innig mitten ins erstaunte Gesicht. Ja, das war wirklich die Otti von ehemals, mit der sie so vieles geteilt, so kindisch geschwärmt hatte! Dann kam das ganze Leben dazwischen: das war von Marianne mit zitterndem Herzen, selig und schmerzlich, durchlebt worden, -- von Ottilie nicht --.

Und da ging sie nun in irgend eine alte Oper, und mit einemmal kamen allerlei hinuntergedrängte Sensationen herauf, -- unbegründet, etwas hysterisch, alle durcheinander: der Husar und die Ideale, Backfischhaftes und Erhabenes, Pathos und Koketterie --.

»-- Was fällt dir ein? Nein, aber Marianne, was fällt dir denn ein?! Man küßt sich doch nicht derartig mitten am Tage, ich muß jetzt an den Speiseschrank,« sagte Ottilie und wehrte sich.

»Und ich nach Hause. Aber, weißt du, Schwesterlein: ich komme nun oft, viel öfter --. Gib mir recht viel Raum. Laß mich viel mit euch sein, auch mit Inotschka --. Wer weiß, ob ich noch lange hier --« Marianne brach ab und wandte sich dem Kleinsten zu, sie hob ihn von den Knieen der Wärterin auf ihrem Arm hoch und liebkoste ihn, während er sie vergnügt ankrähte.

»Das ist schon recht, falls wir hier wirklich etwas haben, was dich, -- die viel Anspruchsvollere, -- fesseln kann,« erwiderte Ottilie; sie vermochte nicht den Uebergang ins Tagesleben ganz ohne Gereiztheit zurückzufinden.

»O! Ihr habt ja so vieles, was sich noch willig lieben läßt!« meinte Marianne leise und herzte noch immer das Kind.

»Ja, wie du das auch gleich sagst! Ich glaube wahrhaftig, Marianne, trotz deiner vielen Kenntnisse und Fähigkeiten, -- nimm mirs nicht übel: aber es ist im Grunde das einzige, was du zu thun weißt. -- Du sprachst von Inotschka: sag, glaubst du, daß sie den Pantoffel noch fertig stickt?«

»Der ist ja für dich, -- weißt du?« rief Marianne.

»Eben darum, weil er für mich ist, kann ich mich nicht gut drum kümmern. Wenn sie ihn vertrödelt, -- du verstehst, es ist mir nicht um den Pantoffel. Aber es wäre von übler Wirkung auf das Kind. Es gibt einem Kinde Selbstbewußtsein, seinerseits was zum Verschenken bereit zu haben. -- Von solchen Dingen hängt mitunter der moralische Halt im spätern Leben ab.«

Marianne seufzte. Sie setzte den Kleinen auf den Schoß seiner Wärterin nieder und ging mit der Schwester hinaus.

Sollte sie nun Ottilie erzählen: »Sophie geht Ostern auch zum Studium ins Ausland?« -- Würde Ottilie nicht fragen: »Was schenkt sie dir aber dafür wieder?« -- Ja, -- etwas Aehnliches würde sie fragen.

Wie konnte sie ihr das deutlich machen! Dieses Einssein mit den Kindern, dieses Mutterglück und diese drängende Hingebung in allen Fasern. Dieses Auskosten der vollen Liebe bis auf den letzten Tropfen. Denn jetzt waren sie zu Hause alle drei doch nur noch wie ein Mensch, -- nun erst ganz unzertrennlich.

Marianne ging fort, ohne etwas von der großen Neuigkeit mitgeteilt zu haben.

Trotz ihrer Ungeduld, heimzukehren, entschloß sie sich noch zu einem weiten Umweg.

Sie benutzte eine Pferdebahn, die nahe bis zu Tamaras kleiner Wohnung im Vorstadtviertel heranfuhr. Tamaras Mann öffnete ihr, mit einem listigen und erwartungsvollen Gesicht, -- er hatte seine Frau erwartet.

»Was, sie ist aus?« fragte Marianne stark enttäuscht, »ich muß sie so notwendig sprechen, und dachte sie zu dieser Stunde sicher zu treffen.«

»Ja, glücklicherweise ist sie fort, ich kann sie nämlich momentan gar nicht brauchen.«

Marianne bemerkte erst jetzt, wie er aussah. Im dicken Paletot, den Kragen hochgeschlagen, sogar warme Ueberschuhe an den Füßen, stand er da und rieb sich die Hände. In der That schien es kalt da drinnen zu sein.

»Was machen Sie eigentlich?! Frieren Sie vielleicht Ihre Vögel aus?«

»Ach nein, bei mir ist es warm. Wir müssen jetzt dort sitzen, zwischen den Vögeln, leider. Wir schlafen die paar Tage auch drin. Denn im Wohnzimmer, da wird jetzt nicht geheizt. Das ist wegen Weihnachten. Es soll nämlich wie ein Wald werden, -- Tamara stammt doch aus dem Walde. Sie darf jetzt nicht herein.«

Er öffnete die Thür zur Wohnstube, und Marianne erblickte in drei von ihren Ecken je einen großen Tannenbaum. Eine Küchenlampe stand am Boden. In dem ungewissen Schein, den das Lämpchen von unten her verbreitete, nahm sich die Bescherung seltsam genug aus, die zwischen den Tannen im Aufbau begriffen war.

Da näherten sich, fast lebensgroß in bemalter Pappe ausgeführt, die heiligen drei Könige einer kleinen Korbwiege, deren blaue Vorhänge dicht geschlossen waren. Was die Weisen des Morgenlandes darbrachten, bestand aber nicht in Gold oder Juwelen, sondern in den winzigsten Hemdchen, Jäckchen und Strümpfchen, die man sich denken konnte.

Die Bäume waren nicht geschmückt. Nur an dem schönsten, der sich über der Wiege erhob, hing Kinderspielzeug, -- Hampelmänner, Glöckchen an Knochengriffen -- und, wie ein Hinweis auf die Zukunft, schon ein erstes, zartes Paar Schuhe, lächerlich klein, aus rotem weichem Saffian, mit silberner Stickerei bedeckt.

In der Anordnung des Ganzen drückte sich ein unbeholfener jubelnder Ueberschwang aus, der Marianne ergriff.

Sie wandte sich zu Taraß und sagte leise: »Ich wußte gar nicht -- -- Aber es ist noch lange hin --«

Er nickte.

»Lange noch bis dahin,« bestätigte er, »aber, wissen Sie, ich kenne ja Tamara. In diesen Monaten wird sie schon ungeduldig sein: wann sie das alles arbeiten soll, -- ich bitte Sie, eine solche Menge! Und sie hat doch gar keine Zeit! Es mag ja schön sein, selbst daran zu nähen, nun aber, sie soll sehen: es geht auch so. Eine große Näherin ist sie überhaupt gar nicht. Sie sticht sich dreimal nacheinander in jeden Finger. Und allzufest näht sie auch nicht. -- Aber eine Mutter wird das sein! Ja, das ist noch eine Mutter!«

Er sah strahlend aus und trat frierend von einem kalten Fuß auf den andern.

»Darf ich Tamara nichts ausrichten? Soll sie zu Ihnen kommen?«

»Nein nein,« wehrte Marianne hastig ab, »ich komme lieber selbst wieder. Sagen Sie ihr nur: ich sei wegen des Vorschlages gekommen, den sie mir neulich im Auftrag des Berner Mädchenpensionates gemacht habe. Sagen Sie ihr: den wollte ich annehmen. Auf alle Fälle annehmen. Sie möchte mir helfen, die Sache so schnell als möglich ins reine zu bringen.«

Taraß schlürfte in den Ueberschuhen ihr voran zur Hausthür.

»Dann wird Tamara gleich alle Hebel in Bewegung setzen. Ich weiß, sie sprach davon. Und wir sind so froh, wenn wir Ihnen zeigen können, wie lieb wir Sie haben.«

Er küßte Marianne die Hand, und sie beugte sich auf seine Stirn. Ihr kam es vor, als sei alles bereits erledigt. Sie zweifelte nicht am Gelingen. Es mußte gelingen. Und sie war zu jedem Opfer bereit, zu jedem Nebenverdienst durch Stunden --.

Nur mit ihrem Kind zusammenbleiben mußte sie. Dann wollten sie auch schon Cita näher bekommen, -- mindestens näher als jetzt --.

Als sie sich wieder in die Pferdebahn setzte, schien es ihr, als führe sie schon weit, weit fort aus ihrem bisherigen, hiesigen Wirkungskreis.

Fast abschiednehmend spähte ihr Blick nach den einzelnen Häusern, die sie kannte. Da -- und da, -- und dort war sie zum Unterricht hingegangen. Nun aber wollte sie weit, weit fort, so weit wie ihre Kinder wollten.

All dies wurde Vergangenheit. Die Kinder allein, das war ja Heimat.

Kurz ehe sie den Bahnwagen verließ, stieg ein armer Krüppel ein, ein Stelzfuß in zerlumpter Kleidung.

Mit ehrerbietigem Blick bekreuzigte sich der Schaffner vor ihm und nahm kein Geld von ihm an. Diese Handlungsweise war allgemein üblich, solche Unglückliche durften fest darauf rechnen.

Als sich Marianne erhob, um auszusteigen, sah sie, daß jemand dem lahmen Mann ein Kupferstück zusteckte.

Da fuhr sie in die Tasche, faßte nach dem gehäkelten Seidenbeutelchen mit dem Tagesbedarf an Silberlingen, das sie grade frisch gefüllt hatte, und schob es im Vorübergehn dem Krüppel in die Hände.

Das gewährte ihr eine momentane Erleichterung. Sie wäre gern in irgend einer Weise aktiv geworden, aus ihrer weichen, warmen Stimmung heraus, -- wäre gern mütterlich geworden an irgend einem armen Wesen, aus ihrem Ueberfluß heraus --.

Und nun konnte sie nicht einmal für ihre nächsten Pläne etwas thun, weil sie Tamara verfehlt hatte. Aber ihr wollte es scheinen, als schade das alles nichts, wenn man ihr nur ringsum von der warmen Liebeslast abnahm --.

Oben öffnete ihr Stanjka. Doch im Wohnzimmer lief ihr Sophie entgegen.

»Cita ist nur für eine kurze Besorgung fortgegangen, Ma, sie kommt gleich wieder. -- -- Aber du bliebst so lange fort, -- ach, ganz schrecklich lange, wo warst du nur noch?«

Marianne drückte sie an sich.

»War das so schlimm? Du bist wohl ungeduldig geworden?«

»Ja, Ma. Jetzt möchte ich jede Minute bei dir sein. Das ist doch ganz natürlich, -- immer, immer.«

»Und wenn wir uns nun nicht trennten, -- wenn wir beisammen blieben, du mein Herzenskind!« murmelte Marianne.

Es kam ihr fast gegen ihren Willen auf die Lippen. Sollte sich Sophie unnütz quälen, -- und wären es auch nur Tage --, um der Trennung willen, die nach ihrer Ansicht bevorstand?

»Ach ja, Ma!« rief Sophie innig, jedoch gleich darauf schien sie ein plötzlicher Schreck zu durchfahren. »-- -- Du meinst doch nicht, -- ich soll doch nicht --«

Sie war ganz blaß geworden.

»Nein, o nein!« sagte Marianne schnell, »wie kannst du das glauben! Nichts wird rückgängig gemacht. Aber denke dir, mein Liebling, denke dirs nur als eine noch nicht gewisse Möglichkeit: wir blieben trotzdem beisammen, -- in einem kleinen Städtchen zum Beispiel, -- etwa in den Schweizer Bergen --«

Sophie machte sich sichtlich beunruhigt frei.

»-- Warum denn ein so ganz kleines Städtchen, Ma --?«

»Ich meine natürlich ein Universitätsstädtchen.«

»Ja ja, aber wenn auch --. Daß es so gar klein sein soll --? Warum denn eigentlich nur?«

»Stell dir zum Beispiel vor, dort wäre eine Mädchenpension, die ich zu leiten hätte, -- eine solche ist nämlich in Bern, -- lauter halberwachsne Mädchen --«

»-- Aber -- das wäre ja gräßlich, Ma!« fiel ihr Sophie ängstlich ins Wort.

Marianne hielt einen Augenblick inne.

Sie suchte mit plötzlicher Bangigkeit Sophiens Blick.

»-- Wäre das so gräßlich, -- Sophie?«

»Nein, -- das heißt: es wäre ja wunderschön natürlich, -- aber, -- ach nein, Ma! das kann ja doch gar nicht dein Ernst sein?«

Marianne versuchte zu lächeln, aber sie fühlte, daß ihr mitten in diesem schwachen Lächeln die Lippen kalt wurden.

»-- Nur so eine Idee, Kind,« sagte sie mühsam.

»Siehst du, das dachte ich.« Sophie küßte sie heftig und lachte beruhigt: »Das wäre ja auch gar nichts, nicht wahr? Denke nur: so eine Mädchenpension, -- Hammelherde, -- huh! Da müßten wir uns ja immer nach den Zimperliesen richten. Wenn du da Stunden gäbst und von allen möglichen Leuten abhingest, wäre alles gleich so gebunden, -- so wie hier --. -- -- Und übrigens, solches Kleinstädtchen doch auch für dich im Grunde recht öde, -- nicht?«

Marianne nickte, ohne Sophie aus den Augen zu lassen, die ihr unleidlich brannten und stachen von den bemeisterten Thränen.

»Ja ja, Sophie. Daran, ob es öde wäre, hab ich so gar nicht gedacht --. Wenn ich mir das überlege, ist es also wohl nichts damit.«

Sophie wurde wieder ganz heiter.

»Nein, was du aber auch für eine Phantasie hast, Ma?« meinte sie neckend und setzte sich der Mutter auf den Schoß. Sie war voll kleiner Zärtlichkeiten.

Nun wollte sie Ma auch ordentlich erzählen, wie sie sich das Leben dächte, mit Cita zusammen, in Berlin, wo Cita ja so vortrefflich aufgehoben sei und schon Beziehungen habe, und wo sie es nun ebenso gut haben werde. Beziehungen nämlich, das ist wichtig --! -- -- Eine Menge interessanter Einzelheiten plauderte ihr Sophie redselig vor.

Marianne saß müde in ihrem alten Lutherstuhl.

Sie hörte immer mit dem gleichen Anflug von Lächeln zu, es war wie erstarrt auf ihrem Gesicht.

Das also war das weitaus Schönere, wovon Sophie träumte. Und das hatte sie ja nun endgültig den Kindern gegeben, ihnen erlaubt. Mehr zu geben hatte sie nun überhaupt nicht. Nein: nur sich selbst noch hinzugeben hatte sie wollen. Sie selbst jedoch, -- ja sie selbst -- lehnten sie leise ab --.

-- Marianne überfiel plötzlich, mitten in Sophiens Hinplaudern, eine jähe Furcht, sie könnte mit einemmal -- jetzt gleich -- etwas Gräßliches, Grelles thun müssen, entweder laut schreien oder gar lachen --.

Besonders das letztere: jawohl, grell und gell lachen --.

In der Furcht davor brachte sie kein Wort heraus.

Zum Glück kam Cita nach Haus, eh es Sophie auffiel.

Als sie zu ihnen ins Wohnzimmer trat, sprang Sophie vom Schoß der Mutter heiter auf.

»Denke nur!« rief sie der Schwester ganz unbefangen entgegen, »Ma und ich sitzen hier gemütlich und malen es uns eben aus, wie das sein würde, wenn wir in ein ganz kleines Universitätsstädtchen zögen, anstatt nach Berlin. Und wenn Ma dort gar eine Pension leitete, -- und -- und wir Sonntags nachmittags mit im Zuge der Mädchen vor dem Thor spazieren gingen --«

Sie erzählte es ganz wie einen Scherz. Und ganz wie über einen Scherz lachte Cita mit ihr.

»Uff!« sagte diese dann, die Handschuhe abstreifend, und warf sich in den Schaukelstuhl, -- »wie gut ist es hier bei dir, Ma. Ja, das wird Sophie schon noch vermissen! Sie muß sich eben erst gewöhnen, man lernt es aber. Bis jetzt redet sie nur so hin. Wenn sie nur erst ordentlich in ihrem Studium drin ist --«

Marianne richtete ihre Augen müde und groß auf ihre Aelteste.

»Wenn es nur so ist, Cita, daß man dann nichts mehr vermißt,« sagte sie leise, mit matter Stimme, »-- denn das meint ihr doch wohl nicht, -- das kannst du doch selber nicht wollen: so ein Fachstudium, und nichts mehr dahinter und darüber --. Etwas so Spezielles, etwas so Hartes --. Du mußt nicht vergessen, wie sehr Sophie, -- und früher auch du, -- euch in einem allseitigern, harmonischern Ganzen geistig angeregt habt. Es schloß ein Studium nicht aus, aber das beseelte Leben ging doch noch drüber --.«

»Es war einfach dilettantischer,« bemerkte Cita ruhig. Sie hatte ernsthaft zugehört, während sie leise schaukelte und ihre Handschuhe bald zurollte, bald in alle einzelnen Finger auseinanderbreitete.

Marianne lehnte sich erschöpft zurück. Sie hatte sich gewundert, woher ihr nur so viele Worte kamen. Als ob sich ihre Zunge löste und selbständig spräche --. Aber als sie einsah, daß diese Worte ohne Wirkung waren, gab sie es auf, zu widersprechen.

Cita nahm ihr Schweigen wie ein leises Gekränktsein und fuhr rasch fort: »Ja, süße Ma, du hast sicherlich recht. Aber, siehst du, was du so das ›beseelte Leben‹ und ›das Allseitigere‹ in der geistigen Anregung nennst, das werden wir ebenfalls haben. Das Fachstudium wird bei weitem nicht alles sein, sondern der ganze Kreis der Interessen in der Frauenbewegung. Das wird uns frisch und kampflustig erhalten. Sieg der modernen Frau! Das soll die Losung sein. -- -- Hier konnte Sophie diesen belebenden Geist

unmöglich aufnehmen. Uns fehlte hier ja auch der laufende Zusammenhang mit allem Modernen. Wenn man aus dem Auslande kommt, spürt man das arg, du kannst es glauben! Nun, aber es schadet weiter nichts: wir holens schon nach.«

Sie erhob sich aus dem Schaukelstuhl, kam zur Mutter, bückte sich, küßte sie auf den Scheitel und sagte mit fast mütterlicher Zärtlichkeit im Ton: »Du unsre süße Ma! hier ist es einzig und allein schön, weil du hier bist. Vielleicht würdest du dich in einem andern Rahmen nicht mehr wohl fühlen. Und du machst alles schön rings um dich her. Aber wir können jetzt nicht nur auf das Schöne achten.«

Dann richtete sie sich auf, verschränkte die Arme auf dem Rücken und stellte sich nachdenklich musternd vor das Bücherregal.

»Siehst du, Sophie, -- dort hinein schaffen wir dann auch Ma neue Bücher, -- nicht an Stelle der alten, aber mindestens zwischen die alten. -- -- Man kann auch nicht immer nur Dante und Homer und Shakespeare und Goethe und ähnliche Herren lesen. Nicht wahr, Ma?«

Marianne saß ganz still und lauschte. Sie lauschte noch, als gar keine Rede mehr kam, und die Schwestern miteinander in den Büchern zu kramen anfingen, wobei Sophie auf dem Boden saß und Unsinn trieb.

Sie lauschte in alle geredeten Worte tief hinein --. Denn daraus klang ja nicht nur die naive Ablehnung Sophiens, nein, etwas viel Tieferliegendes hörte sie immer deutlicher heraus, -- etwas auf dem verborgenen Grund aller dieser Worte --.

Sophiens Gefühl war so ganz unwillkürlich gewesen. Aber es verriet, daß Mutter und Kinder ganz und gar nicht eins waren, eines Wesens, -- daß das ein bloßes Trugbild war, ein Traum. Die arme Sophie konnte nichts für ihren naiven Egoismus, -- Cita, die sagte es ja: sie waren etwas andres, wollten etwas andres, strebten anderm zu, als die Mutter --.

Der Mutter gehörten sozusagen nur noch Wesensreste aus der Kindheit, -- nicht mehr der entwickelte Mensch. Dem wurde sie leise fremd -- fremd -- fremd. Von dem wurde sie mit dankbarer Nachsicht geliebt. Notwendig blieb sie ihm nicht mehr.

Wahrscheinlich ging das immer so zu. Auch dann, wenn das Muttersein das gesamte Wesen eines Menschen aufgesogen und ausgemacht hatte --? Auch dann, wenn er sich mit seiner ganzen tragenden, nährenden Lebensfülle den Kindern einverleibt hatte --? Ja, auch dann. Auch dann blieb er wie ein blutendes, losgerissnes Stück am Boden liegen, allein liegen, -- ohne es ändern zu können -- --.

Cita hatte ja im Grunde recht: während die Mutter hier umherging und Stunden gab, vermochte sie nicht zugleich die Wege weiterzugehn, die sich nun den beiden öffnen sollten, -- die Wege neuer Zeiten, einer neuen Generation --. Und wohin die führen würden? Ob nicht zum entgegengesetzten Ende dessen, was sie mit heißester Inbrunst für ihre Kinder erfleht und selbst in ihrem ganzen Leben demütig zu verwirklichen gestrebt hatte?

Ja, vielleicht, -- wer konnte es wissen --? Ihr Urteil und das der Kinder würde sich in diesem Punkt wahrscheinlich entgegenstehn. Welche Instanz wollte über sie richten?

Mariannens Gedanken verschwammen, schmerzgefoltert, undeutlich ineinander. Noch hörte sie die beiden plaudern und lachen und sich gegenseitig Stellen aus Büchern vorlesen.

Ihre Arme waren wie gelähmt. Die Stimmen schienen ihr von weit, weit her zu kommen. Konnte sie die Arme nicht mehr ausbreiten, ihre Mädchen darin zu umfangen? Konnte sie ihnen denn nichts, gar nichts zum kostbaren Besitz und zum Leitstern mit auf den Weg geben von alledem, was zu gewinnen ihres Lebens Inhalt gewesen war --?

Weit, weit gingen sie fort --. Und plötzlich kamen Marianne, -- seltsam und leise, wie ein Raunen von Wind zwischen Blättern in der Nacht, -- Klänge aus einem Lied, -- aus einem Wiegenlied, der Dichtung eines Dichters von heute mit dem klaren Erkennen von heute. Es waren nur einzelne abgerissne Klänge, und während sie ihnen lauschte, wußte sie schon nicht mehr, ob sie sie nicht nur weinte --.

* * * * *

»-- Blinde, so gehn wir, und gehen allein, Keiner kann keinem Gefährte hier sein.

Schlaf mein Kind, und horch nicht auf mich! Sinn hats für mich nur, und Schall ists für dich!

Schall nur, wie Windesweh'n, Wassergerinn, Worte -- vielleicht eines Lebens Gewinn. Was ich gewonnen, gräbt mit mir man ein: Keiner kann keinem ein Erbe hier sein --.« *)

*) Aus Richard Beer-Hofmann, Pan 1899.

* * * * *

Die jungen Mädchen bemerkten gar nicht den Augenblick, wo Marianne das Zimmer verließ.

Erst als es hastig im Vorflur schellte, und gleich darauf Stanjka hereinkam und Tamaras Besuch meldete, blickten sie sich erstaunt nach Ma um.

»Eben war sie noch hier,« versicherte Cita, während Sophie den Gast hereinzog und unterhielt; »-- Ma, hör doch! Tamara ist gekommen!«

Marianne öffnete die Thür des Schlafzimmers, wo sie allein gesessen hatte. Sie ließ Tamara dort eintreten.

Diese fiel ihr um den Hals.

»Liebste Marianne Martinowna! Eben komm ich nach Hause, und Taraß erzählt mir --. Mein erster Gedanke: gleich hierher! Ich habe gar nicht erst abgelegt. -- -- Es ist allzu wichtig: natürlich muß die Sache gleich ins reine gebracht werden --.«

»Wie gut bist du!« murmelte Marianne. »-- Du weißt, daß Sophie zu Ostern --«

Tamara nickte.

»Sie sagte es mir soeben. Ja, ich dachte mir, daß so etwas der Grund sein würde. Wie könnten Sie sich von den Mädchen trennen, -- wie können die Mädchen Sie entbehren! -- -- So muß es denn sein, daß wir Sie aus unsrer Mitte verlieren.«

Marianne erwiderte nichts darauf. Sie saß neben einem kleinen Tisch, worauf eine einzelne Kerze brannte, und blickte an Tamara vorüber.

Tamara wurde sich erst jetzt dessen bewußt, daß irgend etwas an Marianne anders sei als sonst. Etwas so wunderlich Eingefrornes, Steifes.

Sie hatte sich nahe zu ihr gesetzt und faßte jetzt unwillkürlich besorgt nach Mariannens Händen, die ruhig im Schoß lagen.

Da sagte Marianne: »Weißt du, -- halte mich nicht für die wetterwendischeste Person, die es gibt. Aber seit meinem Gespräch mit deinem Mann hab ich mirs anders überlegt. Ich halt es für unmöglich, fortzugehn.«

Tamara sah sie erstaunt und ungläubig an.

»Aber warum?!«

»-- Diese ganze ungeheure Veränderung! Das schwierige Einleben dort. Wer weiß, ob wir alle drei es nicht später bereuen würden --. Es war eine erste Aufwallung, weißt du, aber -- -- die ist ganz vorüber.«

Tamara schwieg. Wie sie Marianne so dasitzen sah, bei dieser einzelnen Kerze, auf dem Rohrstuhl, -- da erschien sie ihr plötzlich wie eine Gefangene zwischen den Wänden des eignen Zimmers -- --.

Hinter Ma, über dem Bett, hing die Totenmaske ihres Gatten, daneben, wie ein Schmerzensschrei, Vogelers Radierung: das greise Paar, das in den Frühling hinausblickt.

Tamara sagte halblaut, tief betroffen: »Ach, Liebste, ich kann es nicht glauben. Wie -- ja wie wollen Sie alle drei denn so ohne einander auskommen? Ist das nicht das Wichtigste --?«

Ma lächelte.

»Ich denke, ganz gut. Weißt du, Tamara, eins muß man durchaus lernen, -- merke du dirs auch: die Dinge nicht zu weit zu treiben. Die Gefühle sich nicht über den Kopf wachsen zu lassen. Alles muß schließlich eine Grenze haben. Wenn man das gelernt hat, geht wirklich alles ganz leicht, -- viel leichter.«

Tamara stand auf.

»-- Also ist es wirklich entschieden. Nun, ich weiß nicht, ob ich mich freuen darf. -- -- Ich muß jetzt nach Hause eilen, Taraß wartet auf mich. -- Aber -- sagten _Sie_ diese Worte, Marianne Martinowna? Sie, die doch immer so ganz innig in ihrem Gefühl lebte, wie in einer großen unteilbaren Freude --.«

Marianne entgegnete rasch, mit plötzlicher Bitterkeit: »-- Kein Freudenbecher, der nicht zum Leidenskelch wird, wenn man ihn bis zur Neige leert! Nein nein, kein einziger, -- und vielleicht am wenigsten von allen das vielgepriesene Mutterglück.«

Sie erhob sich, um Tamara hinauszugeleiten. Da begegnete sie deren still und ernst auf sie gerichteten Augen, und sie gedachte mit einemmal dessen, daß diese Augen ja eben jetzt in grenzenloser seliger Erwartung dem zukünftigen Mutterglück entgegenschauten --.

Sie dachte an Taraß und seine strahlende Freude und an das kalte Zimmer mit den Tannen, der Korbwiege und dem Kinderspielzeug --.

Marianne umarmte die junge Frau plötzlich, aber ganz zaghaft, wie eine heimlich Geweihte, sie nahm ihre Hände zwischen die ihren, drückte sie an ihr Gesicht und murmelte hilflos: »-- Verzeih mir, -- ach verzeih! Hör nicht auf mich. -- -- Wie gut bist du doch. Hast da den weiten Weg in der Kälte gemacht --. Deck dich im Schlitten gut zu, hörst du --? -- -- Du mußt jetzt solche Wege vermeiden, -- dich in acht nehmen --.«

Tamara wurde dunkelrot. Sie küßte Marianne herzhaft, mitten auf den Mund.

»Ach,« sagte sie, und ihre Stimme klang ganz hell von viel Glück, »ich weiß es ja, -- ich wußt es ja: Sie sind doch noch ganz dieselbe, -- unverändert dieselbe und werden es immer bleiben. -- -- Es genügte nicht, daß Sie mir Schulunterricht gaben und noch manchen andern, schönern Unterricht: ich hab es ja Ihnen allein abgeguckt, wie man eine gute Mutter wird, -- so eine von Herrgotts Gnaden --. -- -- Und mein kleines Kind, das bring ich zu Ihnen, daß es hier heimisch werde von Anfang an, und es soll Großmutter sagen lernen von Anfang an --.«

Marianne geleitete sie hinaus und ging nicht mehr ins Schlafzimmer zurück. Der Theetisch wurde schon gedeckt; wie immer saß sie beim Abendthee mit ihren beiden Mädchen zusammen und plauderte mit ihnen.

Aber eine undenkliche Mühe kostete sie ein jedes Wort, das harmlos und heiter klingen sollte wie immer --. Und während sie gleichgültige Dinge sprach, dachte sie immer denselben Gedanken: »Ist es im Grunde nicht wahr? Haben sie denn nicht recht? Sie lassen sich erfüllen von allem, was sie vorwärts bringen mag, ich aber, -- habe ich nicht jahraus, jahrein nur ein paar immer gleiche Sorgen mit mir herumgetragen: tägliches Brot beschaffen, -- Lektionen vorbereiten, -- und wieder das tägliche Brot, und wieder die Lektionen --. Ich habe mich bemüht, es so gut zu machen, wie ich nur konnte: und da hat das Wenige genügt, -- da haben diese anderthalb Gedanken schon genügt, -- um alle Kraft aufzuzehren --. Oder hatte ich nicht genug Kraft -- --?«

Und langsam sank die Bitterkeit von ihrer Seele, um nur einer tiefen, demütigenden Entmutigung den Platz zu lassen. Bitterkeit vermochte ihre Seele nicht lange zu ertragen: die Entmutigung nahm sie schweigend auf.

Als die Mädchen sahen, daß die Mutter nicht recht heiter gestimmt war, schoben sie es auf die Ermüdung durch den anstrengenden Tag, und unwillkürlich suchten sie ihre eigne Fröhlichkeit etwas zu dämpfen, die sich mitunter allzuhell Luft machte.

Marianne merkte es, und das Herz zog sich ihr zusammen. »Sie wagen nicht mehr, mir zu zeigen, wie glücklich sie über die Wendung der Dinge sind, -- sie fürchten mich damit zu kränken, -- sie verhalten es lieber vor mir, bis sie unter sich sind,« dachte sie.

Und die kleinen Zärtlichkeiten ihrer Kinder thaten ihr nur weh. Sie fühlte etwas Nachsichtiges aus allem heraus, -- etwas Absichtliches. Nein, lieber noch wollte sie es sein, die sich vor ihnen verstellte, und mit ihnen froh sein.

Aber sie konnte es nicht.

Am nächsten Morgen beim Frühstückstisch wurde Cita doch trotz Mariannens Bemühungen stutzig. Sie meinte so genau zu wissen, daß die Mutter heute fast keine Lehrstunden mehr zu geben habe, und dabei schien sie sich doch so zu beeilen, um nur fortzukommen.

Marianne behauptete sogar, sie könne noch nicht zum zweiten Frühstück zurück sein, sondern erst spät am Nachmittag, sie möchten nicht auf sie warten.

Sophie machte ein pfiffiges Gesicht, offenbar hatte Ma heimliche Weihnachtsbesorgungen vor. Aber Cita blickte stumm und mit einem zweifelnden, besorgten Ausdruck vor sich nieder. Wohin ging die Mutter? Und warum sah sie dabei so gequält und müde aus? Ging sie vielleicht, um wieder mit Tomasow etwas zu besprechen? Und diesmal vielleicht etwas, womit sie ihren Kindern Leid anthat --? Ach, ginge sie doch nicht zu ihm! -- --

Marianne atmete tief auf, als sie endlich auf der Straße stand.

Langsam machte sie einen weiten Gang im klaren Winterwetter, dann raffte sie sich zu einem Besuch bei einer aus dem Schuldienst scheidenden Kollegin auf, von der sie sich erst in den Feiertagen hatte verabschieden wollen. So kam allmählich die Zeit für die einzige Stunde heran, die sie heute geben mußte.

Dabei weilten ihre Gedanken zu Hause. Alle Räume ihrer kleinen Wohnung durchschritt sie, aber, als sei ihr Blick verhext, erschienen sie ihr alle schon öde und leer. Sie erwog schon, wo, -- in welchem Raum, an welchem Platz -- sie wohl sitzen würde, so ganz allein --. Kleinigkeiten erwog sie angestrengt: ob man die hohen Blattpflanzen, ihre Lieblinge, nicht fortgeben sollte, da sie nicht auf ihre Pflege achten konnte, wenn sie so von Stunde zu Stunde lief -- --.

Von ihrer einzigen Unterrichtsstunde wäre Marianne fast aus Zerstreutheit nach Hause gegangen. Plötzlich fiel ihr jedoch der Weihnachtsbaum ein, der sich so groß und anspruchsvoll mitten in ihrem Zimmer erhob, -- als erwarte er sie da förmlich mit herausforderndem Hohn. -- -- Morgen war schon heiliger Abend. Da würde man ihn sogar noch schmücken müssen. Denn das wollten die Mädchen ja ihretwegen gern thun, obschon es ihnen ein bißchen lästig war, -- sie selbst hielten nichts auf solche Kindereien --.

Wie recht sie hatten! Wie froh wäre sie jetzt gewesen über ein sang- und klangloses Weihnachten!

Nein, sie vermochte nicht heimzugehn und sich an den gedeckten Frühstückstisch zwischen ihre beiden Kinder hinzusetzen --.

Frierend und unschlüssig, wie obdachlos, stand Marianne auf der Straße im Winterwinde.

Sie, die sich so auf die Ferien gefreut hatte, sie, die es so haßte, sich Tag für Tag draußen herumtreiben zu müssen, sie stand jetzt da, um den Ihrigen Lehrstunden vorzutäuschen, die sie gar nicht zu geben hatte --.

Einmal fiel sie durch ihr zauderndes Stehnbleiben auf. Irgend ein Straßenflaneur beugte sich vor, um sie deutlicher zu sehen --. Es war mitten im Menschengetriebe unweit der Schmiedebrücke; Marianne durchquerte den Fahrdamm, um in eine der stillern Seitenstraßen einzubiegen, als sie zwischen den dahinhastenden Menschen Tomasows Gestalt erkannte.

Er schritt langsam neben irgend einem Bekannten. Als er Marianne auf sich zukommen sah, verabschiedete er sich jedoch von ihm und ging ihr erfreut entgegen.

Leise schob sie ihren Arm in den seinen.

»Danke!« sagte er lächelnd. »-- Offenbar auf Weihnachtswegen?«

Sie schüttelte den Kopf.

»Nein. Ich bin todmüde. Ich möchte irgendwo eintreten, wo ich etwas essen könnte.«

»Sie wollen nicht erst den langen Weg nach Haus?« Er besann sich. »Gehen wir zu Philippow? Oder ziehen Sie ein Restaurant vor?«

»Keins von beiden. Ueberall könnten Bekannte sein. Ich möchte dort in der Seitenstraße in eine der kleinen billigen Theebuden, wo kein Mensch hinkommt.«

Sie suchte ihn die paar Schritt weit hinzulenken.

»Aber, Ma! Da geht man mit einer Dame nicht hin.«

Marianne ließ geschwind seinen Arm los.

»-- Dann lassen Sie mich allein hingehen -- Ich nahm wirklich zu dem Zweck Ihre Begleitung an,« sagte sie und blickte aus so sonderbar müden Augen auf ihn, daß er sofort nachgab.

Er zuckte die Achseln.

»Nun es sei, also wie Sie wünschen,« meinte er zögernd und führte sie dem kleinen Lokal zu, das mit einem breiten grellblauen Schild zum Eintritt lud. »Schließlich ist es eine warme Ecke, wie eine andre, wenn sie auch ein bißchen tief im Erdgeschoß drin liegt.«

Im Innern der Theestube hingen blendend saubere Leinwandvorhänge an den niedrigen, fast quadratischen Fensterchen, und auch das weiße Holz der simpeln Einrichtung sah so weiß und sauber aus, als müsse es Seifengeruch ausströmen. Im ersten Raum dampften ein paar mächtige blanke Kupfersamoware auf dem Schenktisch, und an den Wänden lagen bis hoch hinauf unendlich viele Schwarzbrote aufgestapelt.

Doch gab es auf Wunsch auch helles Gebäck, sowie die volkstümlichen Pastetchen mit Grützfüllung, und Tomasow bestellte davon, dessen sicher, sie vorzüglich bereitet zu finden. Der bedienende Gehilfe im weißen Leinwandkittel und hohen, dermaßen glänzend gewichsten Kniestiefeln, daß man sich in ihnen beinahe hätte spiegeln können, brachte das Verlangte in den schmalen Nebenraum, wo Marianne schon im Hintergrunde an einem der länglichen ungestrichenen Holztische saß.

Nur zwei Frauen aus dem Kleinbürgerstande, mit bunten Kopftüchern und kurzen Schaffellpelzen, tranken beim Fenster ihren Thee, wobei sie die gefüllte Untertasse auf den gespreizten Fingern der rechten Hand balancierten; schweigend, mit einer gewissen Feierlichkeit und ohne um sich zu sehen, nahmen sie einen heißen Schluck um den andern.

»Hier ist es gut!« sagte Marianne.

Sie sah abgespannt aus, und dabei brannte ihr das Gesicht vom Winde. Die Hitze, die der mächtige Kachelofen im geschlossnen Zimmerchen ausströmte, machte es noch fühlbarer.

Marianne empfand wirklichen Hunger, er war ganz plötzlich und fast mit Gier erwacht, als sie beim Eintreten das viele ringsum an den Wandborten aufgeschichtete Brot sah. Aber wie nun ihr Frühstück vor ihr stand, vermochte sie ebenso plötzlich nichts mehr zu essen.

Sie bückte sich über ihr Theeglas, aus dem dicht vor ihrem Gesicht der Dampf in die Höhe stieg, und folgte mit dem Blick gedankenlos seinen Windungen. Dieses Gefühl von sich nachgebender Schwäche war merkwürdig angenehm.

Tomasow betrachtete sie aufmerksam.

»Sie gefallen mir ganz und gar nicht!« äußerte er; »aber eigentlich hätt ich mir das ja schon vorgestern selbst voraussagen können --«

Marianne hob verwundert den Kopf.

»Was denn --?« fragte sie zerstreut.

»Daß der erste Kraftaufwand nicht vorhalten, -- daß die Stimmung zunächst sinken würde --. Sie haben sich seelisch bis zum äußersten anspannen müssen, und jetzt kommt der Rückschlag.«

Marianne rührte mit ihrem Löffel im Thee herum. Ihr fiel ein, daß Tomasow ja so gar nichts vom gestrigen Tage wußte. Ueberhaupt nichts von der heimlichen Hoffnung, die sie ja allein so tapfer hatte erscheinen lassen, -- noch auch von der großen Bitterkeit hinterher.

Es war etwas ganz Ungewohntes für sie, daß er nicht vollen Bescheid wußte und dementsprechend urteilte. Aber nur nicht davon erzählen! Sogar ihm nichts! Was konnt es denn helfen?

Tomasow stützte einen Arm auf, und sich näher zu Marianne hinwendend, mit dem Rücken gegen das Fenster, bemerkte er halblaut: »Frau Marianne, jetzt ist es an der Zeit, daß Sie mir mehr Machtvollkommenheit geben --. Vollmacht, Sie ganz anders als bisher in Obhut zu nehmen, zu pflegen, abzulenken, zu beaufsichtigen, -- kurz: um Sie zu sein --«

Sie faßte seine Worte nur ungenau auf, in ihre Kümmernisse klangen sie aus solcher Ferne herein, daß sie keinerlei verborgenen Sinn hinter ihnen vermutete.

»Ich weiß, Sie sind immer gut!« sagte sie nur freundlich.

»-- Gut --?! Nein, Marianne, mit meinem Gutsein hört es nun auf. Glauben Sie nur, es ist mir nicht immer leicht gefallen ›gut‹ gegen Sie zu sein, Ihr guter Freund zu sein -- alle die Jahre. Jetzt aber, wo Sie allein bleiben, wo sich Ihre Töchter ihr eignes Leben bauen, da will ich ein andres Recht, als das der Güte: das Recht, auch ein Leben aufzubauen -- Ihnen und mir.«

Er sprach noch immer halblaut, jedoch rasch und bestimmt, und in seiner Stimme vibrierte tief gedämpft ein Ton, den er Marianne gegenüber noch nie angeschlagen hatte.

Sie schrak aus ihrer Müdigkeit auf, ihr Blick streifte Tomasow wie erwachend und noch verständnislos erstaunt; als sie jedoch dabei seinen fest auf sie gerichteten Augen begegnete, geriet sie in Verwirrung.

Tomasow sagte fast gütig: »Es ist schlecht von mir, daß ich Sie so überfalle, Ma --. Aber es hilft nun nichts mehr: bei Ihnen zu Hause bin ich mit Ihnen tausendmal weniger allein als hier, -- und im nächsten Augenblick stehn Sie wieder lächelnd und gewappnet da, -- in jeden Arm hineingeschmiegt eins Ihrer Kinder. -- -- Sie sollen mir auch nicht antworten müssen, Ma. Heute nicht und selbst morgen nicht, wenn Sie wollen. Nur wissen, -- wissen, daß Sie keineswegs so selbstherrlich allein dastehn werden, wie Sie wohl glauben, -- -- weil ich Sie mir nunmehr nehme --«

Marianne sah nicht auf. Die Röte auf ihren Wangen hatte sich vertieft, als ob sie wieder den Wind draußen um sich sausen fühle. Sie sprach sich innerlich die Worte vor, die sie Tomasow jetzt zweifellos sagen mußte, -- sie nahm sich vor, den Kopf zu heben und ihn einfach zu bitten, -- ja, zu bitten, er möchte doch wieder, ganz so wie bisher, gegen sie »gut« sein --.

Aber nach seiner Bemerkung, daß er keine Antwort erwarte, beugte sie den Kopf nur noch tiefer, und mit einem seltsamen Gefühl von Beklemmung erließ sie sich alles, um was sie bitten wollte.

Denn bei dem Ton seiner Stimme, da quoll langsam, unvermutet und betäubend eine wunderseltsame Gemütswallung in ihr auf -- --. Und machte sie zaudern, und ließ sie verwirrt den Blick Tomasows meiden, wie wenn eine geheime Sehnsucht etwas ganz andres ersehnt habe, als alle jemals bewußt gewordenen Gedanken in ihr.

-- -- Es war grade, als risse Tomasow mit ein paar gewaltsamen Griffen den Vorhang von irgend einer fremden Landschaft zurück, sodaß ihr plötzlich bewußt werden sollte: nur ein Vorhang scheide sie davon --.

Sie meinte noch nie durch diese Landschaft gewandelt zu sein und wußte doch auf einmal: nur ganz durchsichtig verhangen war sie ihr gewesen, und immer da war sie gewesen, dicht vor ihr. Und blitzschnell, zu neuem, verwirrendem Wiedererkennen, drängte sich plötzlich vor ihrem Auge Bild auf Bild daraus. Minuten, Momente aus ihrem Verkehr mit Tomasow sah sie vor sich, -- oft unterbrochen durch Monate und weit länger, oft einander rascher folgend in feinen, unmerklichen Sensationen, -- auf die sie mit dem Finger hätte weisen können: da -- und da -- und da, -- ja, war sie da seinen Wünschen nicht, ohne es zu wissen, ganz nah gewesen, -- ganz nah einem weiblichen, eignen Glücksverlangen --?

Marianne saß regungslos und noch immer im Bann der leichten Mattigkeit, die sie heute umfing. Allmählich vermischte sichs ihr ganz, wo und wozu sie sich hier befand, tief benommen von der Gemütsbewegung, die Macht über sie gewann. Sie fühlte sich wie jemand, der ganz unvermutet geweckt wird und in völlig irreführender Gegend zum Erwachen kommt. -- --

Tomasow war ebenfalls verstummt. Nur sein Blick ruhte immer wieder auf Marianne und mochte ihm einiges von dem enträtseln, was in ihr vorging.

Ohne daß sie miteinander sprachen, ohne daß sie einander auch nur anschauten, leitete sich zwischen ihnen eine Verwandlung ihres gegenseitigen Verhältnisses ein: das nahm er mit allen Nerven wahr. Und auch er überließ sich einem Hinträumen, das ihn weit fort entführte -- --.

Das Blut stieg ihm in die Schläfen, und seine Augen bekamen einen eigentümlichen starken Glanz.

Ganz still war es in dem kleinen heißen Zimmer. Ein einziges Mal ging draußen im Vorraum kreischend die Außenthür, ein paar schwere Tritte, kurze Frage und Antwort, Papierknistern, und wieder wurde alles still.

Die beiden Frauen am Fenster hatten sich erhoben, rückten ihre Kopftücher zurecht und gingen auf knarrenden Schuhen mit wortlosem Gruß hinaus.

Da blickte Marianne auf, fast verstört. Unmittelbar darauf erhob sie sich schon. Die dumpfe, schwere Ofenluft benahm ihr den Atem.

»-- Sie wollen gehn?« fragte Tomasow und half ihr in den Pelz. »-- Wollen Sie nichts weiter genießen?«

Marianne schüttelte stumm den Kopf. Sie schien zu meinen: jetzt an die freie Luft draußen gelangen, das hieße zugleich, den ganzen Bann und Druck abschütteln. Diese heiße Stubenschwüle war allein schuld --.

Tomasow zahlte, und sie entfernten sich. Der Ostwind blies ihnen auf der Straße scharf, förmlich wehethuend entgegen, er weckte fast ein Gefühl unwillkürlichen Sichbergenwollens.

»Wohin nun?« fragte Tomasow, »muß es schon heimwärts gehn?«

Marianne nickte zögernd.

»Den Kreml durchqueren,« meinte sie, »das ist wohl der nächste Weg.«

»-- Und wärs auch nicht der nächste! Denn allzu kurz darf er nicht geraten,« bemerkte er lächelnd.

Beim Ueberschreiten des Fahrdamms, zwischen den durcheinander sausenden Schlittengespannen, hatte er Marianne den Arm gegeben und führte sie mit der sichern Haltung dessen, bei dem sie sich von nun an bergen sollte. Oder empfand nur sie es so, als ob alles um eine Nuance verändert sei, als ob in allem schon eine stillschweigend anerkannte Zueinandergehörigkeit betont liege --.

Eben begann Tomasow Marianne von seiner Liebe zu reden, da traten sie schon in das Erlöserthor ein, das in den Kreml hineinführt. Die Fuhrwerke mäßigten den Schritt, die Menschen entblößten ihr Haupt, und Tomasow, der mechanisch seinen Hut abnahm, konnte in der um sie eingetretenen Stille nicht recht weitersprechen.

Dann kamen sie auf den weiten Platz hinaus, vorüber an den Kathedralen und dem alten Facettenpalast. Er schaute hin, und ihm fiel eine kleine Zeichnung von Rjepin zu dessen Gemälde »Die Brautwahl« ein, -- ja, so hätte er um Ma freien mögen: inmitten der Pracht der alten Palasträume, der niedrigen Wölbungen russischer Terems, als der alten Fürsten einer --. Und er dachte zurück: noch sein Großvater hatte sich seine Bäuerin vom Feld in die Hütte geführt, und die geschmückten Dorfmädchen tanzten zur Hochzeit. Ja, Hütte oder Palast, das war fast das gleiche: in beiden Fällen ward der Mann der Fürst, der Herr vor seinem Weibe, das von ihm sein Leben empfing.

Vor Tomasows unruhig umherblickenden Augen erhob sich der Uspenski-Dom in der energischen Schlichtheit seiner männlich gedrungenen Architektur, die grauen Kuppeln gleich Heldenhelmen auf Heldenhäuptern, ohne andern Schmuck, andre Farbe, als die verwitterten Bilder unter dem dunkeln Bleidach über dem Thor. Und davor, wie in sich selbst zusammengeschmiegt, in festlicher Anmut, die reizende Verkündigungskirche, die Vielkuppelige, die aussieht, als bildete die Gliederung ihrer Mauern nur eben soviele Vorwände, um eine stillleuchtende Kuppel nach der andern über sich emporzuhalten. Wie Weib und Mann standen die beiden in Tomasows Phantasie zusammen, die überall Symbole dessen schaute, wovon sie aufgeregt erfüllt war.

Den Kopf gesenkt, ging Marianne neben ihm, ihren Blick immer auf den flimmernden Schnee am Boden gerichtet, wie wenn sie mit geblendeten Augen was ablese von dem weißen Geglitzer mit seinen bläulichen huschenden Schatten und Lichtern.

Ihre Hand ruhte im Arm Tomasows; ein wenig zu ihr vorgebeugt, unterhielt er nun Marianne mit halber Stimme. Unruhevoll schweiften ihre Gedanken um das, was er zu ihr sprach. Kaum vermochte sie es aufzunehmen in den einzelnen Sätzen, in den verhaltenen Worten, so stark wirkte es seiner Grundbedeutung nach auf sie --. Ihr ward beklommen wie in der kleinen dumpfen Gaststube vorhin; die Schwüle blieb -- --.

Führte er sie nicht hinauf auf einen Berg und zeigte ihr der Welt Herrlichkeit, -- jene Herrlichkeit, die man zu eignem Genießen haben kann, in der man sich selbst leben kann, sich sättigen in allem Angenehmen und Erfreulichen des Daseins? Führte er sie nicht hinweg aus der Alltagsniederung mit ihrer einseitigen, bittern Mühsal, mit den armseligen paar Aufgaben, die ihre Kraft aufgesaugt, sie gedemütigt und unfähig gemacht hatten zu eigner, breiterer Entfaltung? -- -- Und wieder schaute sie bei Tomasows Worten wie in lockende Weiten, in eine Landschaft hinein, seltsam fremd, seltsam vertraut, in der sie sollte ausruhen dürfen an labendem Glück, sich gehn lassen in süßer Ermattung, -- und seine Stimme verhieß ihr fort und fort: wolle nur, und all dies ist dein --.

Sie überschritten grade den Platz, als ein erster tiefer Glockenklang mit überwältigender Gewalt die Luft durchhallte. Unmittelbar darauf setzte das Geläute von mehreren großen Glocken ein. Es that den Menschen kund, daß die Feierzeit nahe, daß sie das Werkzeug niederlegen möchten und die Seele öffnen, auf daß auch sie feiere.

Und in Mariannens Seele wiederhallte es in einer lauten Bejahung: sie sehnte sich, zu feiern --.

Aber gleichzeitig klangen mit den Glockenklängen ganz andre Stimmungen als zuvor in ihr an, sie kam heim von ihren ungewiß schweifenden Träumereien, zurück in die Gegenwart ihres wirklichen Lebens, und -- wie zwei, die sie gewaltsam hatte vergessen wollen, -- schauten ihr die Gesichter ihrer beiden Kinder fragend daraus entgegen --.

Fragend, -- so wie heute morgen: Sophiens Gesicht dabei ein wenig verschmitzt, voll pfiffiger Erwartung, beinahe wie sie auch als kleines Kind ausgesehen hatte, wenn die Heimlichkeiten um Weihnachten begannen. Citas Augen fragten nicht mehr kindlich: bringst du mir auch was Schönes mit? Sie hatte sorgenvoll vor sich hingeblickt, -- zweifelnd fast, -- sie war beunruhigt durch das Benehmen der Mutter. Und wenn sie jetzt erfuhr, -- Cita --

Mariannens Herz that plötzlich einen starken, harten Schlag. Sie blieb stehn, wie atemlos: wenn Cita erfuhr -- und auch Sophie -- --, sie sah mit einem Schlage die beiden Gesichter verwandelt, bestürzt, ungläubig --, sie fühlte mit unwiderleglicher Deutlichkeit: dann erst entfremdeten sich ihr die Kinder ganz --.

Alles Entfremden bisher bedeutete, dagegen gehalten, noch wenig, -- wie weh es auch thun mochte, es mußte machtlos bleiben, solange die Mutter selbst nur ihren Mädchen dieselbe blieb. Auch wenn sie Tausende von Meilen weit fort von ihr gingen: sie entfernten sich weniger weit, als durch einen einzigen Schritt, den sie selber fort von ihnen that.

»-- Die Kinder --!« sagte Marianne unwillkürlich, mitten in Tomasows Worte hinein, und sie hob zum erstenmal den Blick zu ihm, -- ratlos, hilfeheischend. War er doch da, ging er doch neben ihr, -- er, der immer alles entschieden, bei allem helfend eingegriffen hatte.

Voll Zuversicht schaute sie zu ihm auf.

»Was ist denn mit den Kindern?« fragte er etwas brüsk, aus der Stimmung gerissen; seine Augen begegneten den ihren mit eigentümlichem, flackerndem Leuchten, »-- es handelt sich jetzt doch gar nicht um die Kinder.«

Mariannens Blick glitt rasch, betroffen von ihm ab. Wer half ihr von nun an in allen Fragen und Kämpfen? Er nicht mehr! Er half ihr nicht mehr gegen ihre eignen Schwächen. Bisher konnte er sich ihr so geben, wie sie ihn brauchte, um sich als Mensch hoch und höher emporzuringen. Jetzt, ohne alle Zurückhaltung, brauchte er sie selbst, brauchte sie ohne die Kinder. Wie weit, -- weit standen ihm da ihre Herzenssorgen --!

Irgend etwas in Marianne, irgend ein eben erst entfachtes, eben erst wiedererwachtes Sehnen des Weibes in ihr verschüttete sich wieder und wollte zagend erlöschen --.

Tomasow fühlte sofort, daß er einen Fehler begangen habe.

»Alles hat seine Zeit!« sagte er schnell und bestimmt. »Auch die Kinder haben ihre Zeit gehabt, wo Sie sich ihnen ausschließlich widmeten. Nun ist es endlich Zeit geworden, in diesem Punkt vernünftig umzulernen. Schließlich muß man eben wählen, ob man einander leben will und dem Glück, oder ob man von ihrem unreifen Willen abhängen will.«

Und mit größerer Dringlichkeit als vorher sprach er auf sie ein, indessen sie weitergingen im hallenden Glockengeläut, vorbei an den weißgoldenen Mauern der zahllosen Kirchen und Kathedralen. Und je länger er redete, desto mehr wurde es eine Apotheose des sorglosen Feierns und Genießens, wozu er sie einlud. Er suchte alles hervor, was er ihr schenken könnte, und alles ward immer wieder Genuß und Fest. Aber Mariannens Hand lag nur ganz leicht in seinem Arm, sie stützte sich nicht mehr auf ihn, sie sah unruhig aus, und aus ihrem Gesicht war die gläubige Zuversicht geschwunden.

Und Tomasow überfiel plötzlich eine zornige, bittere Ungeduld wider alles, was er da selbst zu Marianne sprach. Alle die Worte von Glück und Freude erschienen ihm unwahr und schal. Er begriff plötzlich, daß er, an Mariannens Seite, doch immer nach einem suchen würde, nach eben dieser emporschauenden Zuversicht, nach eben dieser gläubigen Anlehnung an ihn, als an einen Stärkern, Ueberlegenen, -- an den Herrn. Glück mit ihr genießen, das konnte nur heißen: ihr im Leben selber so hoch und stark als Mensch überlegen sein, wie er ihrs in einzelnen Stunden durch Verstand und Rat gewesen war --.

Tomasow verstummte.

Und Marianne merkte es kaum. Wie sie so an seinem Arm hinging, schienen ihr jetzt die Glocken über ihr mit den weithin hallenden Feierklängen nicht mehr dieselbe Sprache zu sprechen, wie die dringliche Stimme dicht an ihrem Ohr, -- aus einer andern Welt schienen sie zu reden, als dies halblaute überredende Raunen von Feiertagsglück und abgeworfenen Sorgen --. Und immer mächtiger wurden die Glockenklänge und immer verhaltener die zuredende Stimme, und endlich vernahm sie nur noch Glocken, -- Glocken allein -- --.

»-- Leben Sie wohl, Ma!« hörte sie unvermittelt Tomasow sagen, der stehn blieb. »Ich habe Ihre Antwort schon, noch ehe Sie eine Antwort in Worten gefunden haben. Und lassen Sie mich bekennen: Sie haben recht --«

»Tomasow,« fiel Marianne tief bewegt ein, »-- warum wollen Sie so -- --! -- Sie sind immer und immer mein bester, einziger, liebster Freund --«

»-- Gewesen!« ergänzte er rasch mit einem unmerklichen Lächeln, und dann, sich umsehend, trat er zur Seite. Es kam jemand von hinten her an ihnen vorbei und zog grüßend den Hut.

Hugo Lanz war es, der desselben Weges ging und Marianne hocherfreut begrüßte. Marianne mußte ihn Tomasow vorstellen.

»Ich eilte grade zu Ihnen, gnädige Frau,« bemerkte Hugo Lanz, »um Ihnen eine für mich freudige Nachricht mitzuteilen --«

»Das trifft sich in der That gut,« meinte Tomasow etwas heiser, »daß ich mithin die gnädige Frau in Ihrer Begleitung lassen kann. Mein Weg führt hier leider nach andrer Richtung.«

Marianne reichte Tomasow die Hand, zögernd, fast zitternd.

»-- Aber doch auf Wiedersehen sehr bald --?« fragte sie mit nicht ganz beherrschter Stimme.

»Gewiß, gnädige Frau: sobald sich einmal gute Bekannte bei Ihnen versammeln, dann gestatten Sie mir vielleicht, auch dabei zu sein,« entgegnete er mit leichter Betonung dieser Antwort, beugte sich über ihre Hand, grüßte Hugo Lanz und entfernte sich, in die nächste Straße einbiegend.

Marianne ging statt vorwärts wieder zurück, ohne recht zu wissen und zu sehen, wo sie ging. Ein Angstgefühl umklammerte sie dumpf: sie konnte nicht fassen, daß das ein Abschied für das Leben gewesen war.

Sie machte eine gewaltsame Anstrengung, um sich Hugo Lanz zuzuwenden, dessen offnes Gesicht von Freude geleuchtet hatte, der aber jetzt ernst und still aussah, weil er sie so seltsam ernst vor sich hin gehn sah.

Er erzählte dennoch froh: »Soeben erst hab ich die Erlaubnis ausgewirkt, den nächsten Winter noch ganz frei zu bleiben, -- und ich werde ihn hier zubringen. Meine Verwandten haben mich aufgefordert, bei ihnen zu wohnen. Und schon die Aussicht, Sie und Ihre Familie besuchen zu dürfen --«

»Das freut mich innig,« bemerkte Marianne leise, »doch werden Sie im nächsten Winter nur noch mich wiederfinden, -- nicht mehr meine Töchter. Auch Sophie geht fort, folgt der Schwester ins Ausland.«

Hugo Lanz blickte Marianne mit aufrichtigem Schreck ins Gesicht. Die kleine Familienscene, der er beigewohnt hatte, stand vor ihm, Mariannens strahlendes Glück zwischen ihren Kindern, -- auch dessen, was ihm Sophie mitgeteilt hatte, entsann er sich.

»-- Ganz allein bleiben Sie --?« entfuhr es ihm voll Mitleid und in unwillkürlichem Unwillen.

Marianne wiederholte mechanisch: »-- Allein --,« und sie nickte bejahend. Aber das dumpfe Angstgefühl in ihr verstärkte sich dabei, als risse es sie mit jedem Schritt gewaltsamer hinein in etwas Endloses, Grenzenloses, -- wie in eine leere, gähnende Unermeßlichkeit, wo ihre Kinder und der Freund und alles, was ihr lieb gewesen war, alles Warme, alles Trostvolle, alles Hilfreiche, weiter und immer weiter zurückwich, -- unerkenntlich geworden schon, -- unaufhaltsam, unerreichbar -- --.

Und mit dunkelm Grauen stieg in ihrer Seele eine Erinnerung auf an abgrundtiefe Einsamkeit, aus der sie doch nur die Hand des Freundes und der Blick ihrer Kinder gerettet hatte, -- und sie fühlte, daß das dunkle Grauen nahe und näher über ihrer Seele zusammenschlug, -- als würde sie unbarmherzig dahinein gestoßen von derselben Hand, von denselben Blicken, die sie einst rettend festhielten, -- und als fände sie diesmal nie mehr, -- nie mehr hinaus --.

Marianne nahm nichts mehr deutlich wahr, die Dinge ringsum schienen ihr langsam zu entschwinden, sich in sich selbst aufzutrinken, unterzugehn in einem chaotischen Nebel. Einförmig nur und erschütternd laut hallten fort und fort die Glocken über ihr, -- hallten um sie, -- hallten in ihr, -- begruben sie wie unter einem Mantel von dröhnenden, besinnungraubenden Tonwellen, -- ließen alles an ihr erbeben unter der Gewalt des einen unerbittlichen Klanges, -- drangen auf ihre zitternde Schwäche ein, wie mit läutenden Unendlichkeiten -- --

Marianne war, einer Ohnmacht nahe, stehn geblieben und rang nach Atem.

Sie standen wieder dicht vor der Verkündigungskirche, an den Stufen, über denen sich die Eingangspforte erhebt. Hugo Lanz hatte einen Arm um Marianne gelegt und führte sie, sie vorsichtig stützend, hinauf bis in den Seitengang, wo längs den Fensterchen von gewelltem Glas eine Bank stand.

Dort ließ er Marianne niedersitzen und neigte sich, neben ihr stehn bleibend, mit besorgter Frage zu ihr.

Aber sie achtete nicht auf das, was er flüsternd fragte. Dicht vor ihr öffnete sich das blausilberne Portal in den innern Kirchenraum, auf der Seite, wo sie eben hereingetreten waren, blickte von der Thür ein großes dunkles Christusbild zu ihr nieder, die Züge kaum kenntlich, ein schwarzer Fleck, umhüllt und umkleidet von unendlichem Goldglanz. Sie starrte darauf hin, bis sie vor Thränen nichts mehr sah. Rätsel hinter Gold --.

Aber leise und wohlthuend legte sich die Dämmerung dieser Kirchenwände wie schützend um sie. Kaum glichen sie Wänden, bedeckt mit alten nachgedunkelten Malereien wie reiche alte Stoffe, sich niedrig wölbend und wellend, wie ein ungeheurer Mantel, der sich in schweren weichen Falten um den Betenden legt, ihn sanft bergend vor der Außenwelt --.

Sie hob beide Hände vor das Gesicht und beugte sich tief vor, ohne ein Wort zu sprechen. Schweigend verharrte sie lange so.

Hier und da kamen von draußen Menschen vorüber, meistens Leute aus dem Volk; leise auftretend mit ihrem groben Schuhwerk, schritten sie tiefer hinein in das Schiff der Kirche, das in feierlicher Dämmerung vor ihnen dalag, nur an wenigen Punkten schwach erhellt von vereinzelten Wachskerzen, die daraus hervorblinkten.

Hugo Lanz stand neben Marianne, an ihre Bank gelehnt, und blickte auf sie nieder. Er wußte nicht, was in ihr vorgehn mochte, aber daß in dieser Stille etwas Erschütterndes in ihrer Seele zum Austrag kam, das mußte er wohl fühlen -- --. Und wenn er einst zu ihr gekommen war im drängenden Verlangen, an ihrer warmen Mütterlichkeit getrost und froh zu werden wie ein Kind, so wuchs jetzt eine Sehnsucht in ihm empor, -- groß, wie er sie nie gekannt hatte, -- stark zu werden und kraftvoll, ein Mann, um beschützen und behüten zu dürfen --.

Er stand da und horchte stumm auf das Geläute der Glocken, -- auf den seltsam packenden Klang dieser russischen Glocken, die sich weigern, sich mit ihren Klängen mitzuwiegen, und ehern feststehn, daß der Klöppel in ihnen anschlägt wie ein weithin tönender Befehl -- --.

Da ließ Marianne die Hände von ihrem Gesicht sinken und erhob sich ganz langsam. Hugo Lanz machte eine Bewegung zu ihr hin, aber die Andacht in ihren Augen und in ihrer ganzen Haltung bannte ihn. Es war wie eine unsichtbare Einsamkeit und Hoheit um sie, die er nicht zu entweihen wagte. Und unwillkürlich trat er zur Seite.

Einen Augenblick lang stand Marianne da, sich besinnend, fast schüchtern, mit einer sanften Neigung des Kopfes, die etwas Rührendes für ihn hatte, etwas von unaussprechlicher Ergebung. Aber auf ihren Zügen lag ein ruhiger Glanz, alle Angst war von ihnen gewichen.

Sie machte eine Wendung, um aus dem Portal hinauszutreten, ohne ihren Begleiter zu bemerken. In diesen Minuten hatte sie auch ihn vergessen. Er schaute ihr nach, und unwiderleglich kam ihm das Gefühl: -- als ginge sie gar nicht allein -- --.

Ein paar Schritte hinter ihr trat er hinaus auf den Platz.

Unten in der Stadt, die dem Kreml zu Füßen lag, blinkten eben die ersten Lichter auf. Schon war es nicht mehr ganz hell. Weißlicher Winternebel zog sich in der Ferne über die Ufer des Flusses. Fest um den Kreml geschmiegt, standen die Häuser da, rot und blau und grün an Dächern oder Mauerwerk, und erwarteten nach des Tages Treiben das Dunkel, durch das das siegende Gold der zahllosen Kuppeln hindurchschien wie eine ewige Leuchte, die nicht mit dem Tage erlischt.

Ein unerhörtes Abendrot stand über Moskau. Und die Buntheit der Farben ringsum nahm auch noch den schwächsten Abglanz davon, nahm auch den leisesten Funken so innig auf, hielt sich ihm an der Oberfläche aller Dinge als ein so williges Gefäß entgegen, daß es fast wirkte wie ein Lobgesang, der emporstieg von der Erde zum erglühenden Himmel. Eine Stimmung wie ein Ausgleich zwischen Freude und Gebet lag über dem Ganzen. Die paar Wolken, die inmitten der Bläue des Himmels zögernd dunkelten, zogen sich, lichtdurchschossen, langsam zu breitschimmernden Goldbändern auseinander -- --.

Da ging ein flüchtiger Regenschauer nieder, warm und ganz kurz, wie ein Thränensturz.

Hugo Lanz blieb stehn und schaute hinab, dorthin wo Mas feine ruhige Gestalt im Abstieg zu den Anlagen sichtbar blieb.

Wie klein und unscheinbar verschwand sie dort zwischen den Bäumen. Und ihm schien doch alles ringsum sie allein zu feiern und zu umstrahlen --.

Denn in ihm arbeitete sich irgend ein Bild mit mächtiger Gewalt zu künstlerischer Klarheit hindurch, -- ein Bild, in dem er Ma vor sich sah, -- ein Bild, in dem ihr Glück lebte und ihr Vereinsamen, und ihr Weh, und ihr Sieg, -- ein Bild, in dem geheimnisvoll lebte, was in diesem Augenblick in ihr selbst wohl nur in dunkeln Ahnungen rang -- --.

Und es kam ihm vor, als stünde er angesichts eines großen Schauspiels, um deswillen man das Leben fürchten und lieben lernen mag. Und das den Schauenden, dem es seine Heimlichkeit enthüllt, zum Kinde werden lassen mag, und zum Manne, -- und zum Dichter.

-- Ganz benommen und wie sich selbst entrückt, blickte er hinab von der Kremlhöhe in die Tiefe der Stadt.

So sah er Ma schweigend, still niedersteigen unter dem verhallenden Geläute der Glocken, -- einen von oben in die Wohnungen der Menschen entsendeten guten Geist.

Read this book from cover to cover before you start your project.

Your guide for the project

Learn to sew—have fun. This book will help you get the right start on your second 4-H clothing project. Read it carefully and study the pictures. Ask your mother to read and study with you. Follow the instructions and you will form good habits. This project is planned for you. Learn to do each part step by step.

Keep this book in your sewing box. Refer to it whenever you need help.

Study these subjects

1. Care of clothing— sew on buttons shine your shoes keep dresses on hangers in closets or placed neatly in drawers 2. Good grooming— keep neat and tidy practice good health habits 3. Cotton fabrics 4. Use of your sewing machine

Articles to make

One of the following first for practice Head scarf—single Head scarf—double Sewing kit TV slippers An apron or skirt as your main project Gathered skirt Peasant apron Elastic top apron Cover-all apron

Add to your record book

Your County extension agent will give you your 4-H record sheets. Keep your clothing record up to date. Write your 4-H story for the year when you complete your project. Be sure to fill in your permanent record, too. There are places on your permanent record to show the activities you have participated in—be sure to keep a record of them. Activities plus project work make a well-rounded 4-H program.

Learn to give a demonstration

Show others what you have learned by giving a demonstration at one of your club meetings. When you show another club member how to tie a knot or sew on a button, you are giving a “demonstration.” Things that are done or seen are remembered longest. Give your demonstration alone or with a partner. You will find demonstrations interesting and helpful. Ask your leader to give you ideas on how to give a demonstration. Choose a topic you have studied in your project.

Plan your project

You will want to talk about your project with your mother and leader. This will help you to understand your project. Study the project outline and your record book. Take your mother with you to your first 4-H club meeting.

You will need your mother's cooperation in selecting equipment and cloth.

Plan to do all your shopping at one time. Buy the cloth for your apron or skirt and slippers or scarf at the time you buy your sewing equipment. This will save you time.

Before you go shopping make a list of all of the things you will need. Think about the blouses or dresses you have when you plan the colors for your skirt or apron. You may want to wear your scarf and skirt together—if you do, plan the colors to go together.

This project is more than just sewing. You will study health and good grooming and how to care for your clothes.

Get off to a good start by learning how to care for your shoes and how to sew on buttons.

Take care of your clothing

Shine your shoes

Daily care will improve the looks of your shoes and will help make them wear longer. Clean and polish your shoes. Wipe them off with a clean (wool) cloth and brush away the loose dirt before you put them away. When they need polishing, use one of the many good polishes that are on the market. Select the kind that is best for the leather in your shoes. Follow the directions given with the polish.

[Illustration: Shoe]

Shoes become damp from perspiration when you wear them. Wearing socks will protect the lining. Allow your shoes to dry thoroughly between wearings. Filling the toes of your shoes with tissue paper will help absorb the moisture.

Examine your shoes for signs of wear. Keep the heels straight and do not wear the sole through before having it repaired. Have all rips mended as soon as they appear.

Do not place wet shoes near heat or in the sun to dry. When they are dry, clean and polish them to make them look like new.

Your dress is only as pretty as the shoes you wear with it. Are you proud of the care you give your shoes? Keep a record of the care you give your shoes in your record book.

Sew on buttons

To help mother care for the family clothing, why don't you take the responsibility of replacing buttons on shirts and blouses for the family. Make a game of it with other members of your club. Have a button contest. Give yourself a point for each button you sew on. The club could plan to give a prize to the girl who sews on the most buttons during the club year.

Keep a record of the buttons you sew on, something like this:

Date	Article of clothing	Points—or number of buttons
_____	_____	_____
_____	_____	_____
_____	_____	_____

Record the total in your record book.

Use buttons to trim your bedroom slippers. Select one flat, medium-sized one or three small ones. Arrange them on the toes of your slippers to make an attractive trim.

How to sew on a button

1. Make a small knot in double thread (15 inches long). Fasten to article where center of the button is to be placed. Take two or three stitches over the knot.

2. Sew the button in place with one or two stitches. See that the stitches run in the same direction as the buttonhole.

[Illustration: Sewing on a button]

3. Place a pin on top of buttons under the first stitches. This makes a shank. Continue to sew on the button. Take as many stitches as necessary to hold the button securely. When the stitches are in place, remove the pin. Lift the button away from the article. Wind the thread tightly around the stitches, as shown, and fasten the thread on the back by taking three or four stitches, one on top of the other.

Assemble your sewing tools

You will need a sewing box or basket and good sewing tools. Obtain a small box to hold your tools and another one large enough to hold your small box plus your apron or skirt. A small suitcase makes an ideal sewing box.

[Illustration: Sewing tools]

You will need

Thimble—This is for the middle finger. Make sure of a snug fit. A thimble protects your finger.

Needles—A package of needles, assorted sizes of 7 to 9 sharps, will give you the various sizes needed. Use as fine a needle as will carry the thread you are using.

Thread—White mercerized thread No. 50 is used for basting. Match other thread to your fabric.

Pins—Select smooth fine dressmaker pins so they will not leave a dark spot on your cloth. These usually come in a box.

Pin cushion—Plan for a pin cushion that can be worn on the wrist. You may make or buy this.

Scissors and shears—Scissors have short blades and are used for snipping threads and cutting small pieces of material. Seven-inch blades are a good length. Shears have one long handle for the fingers and one short one for the thumb. Scissors with bent handles are handy because the cutting blade rests flat on the table. Use plain scissors to cut out your articles. Do not use pinking shears.

Tape measure—Select a tape measure that will wear well and one that is numbered with “1” on each end on opposite sides.

Measuring gauge—You can cut a gauge from cardboard or buy a 4-inch metal one. From the start, learn to measure accurately. On a tape or measuring gauge, locate the 1-inch, ½-inch, and ¼-inch marks.

Do your shopping

Buying cotton fabric

When you start to sew, it is most important that you have a fine, firm piece of cotton cloth. The best fabric for your scarf, skirt, or apron is percale, either plain or crease resistant. Percale is soft and firm, and comes in figured and plain colors. Select a small all-over pattern in colors that you will enjoy wearing. Avoid plain colors, plaids, or large designs. Also avoid cloth which feels stiff. Crush several pieces of cloth in your hand. You will be able to tell the difference. Select the one that wrinkles the least.

When you buy your fabric, be sure it is preshrunk and colorfast. Also find out if it is crease-resistant and how to wash it. Is it hand washable or machine washable? You will find most of this information on the end of the bolt of fabric or on attached labels. Study these and also ask the clerk to tell you about the fabrics.

[Illustration: Bolt of fabric]

WASH & WEAR LITTLE or NO IRONING MACHINE WASH—DRIP DRY CREASE RESISTANT

Cotton/Arnell coordinates

55% Cotton 45% Arnell Tri-Acetate

WIDTH 44/5″ COLOR_____ YDS._____

Good percale has the same number of threads in the warp as in the filling. The warp threads are those that run the long way of the fabric. The filling threads go back and forth across the warp threads. The filling threads are softer than the warp threads but not as strong. Examine the edge of the fabric. The edge is called selvage. It is stronger than the rest of the cloth because it has more threads in it. This may also cause it to shrink more during washing.

[Illustration: Selvedge]

Percales should be torn, not cut, from the bolt. This leaves a straight line or shows one thread for the entire width of the cloth. Before you buy any fabric, lay the folded cloth on the counter and examine the torn end. Are both sides even or is one side an inch or so shorter than the other? Select a piece which is reasonably even. Do not select fabric if one side is more than ½-inch shorter.

Border prints make interesting skirts. Study the design on the cloth and buy enough cloth so you can match the design on the side seam. Make sure the fabric is straight. Crooked fabric will give you a curved side seam.

[Illustration: I KNOW THESE FABRICS—DO YOU?]

Percale may be used for all the articles you will make in this year's project. Other fabrics that may be used are chambray, broadcloth, poplin, and novelty fabrics.

Plan a shopping tour with your club before buying your fabric. After studying the different cotton fabrics, have your leader and mother help you select the fabric for your scarf, apron, or skirt. If you plan to make a double scarf, buy ½ yard additional fabric like your skirt and the same amount of a contrasting color.

You will need two washcloths if you plan to make the TV slippers. Select medium weight washcloths either with or without border trim.

Learn to use the sewing machine

Many of you learned to use the sewing machine in Phase 1 of _It's Fun to Sew_. You will find this section of your bulletin to be a good review.

For those of you who are starting with this phase, this section will help you become acquainted with the parts of the machine and will tell you how to use it.

The needle—Notice that it has an eye near the point instead of at the top like the one you use for hand sewing.

The presser foot—See the two toes between which the needle passes? This is the presser foot. Find the small metal arm which raises the presser foot up and down. The metal arm is on the back of the machine.

The bobbin—This carries the thread for the underside of the sewing. Bobbins are different shapes and sizes for different machines. Learn to place the bobbin in the machine and to remove it. Learn to wind the bobbin.

The balance wheel—This is the wheel on the right-hand side of the machine.

When you can recognize these parts and know their use, you are ready to learn to run the machine. Check these points before you start to use the machine:

1. Remove the bobbin and top thread.

2. Have the needle up as far as it will go.

3. Raise the presser foot.

How to start the machine

You are now ready to get the "feel" of running the sewing machine. You will first practice starting the machine off slowly and evenly.

If you use an electric machine, you must learn how much pressure to put on the knee or foot control. Remember there is a lot of power in an electric machine.

If you use a treadle machine, put both feet on the treadle, one ahead of the other. With your right hand, move the balance wheel forward or back, whichever is right for your kind of machine. Take your hand off the balance wheel and treadle with your feet, pressing first with your toes and then with your heels. Practice treadling until you can run it smoothly at a moderate speed.

[Illustration: Sewing.]

How to stop the machine

Try stopping the machine by slowing down the treadling or releasing the pressure on the electric control. With your right hand, stop the balance wheel. Turn the wheel slowly until the needle is raised as high as it will go. Always do this when you stop the machine. Practice starting and stopping. You will do this many times while you are sewing. Try stitching both forward and backward if there is a reverse lever on your machine.

Practice sewing on paper

Now that you can run the machine, practice sewing by first stitching on paper. Draw some straight and curved lines on paper as a guide to follow as you stitch. Here is how to do it:

Place the end of a line under the needle.

Lower the presser foot. This holds the paper securely and helps feed it through the machine.

Start the machine by turning the balance wheel. Treadle slowly or press on the foot or knee release of the electric machine.

Guide the paper with both hands. Place the left hand in back of the needle and the right in front of the needle. Keep your hands at a safe distance from the needle when stitching.

When you can stitch straight and control the speed of the machine, you are ready to learn to thread the machine and start sewing an easy-to-make article.

Thread the machine

You can best learn to thread the machine by having your leader show you how to thread it. Then practice while she watches you. Watch closely when she draws the bobbin thread to the top and see how she pulls both threads back of the presser foot. Learn about the tension. The tension determines whether or not you have a good stitch. Until you are older, have your leader or mother adjust the tension for you. Watch her while she does it.

Check the stitch

Pull both top and bobbin threads back of the presser foot. Place a double thickness of cloth under the presser foot and make several inches of stitching. Inspect the stitch. Does it look the same on both sides? If not, have the tension adjusted until it does.

Use 12 stitches to the inch for the type of sewing you will be doing. Have your leader show you how to adjust the length of the stitch.

When you have finished sewing, raise the needle as far as it will go. Raise the presser foot and pull the fabric back about 4 inches from the needle. Cut the thread with your scissors or on the cutting knife on the side of the needle-bar.

[Illustration: Sewing machine needle]

Use a cloth gauge

A cloth gauge placed to the right of the needle will aid you in making straight seams. Place a strip of colored scotch tape, band aid, or adhesive tape to the right of the needle if you do not have a gauge. Watch the edge of your cloth as it follows along the gauge rather than watching the needle when stitching. This will help you make a straighter seam.

Your posture at the machine

Posture is important. If you sit “tall,” you will be less tired and will do better work.

Become a 4-H machinist

There is a special activity planned to help you learn how to use the sewing machine. It is called “Know Your Sewing Machine.” Ask your leader and county home agent about this.

Learning to use the machine is the most important part of this clothing project and it is a lot of fun. Bring your mother to club with you the day you study machines so she can enjoy it with you. When you have learned to use the machine and can pass your test for a 4-H sewing machinist, your leader will sign your certificate. You are now ready to start to sew.

Have you learned to:

[_] Start and stop the machine? [_] Run the machine smoothly? [_] Wind the bobbin and place it in its case or shuttle? [_] Thread the machine, top and bobbin, and pull up the bobbin thread? [_] Adjust the length of stitch? [_] Stitch on straight lines, corners, and curves? [_] Guide, not force, the fabric? [_] Tell a good stitch?

Learn to press cotton

Examine the iron—locate the different parts. Set the heat indicator of your iron for cotton. This will keep the iron at the correct temperature.

Cotton may be ironed on either the right or the wrong side. If your fabric does not iron out smoothly or take a sharp crease, dampen it. Here is how to do it:

Dampen a piece of cheesecloth and squeeze it tight. Do not make it wet. Place it over the cloth you want to press and set iron on it. Steam will form and dampen the cloth.

Always iron or press with the grain of the cloth. Follow the warp or the filling threads. Do not iron on the bias.

[Illustration: STRAIGHT and BIAS]

Sew—have fun

Now that you have practiced using the sewing machine, you are ready to make a scarf, slippers, or sewing kit.

Make a scarf

[Illustration: Wearing a scarf]

This scarf may be made larger than the measurements suggested but it will require more fabric. Using these measurements, a square of cloth can be cut into four scarves. It will be more economical to cut a scarf this way if four in your club use the same colored fabric.

Plan to have your scarf match or look nice with your skirt. For a double scarf, have one side the same as your skirt fabric and one a plain or contrasting color. A single scarf may either match your skirt or be a contrasting color.

Double scarf

[Illustration: Scarf Pattern]

Cut two triangles of fabric—

1—plain 1—contrast

Pin right sides together and sew a ½-inch seam around edge.

Start sewing 6 inches from center of scarf. Stitch around scarf and stop 3 inches before reaching starting point (see diagram). The opening is for turning your scarf.

[Illustration: Scarf seam]

Press the seams open. Then trim the seams until they are ¼-inch wide. Trim off corners. Turn your scarf and press.

[Illustration: Hemmed scarf]

Baste a slot for headband, 14 inches long and ¾ inch wide. Sew across one end. Turn and stitch along basting threads. Turn and stitch across other end. See diagram.

[Illustration: Scarf and headband]

Sew (by hand) 2 inches of opening, leaving 1 inch open to insert head band.

Insert head band and your scarf is finished.

Single scarf

Cut one triangle of fabric.

[Illustration: Scarf pattern]

Press ¼-inch hem on both 25-inch sides of scarf. Press ¾-inch hem on long edge of scarf.

[Illustration: Hemmed scarf]

Trim off end of hem on dotted lines. Turn ends under even with side hems. Press.

[Illustration: Folds in cloth]

Miter corner on point of scarf according to directions under sewing kit.

[Illustration: Mitered corners]

Refold the scarf on folds for hem. You now have a mitered corner.

[Illustration: Stitched scarf]

Stitch around your scarf. Start stitching 6 inches from center on 35-inch side. Stitch all around scarf.

Stop 1 inch from where you started to stitch. Turn and stitch to folded edge of hem. Stitch across hem 7 inches from center of scarf to make other end of slot to hold head band. Finish two top corners by hand. Trim off peak (x) to edge of hem. Insert head band and your scarf is finished.

Make a sewing kit

[Illustration: Sewing kit pattern]

This kit can be used to roll your sewing in and to cover your work table to protect your fabric while you are sewing.

[Illustration: Hems]

Use a 36-inch square of muslin. Make a ¼-inch hem on all sides.

To make the hem, turn the edge of the fabric over ¼ inch and press. Turn this over once again and press. Pin or baste around the hem. Pressing eliminates many hours of basting.

Miter the corners. Open the corners and fold along diagonal dotted line as shown in the diagram. Refold the hem and press.

Start to stitch in the center of one side and continue to stitch all around the square. Stitch as near the edge of the hem as possible. Remove your sewing kit from the machine when you finish stitching and tie ends of the threads. Pull out the basting and press your sewing kit. Trim off the extra fabric in each corner.

Place an 8 x 12-inch pocket in the center of this square to hold your pattern and sewing equipment. See “Pockets,” page 12.

Make TV or lounging slippers

[Illustration: Slippers]

Materials needed:

2 washcloths thread to match 2 10-inch pieces of ¼-inch elastic wool yarn for pompons or flat buttons

1. Fold each cloth in half. If there is a design on two sides, fold the cloth so the design is at the top. Stitch 4 inches from folded edge for top. Make a ¼-inch seam.

[Illustration: Folded sewing kit]

Stitch from fold to edge of cloth for heel on other end of washcloth. Stand on a ruler and measure length of your foot. Add 1½ inches to this length to get the size needed for your slipper. Example: foot—9 inches, plus 1½ inches equal 10½ inches. Your seam will be at this point. Most washcloths are 12 inches square. You would have a heel seam 1½ inches wide.

2. Turn seams to inside. Open the heel seam.

3. Fold the edges over 2 inches to the outside of the slipper. Pin or paste in place. Stitch ½ inch from folded edge to make a casing for the elastic. Tie or back tack ends of thread.

[Illustration: Casing for elastic]

4. Thread elastic through casing. Use medium-size safety pin. Pin to one end of elastic and thread elastic through casing. Start at opening of front toe. Pull both ends so they extend out from slipper. Overlap ends ½ inch and sew them together.

[Illustration: Threading elastic]

Pull on heel and toe seam and the slippers will cover the elastic. Trim your slippers with pompons or buttons.

[Illustration: Making pompons]

5. To make the pompons, use a four-tined table fork. Cut a piece of yarn about 6 inches long and place through the center tine of the fork. Bring both ends down and hold next to the handle. Now wrap the yarn around the tines, either weave it in and out of the tines or wrap smoothly around. When the tines are completely covered, bring the two ends which you are holding with the handle up around the other yarn and tie a knot, at the same time slipping the yarn from the fork. Tie securely. Clip through looped ends and fluff into a ball.

Sew pompons to center front of slipper to cover opening for elastic.

You may use buttons to trim your slippers instead of the pompons. Select flat buttons that can be washed. Use one average or large button or three small ones on each toe. (See “How to sew on a button,” page 2.)

Select yarn or buttons that will look nice on your slippers. They may be the same color as the slippers or another color that will look good on them. Try several colors. Medium colored buttons rather than black or other dark colors look best on pale colored slippers.

Make your apron or skirt

[Illustration: Aprons and skirt]

Aprons and skirts are fun and easy to make. This will probably be the first apron or skirt you have ever made all by yourself. Your leader will show you how to make it, step by step. Follow her instructions and you will learn to sew in no time at all. Learn to do each step right the first time.

Choose one that you would like to make

1. Peasant-type skirt

2. Peasant apron with straight band

3. Peasant apron with elastic top

Plan to have one or two pockets on your apron or skirt.

Peasant apron with band

You will need to buy:

30 inches of 39-inch percale or other firm cotton fabric—if you are taller you will need more material to make your apron longer. 1 spool of matching thread

[Illustration: Apron pattern]

SELVAGE APRON 20 × 32½ 5 × 32½ SASHES 5 × 32½ SELVAGE 6½ × 18 BAND POCKETS 5 × 6½ 5 × 6½

Measure and cut your apron

Mark the apron according to the diagram.

Band 6½ x 18 inches Apron skirt 20 x 32½ inches Two sashes 32½ x 5 inches One or two pockets 6½ x 5 inches

Measure and mark off these pieces with chalk or pins before cutting. Cut with long, even strokes.

Make your sashes

Fold the right sides of each sash together. Place pins across the stitching lines as shown in the diagram. Make a ¼-inch seam along the side and end of the sash. Backstitch for two or three stitches to make the end of your thread secure. Trim off the corner.

Check the stitch on your machine. Be sure it looks the same on both sides of the fabric.

[Illustration: Stitched sash]

Press the seam open and turn the sash. Use the end of a table knife or ruler for turning. Press the sash flat, keeping the seam at the edge. Make the corners square.

If you prefer to hem the sash, make a ¼-inch hem, miter the corners. See instructions on scarf, pages 7 and 8.

Press and stitch hems

Side hems

1. Make a ¼-inch hem on each side of the apron. To make a hem, press a ¼-inch fold on the side edges of your apron (20-inch sides). Press with your fingers, then with the iron.

[Illustration: First turn]

2. Fold edge over again ¼ inch and press. Stitch along edge of hem. This completes the hem.

Selvage edge—If the selvage is used, clip only the very edge of it every 2 or 3 inches. This prevents puckering when it is laundered. Fold the edge over ¼ inch, press and stitch. A double hem is not needed.

Bottom hem

Make a 3-inch hem on the bottom of your apron. Measure and turn ¼-inch fold at bottom of apron. Press. From this edge measure 3 inches, fold, and press. Pin and stitch the hems. Use matching thread. Stitch as near as you can to the edge of the hem. Backstitch on both ends of hem.

Gather the top edge

Divide the top edge of your skirt into four equal parts.

Set your cloth guide for a ¼-inch seam. Lengthen your stitch to make the largest stitch possible.

Make three rows of stitching along the top of the apron, placing rows ¼ inch apart. Place the first row ¼ inch from the edge. Be sure to follow the guide.

[Illustration: Gathered top edge]

Make your apron band

Your apron band is made the same way as a skirt band, only the proportions are different. Turn to page 14 for illustrations.

1. Press a ½-inch fold along one side of your 18-inch band. Divide the band, lengthwise into three equal parts. This gives three 2-inch sections. Make the section with the ½-inch fold slightly shorter than the other two sections. Place a damp press cloth over the folded band and press sharp creases along the folds.

2. The section with the ½-inch fold is the front of your band. The double part is the back. Stitch criss-cross through the back part of the band. You can stitch straighter if you make a guide or pattern. Cut a strip of waxed paper the length and width of your band, 18 x 2 inches.

Fold in four equal sections.

Then fold it diagonally. Then diagonally again. Open the paper and pin it to the band and follow the creases in the paper. This will give practice on starting and stopping the machine and on turning corners. Tear the paper away after the stitching is completed.

[Illustration: Apron band]

3. Pin and sew the end of the sashes to the end of the band. Fold the band right sides together, and stitch across ends. Do not sew the ½-inch fold at bottom of band into the seam.

[Illustration: Apron band]

Stitch both sides. Turn and press along the original crease.

[Illustration: Band on apron]

Sew apron to band

Be sure the edges of the band and apron are marked in four equal parts. Place the right side of the apron to the right side of the band. Match the quarter marks and pin. Place the hemmed ends of the apron at the seam ends of the band. Ease in the fullness in the apron until it fits the band. Pull all bobbin threads from each end at the same time. Pull gently so you do not break the threads. Spread the gathers so they are even and pin. Baste along the second row of gathering and the crease in the band. Machine stitch along the bastings. Press.

Pin so back edge of band is ■ inch longer than edge of front of band. Top stitch along front edge of band. This finishes your band. Be sure to press the band before you stitch. It will make stitching easier.

Add your pockets

Pockets are for both use and decoration. Make patch pockets that are securely stitched and have no raw edges at the top.

Press the side and bottom hems of the pocket first. Then fold the top hem over and stitch in place. Study the most convenient location for your pocket. Baste it in place. Check to see that it is even. Reinforce the top of the pocket with double stitching, as shown in the drawing. Stitching is ¼ inch apart.

[Illustration: Pockets]

Remove gathering stitches and press your apron.

[Illustration: Finished apron]

Peasant apron with elastic top

You will need to buy

30 inches of cotton fabric 1 spool of matching thread 14 inches of ½-inch elastic

Measure and cut your apron

Cut your apron 20 x 31 inches. This will fit a girl of size 10 to 12. Make this longer than 20 inches if you are tall.

Cut two sashes 26 x 5 inches.

Cut two pockets 5 x 5 inches.

Make sashes and hems the same as for peasant apron with band, page 10.

[Illustration: Apron pattern]

31 in. 20in. APRON 5in. 26 in. Pocket 5in. 5in. SASHES Pocket 5in.

Make the side hems ¼ inch wide and the top and bottom hems 2 inches wide.

Gather the top

1. Make a heading or hem at the top of your apron. From the top edge of the apron, measure down ¾ inch and mark with pins or chalk. Start stitching at upper corner and slope to ¾-inch line. Stitch across the apron and slope up to the corner.

[Illustration: Hemmed apron]

2. Stitch one sash to end of ½-inch elastic. Thread elastic through heading. Then stitch other sash to end of elastic. Pull ends of sashes into heading of apron.

[Illustration: Elastic hem]

3. Finish ends of bottom hem with a slip or blind stitch.

The slip stitch is used on a hem with a folded edge.

Fasten the knotted thread in the fold of the hem. Slip the needle through the fold for about ½ inch. Pick up one thread in the skirt or, if the fabric permits, split a thread with the needle. This thread should lie at right angles to the hem edge. Slip the needle back into the fold of the fabric, and continue hemming. Stitches are almost as invisible on the wrong side as the right side of the skirt.

[Illustration: SLIP STITCH]

Gathered skirt

Select fabric that is colorful and gay for your skirt. Closely woven cloth will be easy to sew and will hold a sharp crease.

You will need from 3 to 3½ yards of fabric for your skirt. The more fabric you try to gather in your skirt the harder it will be to make. For the girl of average height cut your skirt as follows:

How to cut your skirt

Cut or tear a 6½-inch strip from one side of your skirt fabric. Measure in from the selvage edge. Use this for the skirt band and pockets. There will be some left over.

Tear off the selvage edge from the large piece.

[Illustration: Skirt pattern]

6½″ SELVAGE BAND POCKET POCKET CUT OR TEAR SELVAGE

You may have to cut the band from the end of your fabric instead of the side if you are tall and need the extra length.

The above method of cutting gives you one seam on the placket side.

Sometimes the design in the fabric will be more attractive if the skirt is cut in several lengths. When this is necessary, you will have three or four seams in your skirt. This may make a difference in the amount of fabric you will need, so decide how you will cut your skirt before buying your fabric.

Make your skirt

Pin the short edges together to make the side seam. Make the seam 1¼ inches wide. It is to be used for the placket. When finished, the placket will be on the left side.

Stitch the side seam. Stitch the seam from the bottom up. At a point 5 inches from the top, turn and stitch half way across the seam. Turn both edges of the seam toward the front section and press.

[Illustration: Stitched seam]

Trim the seams. Start at the bottom of the wide seam and trim it to ■ inch wide up to the placket. Do not trim above this point.

[Illustration: Trimmed seam]

Finish the placket

1. Baste and stitch a ½-inch hem on the back edge of the placket.

[Illustration: Hem on placket]

2. Fold the front edge of the placket even with seam line. Press. Now fold again to make a complete hem. Baste.

[Illustration: Pinned placket]

Pin placket together. Stitch from the top to the bottom of the placket, turn and stitch across the end of first stitching. Pull threads through and tie ends. This is a strong, easy-to-make placket.

[Illustration: Stitched placket]

Hem the skirt

Skirts look best with hand-stitched hems. Make the hem before placing the band on the skirt. Unless you have poor posture, it will hang even. Decide how long you would like your finished skirt to be. Be careful not to make it too short. Measure from the top edge to the length you would like the skirt to be and press in the hem. Turn the top edge of the hem under ½ inch. Your skirt will be prettier if you make a wide hem—3 inches or wider.

When the hem has been carefully pressed, stitch ■ inch from the fold of the top edge of the hem, to keep the fold in place. Pin hem in place. Ask your leader to show you a hand hemming stitch.

Place gathering threads at top of skirt

Make a long stitch on your machine. Use size 50 top thread and heavy duty for bobbin thread.

Using the guide on your machine, stitch around the top of your skirt ¼ inch from the edge. Make two more rows ¼ inch apart. You are now ready to make your skirt band.

[Illustration: Gathering treads]

Make the skirt band

1. Measure your waist. Add 2½ inches. This will give you the length needed for your skirt band. Cut your band 6½ inches wide.

2. Press a ½-inch fold along one side of your band. From the folded edge divide the rest into three sections. This gives three 2-inch sections. Make the section with the ½-inch fold slightly shorter than the other two sections. Press.

3. The section with the ½-inch fold is the front of your band. Stitch criss-cross through the back part of the band. You can stitch straighter if you make a guide or pattern. Cut a strip of waxed paper the length and width of your band, 24 x 2 inches.

[Illustration: Cross-stitched band]

Fold it in six equal sections. Then fold it diagonally. Then diagonally again. Open the paper and pin it to the band and follow the creases in the paper. This will give practice on starting and stopping the machine and on turning corners. Tear the paper away after the stitching is completed.

[Illustration: Folded paper for band]

4. Stitch a ½-inch seam at the ends of the band. Turn and press. Do not sew the ½-inch fold at the bottom of band into the seam.

Gather in fullness

Divide both your skirt and the skirt band into eight equal parts to help you make the gathers even in your skirt. Do not include the placket or 1-inch overlap at the end of the band. Mark with colored threads. Mark the skirt band so the extension or extra length will be on the back of the placket. The front of band will be even with the front edge of the placket.

Pin and stitch band to skirt.

Pin the pieces together, right side of skirt to right side of band. Match dividing marks that you have made. Gently pull on the gathering threads at the side seams, the center front, and the center back. Pull the threads until they are the same length as the band. Work with the gathers until they are even. Baste and stitch along ½-inch fold on the skirt band.

Top stitch the band

Fold the double section of your band toward the back and baste the edge of the band to the skirt. Baste it so the folded edge hangs just below the stitching you just made on the front side of the band. Machine stitch from the front side of the band. Place the stitching as near the edge of the band as you can. Press before you stitch. It will flatten the seam and make stitching easier.

Press your skirt

Press your skirt. Use a dampened cheese-cloth and an iron set for ironing cotton, or use a steam iron. A skirt must be well pressed and fresh looking to be pretty.

[Illustration: Pressed skirt]

Fastenings for the skirt

[Illustration: Fastenings]

Study the drawing above. It shows the placing for fasteners on your skirt. Sewing them in this position will keep the placket from gaping. Sew a snap fastener in the center of the placket if it is needed to keep it closed. Do not try to set in a zipper. Use hooks and eyes or buttons for fastening this band.

Buttons and buttonholes—When buttons and buttonholes are used, make the buttonhole lengthwise of the band. Place it far enough from the end of the band so there will be at least ¼ inch beyond the button when it is sewed in place. Measure half the distance across your button and add ¼ inch for this measurement.

Learn to use the machine attachment for making buttonholes. They are stronger and easier for you to make than hand-made buttonholes. Have your leader, mother, or a neighbor set it up for you and show you how to use it. After you have made a few sample buttonholes, make some in your apron or on your skirt. If you have a machine with a zig-zag stitch, learn to make buttonholes on it.

Pin the band together and mark place for buttons. See page 2 for instructions for sewing on buttons.

Sew fasteners to skirt band

Snaps—Examine the snap fasteners. One part has a ball on top. This is placed on the front part or top of your placket. The other part has a hole or socket and is placed on the back or under part of the placket. Place them exactly opposite each other on your placket.

Sew the top snap on first. Mark the placing of the bottom part of the snaps by rubbing chalk on the ball and then pinning placket together. Press ball against fabric. The chalk will rub off and mark the exact spot to sew the under part of the snap.

[Illustration: Snap fasteners]

Sew snap fasteners on with several over-and-over stitches. Be sure to hide your knot under the snap. Sew securely through all four holes. When you cross from one hole to the other, take a stitch in the cloth and bring your needle up from the under side to the next hole.

Hooks and eyes—Each package of hooks and eyes, has two types of eyes, a round and a straight. Use the round eye for your skirt. Sew the hook on the inside edge of the top part of your band. (You will need two.) Sew these with several over-and-over stitches.

[Illustration: Hooks and eyes]

Sew several stitches through the hook end. Pin the placket in place and place the round eye directly under the hook. Sew with several over-and-over stitches.

Press all the things you have made. Pressing will improve their appearance. Make sure they are clean.

Have each member of your club judge what you have made and then make the corrections they suggest.

How does your apron or skirt look to you?

Once again, score your own and other club members' work. These are the points to use in judging:

Your score

1. Fabric or trimming used 25 _____ Is it suitable for aprons and skirts? Will it launder? Will it wear well? 2. Workmanship 35 _____ Are seams, hems, finish good choices? Are they well made? 3. Design and color 20 _____ Are design and color attractive? Are they right for you? 4. Condition of article 10 _____ Is it clean? Is it well-pressed? 5. Value of garment 10 _____ Is there good value for the time and money spent? Total 100 _____

Complete your record book

Your record book is important. Examine it carefully. Have you completed your clothing record? Have you recorded your activities as well as your project summary on your permanent record? Have you written your 4-H story for the year? In your story tell how you feel about the things you have made and the experiences you have had.

Each year your record book will add another chapter to your 4-H Club story. You will have fun looking back at each chapter as the years go by. Is this chapter as complete as you would like it to be?

You may want to keep a scrapbook of pictures and newspaper stories to go along with your record book.

Show others what you have learned

Exhibits

It is fun to let others see what you have done. Your club may want to plan a display for your families. You may want to exhibit your work at a fair. If you do, your exhibit will be the main article you made. Be sure your article is clean and pressed and clearly labeled so it can be returned to you.

Give a demonstration

A demonstration means "to show someone else how to do something." Select one small subject for your demonstration. Avoid one that has too many parts or details. Here are some suggestions:

How to sew on a button How to make a pocket How to shine your shoes How to thread a needle How to thread a sewing machine How to make a scarf How to make washcloth slippers How to make a mitered corner How to make a hem How to make gathers

How to make a sash for an apron How to make a skirt band How to make a hemmed placket

Because everything you use for sewing is small, you will need to make your samples large. Use contrasting thread, large stitches, and make large buttons so the audience can see what you are doing.

Are you ready for the next project?

1. Have you kept your shoes clean and shining? 2. Have you studied and improved your health habits? 3. Have you sewed buttons on family clothing? 4. Have you kept your record book up to date? 5. Have you made two or more articles?

Keep this bulletin. You will need it for your next project. When you have completed all the 4-H clothing projects, you will have a complete sewing book.

Zur Männerfrage!

Von

Clara Schott.

Leipzig, A. Bleier Verlag Nachf. Joh. Eckell 1898.

Alle Rechte vorbehalten.

Einleitung.

Um den Verdacht, ich sei eine Männerfeindin, nicht aufkommen zu lassen, halte ich es für geboten, gleich von vornherein zu bekennen, daß ich nichts weniger als das bin, daß ich mich im Gegentheil stets behaglich in Männergesellschaft befinde und freudig mit der Eleonore im Tasso sage:

»ich schweige gern, wenn klügere Männer reden.«

Und da ich das Glück hatte, vielen vorzüglichen Männern mit klarem Verstande und offnem Herzen zu begegnen, so hörte ich schweigend zu. Wenn sie mich nun reden hören, so werden auch sie, wie ich hoffe,

»verstehen wie ichs meine,«

so wie ich sie verstanden habe.

Ihr, meine Freunde, wißt, daß ich nicht ungerecht, noch weniger gehässig bin, und Ihr werdet mir beistimmen, daß die guten Männer nur Ausnahmen sind, denn Ihr kennt die Welt so gut wie ich. Ihr werdet mich auch nicht für den Fuchs halten, dem die Trauben sauer sind -- Ihr wißt ja, daß es nicht so ist.

Zu den Fremden, die meine Schrift lesen, sage ich: Wenn Ihr brav seid, braucht Euch dieselbe nicht zu alteriren, denn Euch klagt sie nicht an. Könnt Ihr Euch aber getroffen fühlen -- so schießt nur los, Eure Pfeile werden mich nicht verwunden.

Leipzig, im November 1897.

Clara Schott.

Männlich-sittlich.

Männlich-sittlich heißt mit Würde Tragen seiner Fehler Bürde: Bummeln, rauchen, Unfug treiben, Renommiren, schuldig bleiben.

Trinken, bis nicht Kopf, noch Magen Können länger es vertragen, Was nicht immer appetitlich, Das ist alles männlich-sittlich.

Heimlich zu der Liebsten gehen, Doch auf Zucht bei Andern sehen Und im Hause unerbittlich -- Das ist alles männlich-sittlich.

Ferner noch gehört das Spielen Zu den männlich-ernsten Zielen, -- Ei, was kann es Schön'res geben, Als so männlich-sittlich leben!

#Thusnelda Vortmann.#

Es ist wirklich sehr freundlich, das Publikum von heute. Wie viel Jahre läßt es sich nicht schon in allen Schreibarten, in Zeitungen, Zeitschriften, Büchern, Broschüren u. s. w. die Frauenfrage gefallen?

Immer und immer, von vorn und rückwärts gelesen, das Gleiche: Studentin -- Arbeiterin -- Dienerin -- lauter unverheirathete Frauen.

Und doch ist es nur _eine_ Frage, an der das Weib hauptsächlich krankt: es ist nicht die Brotfrage, sondern die -- Männerfrage!

Wie kommt es, daß sie bisher unaufgeworfen geblieben? Aus Respect? -- Aus allgemeiner Zufriedenheit mit dem Ewig-Männlichen?

Oder -- »und begehre nimmer und nimmer zu schauen, ... u. s. w.«? -- -- -- Ich glaube, der letztere Umstand hat viel dazu beigetragen.

#Der Schriftsteller# »studirt« das Weib, das er als ewiges Räthsel hinstellt. Er giebt vor, ihre Psyche zu belauschen, und was dabei heraus kommt, erzählen die vielen Cocotten-Romane, die in den letzten Jahren durch die Jungdeutschen in die Mode gekommen sind.

#Die Schriftstellerin# kann nicht belauschen, nicht »studiren«, aber sie vermag scharf zu beobachten und Erfahrungen zu sammeln. Und diese, gewissenhaft von Vorurtheilen getrennt, wiedergegeben, sind werth als Spiegelbild unserer heutigen »Ritter von der traurigen Gestalt« zu gelten. Sie sieht den Mann nicht als Räthsel an, sondern als das brutale Product seiner Erziehung, und als ein Wesen, das sich mit eingebildeter Uebermacht hochstellt und alle Rechte für sich beansprucht. Mit welchem gedankenlosen Selbstbewußtsein beansprucht, das wollen wir nachstehend illustriren. Wir geben reine Thatsachen, lassen alles Dichterische bei Seite und versuchen nicht mal zu retouchiren. -- -- --

Unsere Frauenrechtlerinnen sagen: wir sind im Nachtheil gegen die Männer, und bringen das Arbeitsgebiet -- auf das hier Hauptgewicht gelegt wird -- in den Vordergrund. Das »Ich bin« und »Ich werde sein« -- gewiß, es ist ein Feld, das sich als breites Terrain abgaloppiren läßt. #Allein, wer schützt das verheirathete Weib vor ihrem natürlichen Beschützer?#

»Oft sind ja die Männer Charmant und galant Und reichen uns Frauen Den Arm und die Hand.

Sie sagen, wir sollen Uns stützen auf sie, Das sei dann die richt'ge Weltharmonie.

Doch wenn wir sie rufen Uns Stützen zu sein, Sie lassen uns frierend Und hungernd allein.

Selbst brauchen die _Retter_ Ihr Geld, ihre Ruh, Die süßesten Freuden Des Lebens dazu.

Verlaß dich auf Keinen, Nur schau, nimmer trau, Und brauch' keinen Schützer, Denn selbst ist die Frau!« --

Des Weibes Vortheil liegt nicht im Wettkampf mit dem Manne, noch weniger liegt darin ihre Glückseligkeit. -- Diese kann nur gewonnen werden, durch die _Selbständigkeit des Characters_.

Die Frau soll dem Manne nicht die Peitsche aus der Hand nehmen, aber sie lasse ihn die Sporen fühlen. Ich meine nicht das Pantoffelheldenthum, das den Mann zur Memme herabwürdigt; aber was den Frauen fehlt, -- das ist das _würdevolle Selbstbewußtsein_ des Menschen.

Nur zu oft geht im Weibe der Mensch unter. Unsere Bräute, unsere Frauen -- was beanspruchen sie? Das ekelhafte »Beglücktsein«, dem Erwählten des Herzens »dienen« zu können -- es breitet einen blumenhaften Teppich vor dem »Herrlichen« aus, und vor ihm kniet das Weib mit erhobenen Händen: »Herr, was befiehlst du?«

Was? -- o, schrecklich viel!

Die Naivetät -- wir wollen keinen härteren Ausdruck wählen -- der Männer im Fordern und Herrschen ist von fabelhafter Keckheit. Der kleine Bruder »befiehlt« der kleinen Schwester, ihm mal die Puppe zu geben, die er ihr zerbricht. Weint sie, schlägt er einfach auf sie los, denn sie ist ja »nur« ein Mädel. Die größte Beleidigung für den kleinen Knirps ist, wenn er gelegentlich mal für ein Mädel gehalten wird. Wird er größer, so äußert sich sein Ritterthum darin, daß er nun »schon« Schulmädels »abdrischt«. Dann kommen die Flegeljahre, in die die meisten Männer wieder zurückkommen, wenn sie verheirathet sind.

Jetzt haben wir die Studien- und Lehrjahre. Vor allem ist das Studentenleben der Beleuchtung werth.

»Was studieren Sie denn?« fragte ich einmal einen jungen Herrn.

»Die Lumperei!« war die ehrliche Antwort.

Die Lumperei! Je toller sie es dabei treiben, je »fescher« werden sie bezeichnet. Gradezu ekelhaft ist es, daß unsere Witzblätter mit Studentenstreichen angefüllt sind und solche bei den jungen Leuten fast provoziren. Was für Witz liegt denn darin, Schulden zu machen, übermäßig zu trinken und Mädchen zu verführen? -- Ich setze den Fall, ein junger Kaufmann, oder Handwerker, mache fortwährend Schulden, kneipe, arbeite nicht und treibe allerlei Schabernack. Dann heißt es: »ein Taugenichts«, ein »verbummelter Mensch«, »arbeitsscheu«, »betrügerisch« u. s. w. Hier aber ist es -- weil es »sich ziemt«, auch »erlaubt«. Man hängt dem »Burschenschafter« ein buntes Bändchen um und läßt ihn laufen.

Bei Aufzügen und Commersen sehe man sich die »alten Herren« in Cerevis und diversen Abzeichen an. Was würde man wohl sagen, wenn »alte Damen« also markiert und frankiert herum laufen würden? -- --

Daneben gehen das schneidige Offizierchen, die Einjährigen, die Kaufleute, Beamte aller Arten, die alle um das »ewige Räthsel« herumflattern, es zu »erlösen« meinen, und so sich selber zu Liebe das Weib anbeten.

Und das Weib? -- Es sollte sich doch mal klar werden, was so die landläufige »Liebe« bedeutet, was so ihre »Ideale« eigentlich sind, an die sie ihre Gefühle und ihr junges Leben verschwenden! Wie viele blühende Gestalten sind nicht schon am »Amüsement« des Mannes zu grunde gegangen?! --

Haben sie dann genug hofiert, geschwärmt, Herzen gebrochen u. s. w., dann gelangen sie in das Stadium der Heirathskandidatur.

Hier giebt es eine Unmasse von Kategorien.

Es heirathen Gott Lob noch eine stattliche Reihe von Männern aus wahrer Liebe und gehen mit ehrlichem Pflichtgefühl in die Ehe. Dann kommt die Mehrzahl, die besteht aus:

Müden Seelen, die ein Ausruhebedürfnis haben,

Weltschmerzlern, die ihre Melancholie auf das Weib zu wälzen beabsichtigen,

Verschuldeten,

Solchen, die weder Geschick, noch den Muth haben, den Kampf mit dem Leben allein aufzunehmen, endlich

»Gemüthsmenschen«, die mit liebevollen Worten nach _außen_ verstohlen das Weib zur Dienerin ihres lieben Ichs herabzwingen und so nach und nach zwei bis drei Frauen florumwunden zu Grabe tragen.

Auch giebt es Männer, die sich Frauen für den »Hausbedarf« wählen und diese als Gegenstand betrachten.

Und die Weiber? -- wie schnell sie sich nur ergeben! als Braut hat auch jede den »herrlichsten von allen« für sich.

Thatsächlich leisten aber auch die Männer an Verstellungskunst so absolut das allerhöchste, daß sich die meisten während des Brautstandes mit Glanz behaupten.

Bevor ich nun daran gehe, einige Illustrationen zu geben, d. h. aus dem Leben gegriffene Spiegelbilder männlicher Tugenden zu zeigen, darf ich in meiner aufgezählten Kategorie der Heirathskandidaten eine Hauptserie nicht vergessen, die in allen Gesellschaftskreisen zu finden ist: nämlich die -- Heirathsschwindler.

Bei den Ehegesetzen, wobei die Männer alle, die Weiber fast gar keine Rechte haben, ja wo die Frau gewissermaßen als Leibeigene des Mannes betrachtet werden könnte, -- hat der Heirathsschwindler die weitestgehenden Chancen. Zunächst läßt er sich Haus und Hof einrichten. Damit ist er schon »Herr« im Hause, denn selbst in Ehen, wo die Gütergemeinschaft ausgeschlossen ist, hat der Mann -- was auch geschehe -- den Nutzen von allem, was da ist.

Und nun wollen wir einige Typen aus dem Leben herausnehmen. Es sind nicht nur wahre Gestalten, es sind Thatsachen, die ungeschminkt zeigen, daß die »#Männerfrage#« mehr der Beleuchtung bedarf, als die »#Frauenfrage#« an sich. --

Es ist noch gar nicht so lange her, daß ein »Aristokrat« eine Million geheirathet und mit sauersüßer Miene ein zartes Fräulein, das daran hing, in den Kauf nahm.

Rund 6 Wochen dauerte die »Ehe«, dann erklärte »er« dem nichtssagenden Puttchen, das sich so wohl als Frau Gräfin fühlen wollte: es könne nun gehen, ihr Geld sei in den besten Händen.

Es bedurfte allerdings erst der Reitpeitsche, bevor sie »ging«. Von ihrem Gelde erhielt sie natürlich keinen Pfennig heraus, denn die noblen Passionen des Mannes verschlangen eben alles was da war -- er hat ja von Rechtswegen den Nießbrauch und »brauchte« daraufhin so viel, daß am Ende des Prozesses nichts mehr vorhanden war.

Ein anderer »Herr« in angesehener Stellung ließ seine junge sehr verliebte Frau vor seiner Trauung selbst die Handschuhe für seine »Freundin« bezahlen u. s. w. u. s. w. Und nach der Hochzeit fiel es ihm gar nicht ein, seine Lebensweise zu ändern, obgleich er das beschworen, ebenso wenig in seinen Liebeshändeln irgend welche Rücksicht auf seine Gattin walten zu lassen. An einem Theaterabend, als die Gattin gerade ihren Fuß auf das Trittbrett ihres Wagens setzte, der sie nach Hause bringen sollte, erkühnte sich der Herr Gemahl sie zurückzuhalten.

»Den Wagen habe ich soeben Fräulein so und so (Name einer Schauspielerin) versprochen, Du kannst laufen!«

Nun war sie -- was leider ja vereinzelt dasteht -- keine nach Lyrikern gebildete Frau, sie zog nach Nietzsche ihre Hand zurück und zeigte »die Tatze« die »böse Krallen hat«. So kam es, daß sie ihn »laufen« ließ. Freilich, all die schweren Seelenkämpfe wurden ihr nicht erspart, aber sie ist noch Herrin auf ihrem Grund und Boden, und er bettelt sich irgendwo durch.

Nach den mehr gewaltthätigen Heirathsschwindlern, kommen die verkniffenen, die treten sanfter auf und wenden andere Mittel an.

Wir illustrieren sie mit nachstehendem:

Herr R. ist Gutsbesitzer in Polen. Seine Frau, die viel vornehmer als er, aus guter Familie, mit vorzüglichen Charaktereigenschaften, hat ihm das Vermögen zugeführt. Dafür muß sie, um Geld zu sparen, die Stelle der Mamsell vertreten. Da sie ihn lieb hat, ihr Interesse im Haushalt auch gern wahrnimmt, steht sie um 3 Uhr Nachts auf, überwacht rechtzeitig das Melken und bleibt auf, bis die Milchwagen in die Stadt gefahren sind. Tags über geht es Trepp auf, Trepp ab, die Landwirthschaft will besorgt sein.

Der »Herr« fährt recht oft zu einem Spielchen in die nahe Garnisonstadt. Die Frau kennt kein anderes Vergnügen, als alljährlich ein neues Sprößlein zu wiegen. »Er« murrt schon: »alle Jahre ein Kind, was das kostet!« An Geld, meint er. Die Lebenskraft der Frau -- daran denkt doch ein Mann nicht! Er hat auch schon vergessen, wer das Baby beim Storch bestellt!

Jetzt sind acht Jahre herum, die Frau ist acht Jahre im Dienste bei ihrem »Herrn«. Hier ist es aber so, daß sie den -- Lohn gezahlt, nicht er!

Es ist ja selbstredend, daß ein Weib arbeitet, wozu heirathet man es?! -- Das Geld ist alle. Wieso? -- Das weiß der Mann, und das genügt!

Der »Herr« wird nervös, alles reizt ihn, am meisten die Frau, die nichts mehr recht machen kann. Er will hier fort und zieht mit Frau und fünf Kindern in die Stadt -- in ein Haus, wo seit Jahren seine Maitresse wohnt, die er die Frechheit hat, seiner Frau als »Nachbarin« vorzustellen.

Und nun bekommt die »Nachbarin« das Regiment, und es geht mit dem letzten Heller des Vermögens bergab, der Mann ohne Thätigkeit, die Frau vor Leid krank. Schlußpointe, des Mannes Frage, die alles besagt:

»Weshalb hab' ich Dich eigentlich geheirathet, da Du doch nichts verdienen kannst?«

No. 4 hat eine Schriftstellerin geheirathet, weil ihn ihr edler Beruf, ihr Geist und schließlich ihre liebliche Gestalt »anzog«.

Wie bald merkte das arme Wesen, daß sie ihn thatsächlich »angezogen!« Vom Kopf bis Fuß sogar. Von den Stiefeln bis zum Hut hat sie indirekt alles bezahlt.

»Mein Lieb, jetzt soll die Feder ruhen,« hatte er ihr am Verlobungstage gesagt. Der Gute, Zarte, wie wollte er alle Lasten von ihr nehmen! --

Vier Wochen nach der Hochzeit:

»Möchtest Du nicht wieder etwas schreiben, Herzchen? -- Es ist nämlich, Du weißt, wenn eine Künstlerin vergessen wird, das thut nicht gut.«

Das sieht sie ein. Und noch mehr sieht sie ein! Der Schuft hat sie gefangen, und nun heißt es arbeiten, um all die Schulden, die das Hauswesen hervorgerufen, zu bezahlen.

Sie gleicht sich nicht mehr, sie ist blos noch eine Schreibmaschine im Hause.

Es kommt ein Quartal, wo die Miethe nicht bezahlt werden kann. Die Verleger sind nicht pünktlich, sie schreibt und schreibt um Geld -- keine Antwort. Da erbietet sich der Edle, ihr Mann, die »natürliche Stütze«, für sie einzutreten. Wie gut, wenn man verheirathet ist!! Vor einem Mann hat man doch ganz anderen Respekt. -- Schon darauf bauend, reist er nach S. und erhält sogleich 500 Mark ausgezahlt.

Natürlich sendet er ihr ein Telegramm, damit sie daheim von der Sorge befreit ist, setzt sich auf die Bahn und fährt über Leipzig nach Hause. In rosiger Stimmung natürlich, er hat ja Geld!

Hier trifft man ein paar Freunde, mit denen man ausgeht, und auch ein paar hübsche Pflänzchen. Die eine ist reizend und findet so viel Gefallen an dem auf Reisen geschickten Ehemann, daß sie es unverhohlen zeigt. Und wenn ein Mann gefällt, bei der angeborenen Eitelkeit, dann kommt sehr schnell die angeborene Untreue hinzu.

Der Edle vergißt seine Frau und kauft für deren sauer verdientes Geld einen Schmuck für die Dirne. Allerdings amüsiert er sich dafür prächtig, und das ist doch auch etwas werth! -- Soll ich noch aus höheren Kreisen Copien bringen, oder soll ich herabsteigen in die einfachste Klasse, wo die Sparkassenbücher eine rührselige Rolle spielen -- -- -- »und begehre nimmer und nimmer zu schauen« ....

Nun giebt es noch eine liebliche Sorte -- Verlobungsschwindler, die gegen freie Kost und Logis frisch drauf loslieben. Und zwar so lange, als es ihnen dienlich erscheint. Dann untergraben sie in irgend welcher Weise den guten Ruf der Braut, damit die »Welt« ihren Rücktritt nicht etwa verdamme -- so etwas könnte bei der nächsten Parthie schaden --, und verschwinden.

In einer Berliner Zeitung hieß es einmal: ein hoffnungsvoller Jüngling sei auf drei Stellen zu gleicher Zeit »verlobt« gewesen. Bei den »Schwiegereltern« der ersten Braut wohnte er, bei der zweiten Braut, einer Schneiderin, aß er, und der dritten, einer Putzmacherin, nahm er ihr Geld ab, mit der Weisung, dafür wolle er ein Geschäft kaufen.

Von London aus, wohin sich auf Kosten der Putzmacherin der Verlobungsschwindler gewandt, erhielten alle drei »Bräute« gleichlautende Zettel:

Für die Zeit, wo Du mich geliebt hast, Bedank i mich schön, Und i wünsch, daß Dir's Jetzt nun besser mag geh'n!

Wir sehen davon ab, aus der besseren Gesellschaftsklasse noch »Illustrationen« zu bringen, es dürfte den Leser ermüden. Jedoch einen Brief hier abzudrucken, den mir eine Dame zur Verfügung gestellt, möchte ich nicht unterlassen. Es spricht so viel zarter Dank für genossene Liebe daraus und er birgt so viel echtmännliche Gewissenhaftigkeit, daß er mein Spiegelbildchen vervollständigen hilft.

»Lieber Gustav!

Das war eine rechte Freude, das ist ja famos, da habe ich auch wieder mal kolossales Schwein! Du sollst nämlich mein Retter in der Not sein. Diesmal nicht in Geldangelegenheit -- ich habe meine hiesigen Gläubiger sehr gut erzogen --, sondern Du sollst mir helfen -- nicht wie damals _eine_ zu bekommen, sondern _eine_ los zu werden. Es müßte mit dem Teufel zugehen, wenn solch patenter Kerl, wie Du bist, das nicht leicht zu Wege brächte!

Die Martel wird mir unbequem, das Verhältniß war der dümmste Streich meines Lebens, die nimmt die Sache ernst und ich sage Dir -- ich wäre lieber wo der Pfeffer wächst, als hier. Die taxiert sich hoch und sagt sehr freimüthig »mit jedem Jahre lerne ich mich mehr lieben und mehr schätzen, weil ich mich besser kennen lerne.« Thatsächlich wird sie mit jedem Jahre üppiger. Aber Bester, ich habe grade genug und will überhaupt fort, es ist hier öde und aufregend zugleich.

Da Du doch, wie Du schreibst, nach H. gehst, kannst Du mir zu Liebe schon den kleinen Abstecher machen. Ich stelle Dich ihr vor, und hübsch, wie Du bist, und wie ich ihren Geschmack kenne, machst Du ohne Zweifel kolossalen Eindruck. Das übrige überlasse ich Dir ... Ich spiele dann den Eifersüchtigen und sichere mir damit einen respectablen Abgang.

Also ich rechne bestimmt auf Dich, so wie Du stets auf meine Dankbarkeit rechnen kannst. Telegraphiere wann ich Dich erwarten kann.

Dein K.

Dir gebe ich den guten Rat, Dich nie an brünette Weiber heranzumachen, die sind von einer verfluchten Anhänglichkeit.«

Man sieht, sie arbeiten mit allen Mitteln, die Herren Männer, und sie sind ja so schlau, so schlau, daß man gar nicht begreift, wie man einstens die Weiber mit der Annahme beehren konnte, sie seien »schlau wie die Schlangen!« -- --

So lange der Mann keine Verpflichtung hat, sieht er im Weibe das anbetungswürdige Geschöpf; gesellt sich zu seiner Anbetung und Liebe aber die Pflicht, so ist es aus. Er ist immer berechnend, und wo die Rechnung quittirt ist, wo nichts zu holen, so oder so, da hört nach und nach jeder Reiz auf.

Und nun kommen wir zu dem Punkt der Treue, und das ist ein sehr wunder Punkt!!

Der Mann kann sich selber, dem Freunde, im Handel und Wandel treu sein -- dem Weibe ist er es höchst selten. Fast immer wird es von ihm hintergangen. Ist es nicht mit einer Freundin, ist es mit einer Unbekannten. Für sie ist wenig vorhanden, für die Geliebte immer Ueberfluß. Bei der Frau knausert man, der Geliebten will man imponieren, nichts ist zu theuer für sie. Natürlich gilt dies bei Männern besser begüterter Stände, die überhaupt etwas zu geben haben. Die Mittelklasse steigt tiefer. Vielen Hausherren haftet leider auch die Dienstmädel-Manie an, und nicht vielen Frauen wird die tiefe Scham erspart, von den Mädchen selbst zu vernehmen, der »Herr stelle ihnen nach«!

Bei den besser gearteten Männern regt sich dann das Gewissen und ihre Zärtlichkeit für die Gattin verdoppelt sich nach einer solchen Missethat. »Mein Mann muß mich wieder hübsch hintergangen haben,« sagte einmal eine Dame, »er hat mir aus eigenem Antriebe einen Pelzmantel gekauft.«

Würde dieses »Hintergehen« nur allein das Gefühl der Frau verletzen, so wäre es noch nicht gar so schlimm und zu überwinden, aber es sind ganz andere Gefahren dabei! -- Der Mann zeigt selten die volle Theilnahme an einem Erkranken der Frau, als es oft umgekehrt der Fall ist. Er klagt, so bald sie leidend, zunächst, daß das Hauswesen ins Wanken kommt, nebenbei erst thut es ihm gelegentlich leid, daß sie nicht gesund ist. Darüber läßt er sich dann gern bemitleiden -- auch eine typische Eigenschaft des Mannes --, denn am Ende -- es ist doch höchst lästig eine kranke Frau zu haben!

Als einmal ein Freund dem anderen klagte, daß seine Frau ewig leidend und schon in drei Bädern gewesen, was das koste! schrieb dieser zurück: »Für die Reparaturkosten hättest du schon eine neue gehabt.«

Woher aber die vielen Frauenkrankheiten kommen, davon wissen Aerzte und Aerztinnen zu erzählen! Eine derselben, die seit 12 Jahren in Deutschland eine blühende Praxis ausübt, kann nachweisen, daß von 100 Patienten, 70 ihren Männern die Krankheit verdanken.

Und diese haben dann natürlich »ein Kreuz« mit den »Weibern«, die ewig klagen und so viel kosten!

Und während ich die »Männerfrage« beleuchte, tönt eine andere an mein Ohr: »Giebt es denn gar keine guten Männer??« -- O ja, viele, viele prächtige Männer, ganze »Kerle« mit Herz und Verstand, mit Seele und Gewissen, aber mit ihnen geht es wie mit den Weibern:

#Von den besten spricht man nicht!#

Von dem Gros aber, das sich mit seinen vielen Arroganzen so hoch über das Weib stellt, muß gesprochen werden. Die Fehler der Frau kennt jeder, sie sind in allen Formen bloß gelegt worden; vom minderwerthigen Gehirn, bis zum eitlen Tand, mit dem sie sich umgiebt, hat der Mann gesprochen, es gehört ja alles zur #Frauenfrage#.

Nun aber werfen wir die #Männerfrage# auf, und wir werden ja sehen, wie weit sie führen wird, sehen, ob die »Herrlichen« -- weß Standes sie seien -- ewig nehmend, ewig fordernd, sich behaupten werden. Und wie naiv die Herren der Schöpfung im Fordern sind -- das ist einfach fabelhaft.

Wenn man sie reden hört von ihrem Standpunkt aus -- ich weiß nicht, ob man darüber lachen oder weinen soll.

Fahre da einmal von Frankfurt a. M. nach Leipzig. In Eisenach steigt ein Herr ein, der sich veranlaßt fühlt, eine Unterhaltung anzuknüpfen.

»Nein, ich heirathe nie!« erzählt er mir im Laufe einer zweistündigen Fahrt. »Nie, denn die Weiber von heute! -- Ich verlange von einer Frau 1. natürlich Vermögen, 2. Schönheit, 3. Bildung, 4. gute Familie.

Sie muß wirthschaftlich sein, darf keine theure Roben tragen, muß selbst kochen und mir in meinem Beruf behülflich sein.«

»Hm,« machte ich, »wie ist denn die Gegenleistung?«

Er sah mich verständnislos an.

»Na wie denn, die Gegenleistung? -- Sie scherzen wohl?«

»Durchaus nicht, Sie müssen doch, wenn Sie so vieles verlangen, etwas bieten können.«

»Ich? -- na, ich heirathe sie doch! Sie ist doch ihr lebtag versorgt.«

»Wenn die Dame Vermögen bringen und arbeiten soll u. s. w., so könnte sie sich doch mit diesen hübschen Eigenschaften recht fidel selbst »versorgen«.« (»Versorgen« im Sinne der heutigen Männer heißt gewöhnlich mit Sorgen überschütten.)

»Na, wissen Sie, Gnädigste, bei solchen Auffassungen würden die meisten Mädchen alte Jungf...« er sah ängstlich nach meiner Hand.

»Früher, mein Herr, hat man »alte Jungfer« im verächtlichen Sinne gesagt. Heute -- nun erst beginnt man das Symbol des Eheringes zu verstehen!

Die Hand ohne Ring ist das Freizeichen. Die »alte Jungfer« lebt nicht mehr. Heut ist die #Unverheirathete# die #Freifrau#, die unabhängig von einem Haustyrannen ihren Weg macht. -- Die Hand #mit dem Ringe# aber sagt: Ergeben auf Gnade und Ungnade. Bitte, mein Herr, sagen Sie mir, wessen Loos ist besser, das der »Freien« oder der »Gebundenen«?«

Der Mann verlangt von der Frau alles. Sie soll ihm Kinder geben, ihm dienen, kochen, sparen, helfen, wo immer sein, im Geschäft, Bureau, Werkstätte u. s. w. Er selbst aber ist eben entweder nur Fachmann, oder mit einem Worte Verdiener. Sie aber soll universell sein. -- -- --

Von der großen Masse Ausnahme-Männer, die Würde genug besitzen, sich ihr Haus selbst zu gründen und es pflichtgemäß auch selbst zu erhalten, hört man oft bewunderungsvoll sagen: »er hat sich ein armes Mädchen geheirathet!«

Erstens: Ist denn eine Menschenseele absolut nichts werth? Und besitzt die Frau an sich nicht schon all die Eigenschaften, die der Mann absolut gebraucht? Sie bezahlt mit ihrem #ganzen Sein# schon genug Entrée für den Eintritt in das zweifelhafte Glücksinstitut der Ehe. Der Mann sollte mal nachrechnen, was er zu bezahlen hätte, wenn er nicht verheirathet wäre! Da kommt erst: Ein sogenanntes Verhältnis, das Geld kostet. Eine Wirthschafterin, die hoch bezahlt wird, und die lange nicht so rechnet, als eine Frau, die ihre eigenen Interessen vertritt. Eine Ausbesserin der Wäsche und Garderobe und diverse Vereine, in denen er seine freie Zeit verbringt, weil er kein eigenes Haus besitzt. Kurz -- man sieht, der Mann ist #viel besser# in der Ehe »versorgt«, als die Frau, die die größeren Lasten übernommen! --

Zu den weiteren naiven Eigenschaften der Herrn Männer gehört auch die, ihre Untugenden auf Rechnung der Weiber zu setzen.

»Sie« hat ihn betrogen -- #deshalb# hat er sich dem Trunk ergeben, #deshalb# hat er sich in den Strudel des Lebens gestürzt.

Weil #die Frau# die Wirthschaft vernachlässigt -- geht er in die Kneipe. Weil #die Frau# nicht geschäftstüchtig ist, verdient er nichts u. s. w. Ergo: gäbe es keine Weiber, es liefen lauter männliche Engel herum.

In Ausreden sind die Männer überhaupt fabelhaft gewandt und im Abwälzen ihrer Fehler auf andere virtuosenhaft.

Die ekelhaftesten aller männlichen Specien aber sind diejenigen, die ewig heulen.

Unter Thränen schwören sie Treue. Unter Thränen brechen sie dieselbe und versprechen Besserung bis zum nächsten Mal.

Unter Thränen geben sie der Frau einen Versöhnungskuß und küssen unter Thränen lächelnd das holde Lieb zweiter Garnitur. Und dann die freimüthigen Geständnisse, die sich mit ahnungsloser Unverschämtheit zusammen finden!

Man höre:

»Ich bin sehr jähzornig -- #deshalb# muß ich eine sanftmüthige Frau bekommen.«

Nein, Herr der Schöpfung, #deshalb# mußt du hübsch Selbsterziehung üben und Dir hübsch manierlich diese heillose Untugend abgewöhnen, nicht aber über das Haupt einer Sanftmüthigen ergehen lassen. Oder: »Ich bin ewig mürrisch und verdrießlich, #deshalb# muß ich eine heitere Frau bekommen.«

Ich möchte sehen, wessen Heiterkeit ein ewiger Griesgram nicht verscheucht! --

Nun geben sich eine ganze Masse kreuzbraver Männer, die ihr Lebtag nichts Böses thun könnten, für Herzensbrecher u. s. w. aus und renommieren mit Unthaten, die ihr ästhetisches Gefühl schon nicht zuließe, um »männlich« zu erscheinen. Was für Lob für die Allgemeinheit hierin liegt, kann sich ein Jeder wohl ausmalen! --

Die Neuzeit hat noch eine Art Männer herangebildet: Rhetoriker.

Am allerschlimmsten ergeht es denjenigen Frauen, die jene Sorte von Maulhelden geheirathet haben. Ganz besonders wenn sie in politischen Versammlungen von gleichen Rechten faseln, um sich dort Weihrauch zu streuen. Sie haben erwiesener Maßen weder Herz für ihre Familie noch Verstand genug, irgend Jemanden zu beglücken. Ihre erheuchelte allgemeine Menschenliebe ist nichts weiter als die Sucht, sich bewundern zu lassen, als die geistige Koketterie, sich reden zu hören, denn in Wirklichkeit lieben die »Volksbeglücker« einzig und allein nur sich selbst und sind im eigenen Hause der rasende Roland. Von dem Elend der Ehefrauen, die sich durch die Zungen-Gymnastik der »Beglücker«, der »Kämpfer für Freiheit und Recht«, haben bethören lassen, ist nicht zu erzählen.

Man versetze sich in die Lage einer Frau, die ihren Gatten salbungsvoll der »Menge« predigen hört, wobei er in Ethik überfließt und in Achtsamkeit und Ehrlichkeit einzig dasteht, und die genau weiß, daß seine Handlungsweisen dem entgegen laufen, und daß er alle die Laster und Untugenden, die er öffentlich beklagt und verwirft, im hohen Maße selbst besitzt! Im Hause »rettet, rennet, flüchtet« alles, wenn er sich zeigt, weil man ihn fürchtet, »draußen« ist er ein Mann der Humanität, ein Engel ohne Flügel, der herabgekommen, um dem Unterdrückten zu seinem Rechte zu verhelfen.

Ist das alles nicht werth, aufgezeichnet zu werden? Vielleicht halten unsere Herren einmal Selbsteinkehr und sie werden nicht zu kurz dabei kommen.

Eine Ungerechtigkeit, an der allerdings der Mann nicht schuld ist -- die sich aus unserer gesellschaftlichen Lage ergiebt -- ist es auch, daß des Weibes Stellung vom Manne bedingt wird.

So kommt es, daß eine zur Gräfin erhobene Magd mehr gilt, als eine vollendete Dame, die einen in bescheidenen Verhältnissen lebenden Mann geheirathet hat.

Die Frau fällt oder steigt durch die Heirath, dem Manne läßt man Rang und Würde, er mag wählen, wie es auch sei.

Warum kann sich das Weib ihre Stellung nicht selbst bestimmen, wenn sie die Fähigkeit dazu besitzt? -- Unsere Frauen aber sind -- besonders in kleinbürgerlichen Kreisen -- sehr gern geneigt, in dem Manne »aufzugehen«.

Es ist fast lächerlich, wie viel manche Damen auf Titulatur geben. Der ärgste Schuft, der neben der Schufterei noch etwas gelernt hat (Schufte sind fast immer intelligent zum Nachtheil ihrer Mitmenschen), hat, sobald er einen »Rang« bekleidet, Chancen, denn Fräulein Soundso drückt gelegentlich mal ein Auge zu, bei der fraglichen Moralität ihres Zukünftigen, wenn sie von da ab Frau Ober-Soundso sich nennen kann.

Man beobachte mal die Kaffee- und sonstigen Gesellschaften, in denen die Vorstellungen ja eine so wichtige Rolle spielen! Vor allem liebt es die Wirthin, mit ihren Eingeladenen zu glänzen. Oftmals mit der größten Nichtachtung vor der Person, die sich zufällig emporgeheirathet hat, im Herzen, ruft sie -- wenn volltönend -- mit gehobener Stimme deren Aushängeschild aus.

Putzig war es, als eine Dame ein Fräulein =Dr. ph.= einer Appellationsgerichtsräthin vorstellte. Der Tonfall besorgte alles! »Frau Ober--appellations--gerichts--räthin ....« Einige Töne tiefer: »Fräulein =Dr.= S.«

Die hübschen Augen der Philosophin lachten mich an.

»Ja, was wollen Sie,« tröstete ich, »Sie haben nur sechs Buchstaben vor Ihrem Namen, die Sie sich noch dazu mühselig erarbeiten mußten, und diese Dame stolzirt mit 26 solcher herum, die ein anderer auf ihr vergoldetes Schild getragen!« -- Und die Titelsucht ist nicht nur in den Kreisen des Scheins, sie reicht bis zur Frau Ober-Straßenfegerin hinab.

So kommt es also, daß die socialen Verhältnisse die Frauen dahin bringen, daß sie mit ihren Männern prahlen, obwohl sie vielfach wissen, daß sie dem Charakter nach mehr sind, als diese.

Gradezu »gefährlich« -- im komischen Sinne, sind auch diejenigen Männer, die von ihren Frauen »nicht verstanden« werden.

Ich kannte ein Ehepaar, wo der Mann freilich diverse Vocabeln mehr wußte, als die Frau, der auch dickbändige wissenschaftliche Werke geschrieben und Forschungsreisen gemacht hatte. Aber seiner Frau gesunder Menschenverstand und ihr köstlicher Humor standen doch turmhoch über seiner griesgrämigen Gelehrsamkeit, und doch war sein ewiges Seufzen: »Dieses Weib ist nicht bedeutend genug, meine Bedeutung zu verstehen!« Als er sich aber einmal in die Tinte hineingeritten hatte, war »dieses Weib« bedeutend genug, der Geschichte eine andere Wendung zu geben, und in den Tagen der Noth war sie »das treue Weib«, seine »Stütze«, sein »Halt«. Die ganze verkrochene Feigheit des »bedeutenden Mannes« trat hier grell zu Tage.

Das sind so komische Figuren, Kleinigkeiten, die charakterisiren helfen, etwa wie die Momentaufnahmen auf den Straßen, wo wir jetzt auch Gigerl, als Zärtlichkeits-Aeußerungen, auf den Arm junger Mädchen gestützt, sehen. Früher führte sehr galant der Ritter seine Dame, #die Frau stützte sich auf den Mann#. Heute lassen sich die Männer von jungen Mädchen führen. Symbolisch gar nicht übel! --

Und nun -- das ist ein Punkt, der mir auf der Seele brennt! Ist es wirklich ein Fortschritt der Cultur, daß das Vaterrecht herrscht? -- Ich glaube der Irokese, der im Urzustande nach seinem Herzen das Mutterrecht gelten ließ, war weiter wie wir; dem Weibe gehörte das Kind, das sie trägt, gebärt. Es ist ihr Fleisch, ihr Blut und ihr Geist. Am besten kann man diese Wahrheit bei denjenigen beobachten, die außerehelich geboren haben.

Beim schlechtesten Weibe dringt selbst in der verzweifeltsten Situation das Muttergefühl durch. Sie bringt ein Kind zur Welt in Schimpf und Schande, in Noth und Elend. Und doch, in Lumpen gehüllt, trägt sie es am Herzen mit sich herum. Der Vater? -- oft weiß er überhaupt nicht, daß er ein solcher ist!!

#Und dies allein spricht von Natur aus der Mutter das Kind zu!#

Weiß er es aber, freut er sich darüber?? --

Das kraftloseste, verlassene Weib arbeitet bis zum letzten Athemzuge für ihr Kind, oder erbettelt sich die Nahrung für dieses. Der Vater will oftmals nichts von seinem Ueberfluß für dasselbe geben. Er ist ganz Genuß, die Mutter ganz Entsagung.

Trotzdem hat der roheste Patron, der zufällig Vater ist, das alleinige Recht über das Kind der Mutter. Wie viel Trunkenbolde und Spieler giebt es nicht, denen das gesetzliche Recht zusteht über die Zukunft des Kindes zu bestimmen! --

Kommen wir nun wieder auf unser eigentliches Thema zurück!

Für die Frauenfrage interessirte sich der Mann bisher:

1) wenn er heirathen will aus beliebigen Motiven;

2) wenn er sich am Weibe »zu berauschen« beabsichtigt;

3) wenn er es loswerden will.

Bei den Frauen aber gab es nur eine Männerfrage, die da lautet: »wo bekomme ich einen?«

Diejenigen Frauen, die durch Schiller und Goethe die männlichen Helden kennen gelernt haben, wissen, daß sie #nur# durch »Dienen« zur #Herrschaft# gelangen (ja freilich!) und geben sich daraufhin zu allem her.

Die Backfische, die Chamisso's Syrup

»Seit ich ihn gesehen, Glaub' ich blind zu sein« u. s. w.

hinhimmeln, die gehen mit einem suggerierten Idealismus in das Eheglück hinein. Freilich, klug ist es nicht, daß unsere Mütter ihren Töchtern all die veralteten Melodien in die Hand geben. Unsere Zeit ist eine andere. Es leben andere Menschen, es sind andere Verhältnisse. Die Töchter dürfen nicht mehr »blind sein«, seit sie ihn gesehen.

Nein, #weil# sie ihn gesehen, muß man ihnen die Augen öffnen!

Nach Chamisso ist ein anderer hehrer Geist herabgestiegen. Und seine gewaltige Stimme sprach:

»Manchen Menschen darfst Du nicht die Hand geben, sondern die Tatze, und ich will, daß Deine Tatze auch Krallen habe.«

Wäre dem so, der Mann und die Frau, beide wären sie glücklicher. Aber es giebt so verschiedene Arten von Weibern, die, obzwar sie in der Welt Bescheid wissen, doch singen:

»Eines Mannes schönste Tugend Ist nicht Keuschheit, noch ists Jugend, Ist nicht Schönheit und Verstand, Ueberfluß an Geld und Land.

Auch nicht Stellung ists, noch Titel, Nicht der Rock, noch bunter Kittel, Dann erst lob' ich mir den Mann, Wenn ich ihn noch kriegen kann.«

Aber die edle Frau, die aus kühler Ferne beobachtet, ohne Herz und ohne Galle sprechen zu lassen, die gleichgültig lächelnd vom hohen Balcon herabschaut auf das Treiben der Männlein und Weiblein, die singt ein anderes Lied, das da lautet:

»Seit Amor sich hat verwundet Mit seinem eigenen Pfeil, Reist er in olympische Bäder Zu suchen dort sein Heil.

Er hat ein krankes Herze, Seit Psyche ihm entfloh, Nicht mag er mehr regieren, Wird nicht des Lebens froh.

Nun aber treibt auf Erden Viel wüsten Spuk und Graus Ein täppischer Geselle, Giebt sich als Amor aus.

Er ist gemeiner Herkunft Und widrig von Gestalt, Verliebt und ganz vertrunken, Mit kahlem Haupt und alt.

Und fahl sind seine Wangen, Und frech der blöde Blick. Betäubend ist sein Treiben, Doch bringt er Keinem Glück.

Die Väter täuscht er Alle, Sie freut der glatte Wicht, Die Mütter aber seufzen: »Das ist der Amor nicht!«

Sie knieen nieder und beten: »O Göttin im Himmelsrund, Gieb Deinen Sohn uns wieder Und mach' ihn wieder gesund.«

Ja, das wäre was, wenn nochmals das alte Reckengeschlecht aufstände, mit ehrlicher Liebe, mit ehrlicher Leidenschaft, mit der Würde, die Ehrlichkeit im Handel und Wandel verleiht, durch die allein das Weib #vor# dem Manne beschützt werden kann. #Von# dem Manne beschützt zu werden, hat sie längst aufgegeben und auch nicht mehr nöthig: unser Jahrhundert ist anders geworden, der schlafende Riese hat sich geregt. Aber -- wenn sie nochmals käme, die goldene Zeit, die Männer erstehen ließe -- so wäre gelöst, #die Frauenfrage#, in der

#Männerfrage#.

Druck von G. Reusche, Leipzig.

[Hinweise zur Transkription

Das Originalbuch ist in Fraktur gesetzt. Darstellung abweichender Schriftarten: _gesperrt_, =Antiqua=, #fett#.

Der Text des Originalbuches wurde grundsätzlich beibehalten, mit folgenden Ausnahmen,

Seite 5: "ihr" geändert in "ihre" (Er giebt vor, ihre Psyche zu belauschen)

Seite 7: "erhobenenen" geändert in "erhobenen" (vor ihm kniet das Weib mit erhobenen Händen)

Seite 7: "Witzlätter" geändert in "Witzblätter" (unsere Witzblätter mit Studentenstreichen angefüllt)

Seite 10: "in in" geändert in "in" (die Milchwagen in die Stadt gefahren)

Seite 15: "," entfernt hinter "vielen" (mit seinen vielen Arroganzen so hoch über das Weib)

Seite 21: "Überfluß" geändert in "Ueberfluß" (von seinem Ueberfluß für dasselbe geben)]

A SHORT TREATISE

ON

BOOTS AND SHOES

ANCIENT AND MODERN,

BY

Walter H. Goater.

Presented by

J. & J. Slater,

1185 Broadway,

N. W. COR. OF 28TH STREET. New York.

Boots and Shoes, Ancient and Modern.

As far back as we can trace the early history of man, under civilized conditions of life, we find that shoes of some kind have been worn.

At first they were very crude and simple, being nothing more than soles fastened to the foot by means of thongs or straps, which passed between the toes and around the ankle, like Figs. 1, 2, 3. Shoes of this description were called sandals, and were worn by the ancient Egyptians, Greeks, and Romans.

It has been discovered, by means of paintings on the walls of Thebes, that shoemaking formed a distinct and quite lucrative trade away back in the reign of Thothmes III., some fifteen hundred years before Christ, so that followers of the awl and last can truthfully boast of the great antiquity of their profession.

The material chiefly employed in the manufacture of shoes, from the earliest times to the present, has been leather, though stuffs of various kinds and colors have entered into their composition at different periods.

The sandals worn by the priests of ancient Egypt were generally made of palm and papyrus leaves fastened together. Some well-preserved specimens of these sandals, obtained from tombs, can now be seen at the British Museum, in London.

[Illustration:

Fig. 1.

Fig. 2.

Fig. 3.]

Such were the shoes probably worn by Rhodope, the Cinderella of the Nile. Rhodope was said to have the loveliest foot in all Egypt. One day, as she was taking her bath, an eagle stooped from Heaven and carried off her sandal. She watched him as he soared on high, until he finally disappeared in the distance.

When, after a time, he let the sandal drop, it fell at the feet of the King, who was so charmed with its beauty that he commanded that a search be made immediately for its owner. Rhodope was soon discovered, and shortly afterwards became the Queen of Egypt.

* * * * *

In both ancient Greece and Rome we find that, while it was common for the women to wear some kind of a foot covering, shoes were not generally worn by the men or youth, the latter always being taught to go barefooted. But later on, on ceremonial occasions, the magistrates began to wear a red shoe, while the soldiers took to a boot reaching almost to the knee, very elaborate in design, and in a short time the custom of wearing a covering for the feet was adopted by all classes. The shoes of the women were always white in color, the senators black, while the magistrates kept to themselves red.

* * * * *

[Illustration:

Fig. 4.

Fig. 5. _Fig. 6._ _Fig. 7._

Fig. 8.]

In eastern countries we find the Japanese wearing a shoe of rice and straw woven together (Fig. 5). This material is very light and soon wears out; so, when starting on a journey of any length, it is customary to take a number of pairs of shoes with one, leaving the old ones along the roadside as they become unfit for use.

The Japanese, on entering a house, observe the same rule as the Turk on going into his mosque, always taking off their shoes and leaving them at the threshold, lest they might soil the door-mats, for which they have a peculiar and marked respect. The military in Japan wear a kind of clog, covered with movable metallic plaques (Fig. 4). To this is attached a sole of wood or plaited straw, which is held on the foot by means of a roll passing between the toes.

The Chinese, we all know, have, for ages past, religiously devoted themselves to dwarfing the feet of their women of the higher classes, so that it is not at all uncommon to find a full-grown woman with a foot as small as a child’s of four or five with us.

Of late years this barbarous custom has been gradually dying out, and now one can occasionally come across a woman whose feet have not been distorted; still, when they are allowed to wear shoes of natural size and form, they are usually fixed on high, conical soles, like Figure 8, which renders walking very difficult. But the Chinese women are not expected to walk much, as their lives are passed in seclusion and retirement.

[Illustration:

Fig. 9.

Fig. 10.

Fig. 11.]

Some of the shoes worn by the ladies are very beautiful, indeed (Figs. 6 & 7), being made of delicate pink and blue satin embroidered with birds and flowers.

The men generally wear black satin boots with white soles, which they lay off in summer for shoes made of plaited bamboo, with cork soles.

In India, shoes are worn only by the higher classes, and a few of the lower castes. This habit of going shoeless seems to render the toes of the Hindoo almost as lissom as fingers. Sitting at his work, if his hands are employed he can use his feet to pick up any article he may require, as the big toe becomes quite prehensile.

Among the Persians we find that in ancient times one of low stature was generally looked upon with dishonor; hence arose high heels to repair the deficiency of nature. At first they were worn only by actors and actresses on the stage, but were afterwards adopted by all classes, even those whose stature required no additional height blindly conforming to the prevailing fashion, as many people do at the present day.

Some of the shoes worn in Eastern countries, at different times, have been very interesting (Figs. 9, 10, 11, 12, 13, 14).

[Illustration:

Fig. 12.

Fig. 13.

Fig. 14.]

Figure 11 shows a lady's shoe richly painted with small flowers. In front is a knob of brilliant color, divided into segments to imitate the petals of a flower, and at every step the wearer takes she presses a spring concealed under the sole, which causes the petals to alternately open and close. One can easily imagine the sensation such a shoe would cause, seen promenading along any of our prominent thoroughfares for the first time.

The shoes worn by the wealthy are of the richest description, being overlaid with gold and silver, and embroidered with precious stones. Others, like Figure 14, are adorned with inlaid work of pearls or delicate shells set in gold, closely resembling _cloissonne_ enamel, while many employ the wings of gorgeous insects in their decoration.

The color of shoes in the East seems to be a matter of importance, indicating the rank or caste of the wearer, red and yellow being the favorite shades.

In olden times the Mohammedans were very jealous that none should wear yellow but themselves, wishing it to be preserved as their distinctive mark; and there is an old story which tells how some charitable person gave a Christian beggar an old pair of yellow slippers, and the Sultan happening to see them had the old man thrown into prison, and despite his explanations and protestations of innocence would not spare his life.

* * * * *

[Illustration:

Fig. 15.

Fig. 16. _Fig. 17._ _Fig. 18._

Fig. 19.]

Leaving the East, and coming back to Europe, we find that in the early days of the Church at Rome there lived a pious man named Crispin, and his brother, who became converted to Christianity, and leaving their native village traveled into France and Britain.

While on their travels they supported themselves by making shoes, which they sold to the poor at very low prices.

(There is a legend which says that an angel supplied them with all the leather, which probably accounts for their moderate charges.) At any rate, they are said to have done a great deal of good among the poor, but were finally martyred for their faith, in the third century. Ever since their memory has been celebrated by the faithful of their craft with great rejoicing and merriment on the 25th of October, which is known as St. Crispin's Day, while he is considered the patron saint of all shoemakers.

* * * * *

In the ninth and tenth centuries, we find the use of wooden shoes, or _sabots_, very general throughout Europe, princes of all degrees wearing them. Their reign was of short duration, however, as they were soon relegated to the poorer classes, by whom they have been worn ever since.

[Illustration:

Fig. 20.

Fig. 21.

Fig. 22. _Fig. 23._

Fig. 24.]

One would think, from their clumsy appearance (Fig. 16), that it must be rather awkward work to walk in them, but the peasants do not seem to find it so, and even indulge in the “light fantastic” with considerable grace and freedom of motion.

Their chief objection, however, is the noise they make. Having lived for some time in the close vicinity of a public school in Brittany, where some one or two hundred children were in daily attendance, wearing these wooden sabots, I have a very distinct recollection of the din and clatter these little ones would make, as they raced each other down the hill on their release from school. Not many years ago an attempt was made to introduce wooden shoes into the United States, but it met with so little success that its projectors were forced to abandon the scheme.

* * * * *

In Venice we find that the custom in olden times was to have the shoes of the women mounted very high, so as to make walking as difficult as possible. By this means jealous husbands thought they would be able to keep their wives at home; but the plan did not succeed very well, I believe.

Figs. 17 and 18 show the Venetian shoes of this period, the sixteenth century. The first one, of white leather, is cut out in a delicate lace-work pattern, furnished with a broad sole, and would have been comfortable enough, were it not for its high support.

[Illustration:

Fig. 25.

Fig. 26.

Fig. 27.]

These supports, or _chapineys_, as they were called by the Venetians, were made of wood and covered with leather of different colors. Many were curiously painted, while the richest were of gilt. The height of these _chapineys_ was determined by the rank of the wearer, the noblest ladies often having them one-half yard or more high. Of course no woman could walk easily, hampered with such appendages, so all that could at all afford it would have one or two attendants to support them on either side when they walked abroad; and even thus supported, walking was extremely difficult.

Finally, the daughters of one of the Doges came to the conclusion that the fashion was abominable, and they would stand it no longer. It was not long before their suffering sisters became of the same mind, and the fashion gradually died out.

When Charles I. first met his future wife at Dover, he seemed surprised to find her so tall, and, having made some remark to that effect, she answered him as follows: “Sire, I stand upon my own feet. I have no help of art. Thus high I am; I am neither higher or lower,” wishing him to understand, it seems, that her fine stature was not due to artificial means.

Fig. 15 represents a highly ornamented clog of this period, while Figure 19 shows another style of Venetian pattern.

[Illustration:

Fig. 28.

Fig. 29.

Fig. 30.]

On page 13 we have two shoes from Africa, Figs. 21 and 22. The first, of yellow leather, is quite simple in design, but the latter is more elaborate in decoration. Fig. 24 shows an Indian shoe, while Fig. 23 is a Persian boot, whose pointed front is supposed to have been designed for the purpose of preventing the wearer from kicking up the dust, so unpleasant in hot countries.

* * * * *

In France the clothing of the foot has always been a subject of special consideration, and many have been the styles that have emanated from there. Among the first was the long pointed shoe, called the _poulaine_ (Fig. 25), in England named _crakowes_. (This name, _poulaine_, seems to indicate that the fashion came from Poland, though the pointed shoe is supposed to be of Eastern origin.) These shoes grew both in favor and length, for a number of years, until the _poulaine_ had reached such proportions that it was necessary to fasten it to the knee by means of a chain of gold or silver, while in order to keep it in shape it had to be stuffed with hay, straw, or fine moss. The length of the _poulaine_ was determined in the same manner as the height of the _chapineys_, by the rank of the wearer, and it was no uncommon sight to find a nobleman with his _poulaine_ some twelve inches or more in extent, while the upper part of his shoes would be cut out to imitate the windows of a church.

[Illustration:

Fig. 31.

Fig. 32.

Fig. 33.]

When the crusading army was before Nicopolis, these _poulaines_ astonished the Turks very much, who probably wondered how fighting was to be done in them. When it came to decisive action, however, it was found that the _poulaines_ impeded the movements of the knights so much that an order was given to cut them off.

There was also made, at this time, in order to avoid trailing the _poulaines_ in the mud of the narrow streets, a kind of wooden clog (Fig. 27), with cross-bars edged with iron; this was fastened to the foot by an embroidered leather strap. By means of this contrivance the _poulaines_ were kept from contact with the ground.

This fashion flourished for a long time despite the anathemas of the bishops, who stigmatized them as immoral, and the denunciations of officials.

By an act of Parliament, in 1463 shoemakers were prohibited from making, for the lower classes, shoes with points more than two inches long; and afterwards excommunication was pronounced on any person found wearing them; so they were forced to retire, after a vigorous reign of almost three centuries.

From the _poulaine_, fashion ran into the opposite extreme, and in the sixteenth century people wore shoes with square toes as broad, and sometimes broader, than they were long (Fig. 26). They had no straps, and were only held on the foot by the narrow piece rising above the heel. It was shoes of this kind that were worn by Francis I. of France, and Henry VIII. of England.

[Illustration:

Fig. 34.

Fig. 35.

Fig. 36.]

In the latter country they were abolished during the reign of Mary Tudor. The examples given are believed to be German, and must have belonged to a person of high rank, from their decoration.

Another early example of a French shoe is Fig. 29. It is of white stuff ornamented on the instep with a large rosette of silver lace and a long metal point. The heel is so high that the wearer must have literally walked on her toes. Another female shoe of interest is from the wardrobe of Catherine de Medicis, Fig. 28. The shoe, of white leather, no longer has the toe pointed but is square in shape, covered to the instep with silk, on which are worked figures in silver lace, giving to it the appearance of a metal surface. This shoe is peculiar, in having a sole which connects the toe and heel together in the form of a pattern.

Fig. 30 shows a shoe of this period, of delicate workmanship. The toe has now become quite round, while the leather is slashed to show the stocking underneath.

Fig. 31 represents an Italian shoe of the seventeenth century; Fig. 33 is another style of the peaked shoe, of the same date. Fig. 32 is thought to be Flemish in origin, and of the eighteenth century. The heel and back are not unlike in shape the shoe worn during the Regency in France, but the peculiar front-piece makes us think that this shoe could never have been very popular for every-day

wear.

[Illustration:

Fig. 37.

Fig. 38.

Fig. 39.]

During the Revolution in France, there was quite a mania for classic styles in shoes, and many ladies in high society adopted the Greek and Roman sandals, which were fastened on the foot by gay-colored ribbons. Mme. Tallien once appeared at a ball in such sandals, with her toes decorated with diamond rings.

Fig. 34 shows the shoe of the unfortunate Duke de Montmorency, a victim of the relentless animosity of Richelieu. It is of black leather, with a large red heel, and entirely covered with ornaments; tradition says it was gathered on the scaffold. Fig. 35 represents a highly ornamented lady's shoe of this period, while Fig. 36 is a shoe worn during the Regency. The heel is very high and not unlike a barber's wig-stand; the front, however, is rather graceful in shape.

Figs. 37 and 38 are samples of the curiously carved wooden shoes which were worn by ladies at the end of the sixteenth century. Fig. 39 represents a black leather shoe of Louis XIV., with red heel; these were in high favor at court at this time.

* * * * *

[Illustration:

Fig. 40.

Fig. 41.

Fig. 42.]

The use of boots marks a conquering race. In Germany, during the Middle Ages, serfs were forbidden to wear them; and this probably explains why, when they rose for justice, after ages of oppression, they chose for their standard a great peasant's shoe. The samples of boots given are from the time of Louis XIV. and XV. Fig. 40 was called the cauldron boot; this had a peculiar appendage around the ankle. Fig. 41, the bellows boot, has an enormous top, so that a man could hardly wear a pair without straddling. Fig. 42, the postillion's boot; these were generally made of very heavy material, so if the postillion, by chance, should fall from his horse, the wheels of the carriage might pass over his legs without doing him any injury.

* * * * *

We have now followed the various changes that shoes have undergone from the earliest times to the present, and would bring our remarks to a close with a notice of some of the shoes of to-day furnished by J. & J. Slater, which, if not as fantastic in shape as some that we have treated, cannot be excelled for grace or durability.

Fig. 43 is a Ladies' Riding Boot, made of morocco and patent-leather. This style is the only correct one at present, and no riding costume is complete without them.

Fig. 44 represents Ladies' Button Boot. The material employed is kid top, with patent-leather foxing. This makes not only a very stylish but comfortable walking boot.

Fig. 45 shows Ladies' Toilet Slipper. It is made of Suéde kid lined with silk. This material is now the latest style for dress or toilet slippers.

[Illustration:

Fig. 43.

Fig. 44.]

Fig. 46 shows Ladies' Oxfords, made of French kid, with patent-leather tips. This is a delightful summer walking shoe, either for city or country wear.

Fig. 47 is a Gentleman's Riding Boot, the only proper boot for park riding.

Fig. 48, Gentleman's Button Boot, made with kid top, calf foxing, with tips, for walking, or cloth tops and patent-leather foxing, for dress wear.

Fig. 49, Gentleman's Oxfords, or summer walking shoe; very easy and comfortable for every-day wear.

The above are but a few of the various styles introduced by them, and a visit to their establishment will convince all of the high reputation their goods have achieved in the last twenty-five years.

* * * * *

Shoes have not only been used for their natural purpose of covering the feet, but from remote time have played a part in many of the important actions of life. Years ago it was the custom in Ireland to elect a person to a certain office by throwing an old shoe over his head. But on one occasion an excited elector, whose place it was to throw the shoe, aimed too low, so that the shoe hit the candidate on the head, instantly killing him. After this occurrence the practice fell into disrepute.

[Illustration:

Fig. 45.

Fig. 46.]

In England it was once customary to bind contracts by the exchange of old shoes, while we are all familiar with the practice of throwing an old shoe after a bride for good luck; but I wonder how many know what it originally signified. It is a custom that has come to us from the Saxons, and with them denoted that the authority under which the bride lived while in her father's home was now delivered over to the husband, who was privileged to exact implicit obedience from his wife.

* * * * *

Shoes have also had their share of superstition attached to them, it being considered to portend great evil, if by chance one should put the right shoe on the left foot, or _vice versa_. Even one of the Roman Emperors is said to have run the greatest risk from just this cause alone.

"Augustus having by o'ersight, Put on his left shoe for his right, Had like to have been slain that day, By soldiers mutinying for their pay."

But in this day of button shoes the dangers to be incurred from this cause are very slight.

A SHORT TREATISE

ON

* HEAD * WEAR *

ANCIENT AND MODERN,

ILLUSTRATED BY

Walter H. Goater.

Head Wear, Ancient and Modern.

Tracing the history of man as far back as we can under civilized conditions of life, we find that in one form or another he has made use of some artificial contrivance to protect his head.

Nature, in her bounty, seems to have provided in part against the necessity of the hat, by giving to the head a thick and abundant covering of hair, but, instead of considering this as an indication that the head required no other protection, mankind seems rather to have regarded it as a hint to keep this most important part of the body well covered.

The hat being the most conspicuous article of dress, and surmounting all the rest, it is only natural to find that from the earliest times special care and attention has been given to its adornment—showy plumes, rare jewels and rich bands of gold and silver being used at different periods to decorate it.

Its form and frequently its color have also been made to designate the rank and character of the wearer: As the Monarch by his crown, the Cardinal by his red hat, which betokens his readiness to spill his blood at any time for the sake of Christ, and the court fool by his cap with bells. In one form it serves to designate the military officer, in another the peaceful Quaker or the quiet man of letters.

[Illustration:

Fig 1. _Fig 2._ _Fig 3._ _Fig 4._ _Fig 5._ _Fig 6._ _Fig 7._]

The materials employed in the manufacture of hats have been various, stuffs of every kind and color having entered into their composition. The birds have been robbed of their brilliant plumage, the beasts of the field of their wool and hair. Amphibious creatures have yielded their fur, while the mines of the earth have given up precious metals and stones. All these have been used by man to make a suitable covering for his august head. Felt hats are by far the most ancient, silk hats being of quite recent introduction. They were known in Florence about a century ago, but were not introduced into France until 1825.

Tradition ascribes the discovery of felting to St. Clement. It occurred in this manner: While on one of his charity missions, becoming weary and foot-sore, he took off his sandals to ease his feet, which were all bruised from long walking over rough roads. While resting by the wayside an opportunity was afforded him of rescuing a little lamb from the cruel clutches of a wily fox that was pursuing it. The grateful little creature jumped round him and licked his hand for joy, and it was in fondling it that St. Clement observed some loose wool, which he gathered.

While carelessly handling it the thought suddenly struck him that it would be good to bind up the wounds on his feet with. No sooner was it thought than done, and he found it so soothing that he immediately resumed his journey.

[Illustration:

Fig 8. _Fig 9._ _Fig 10._ _Fig 11._ _Fig 12._ _Fig 13._ _Fig 14._ _Fig 15._]

At night when he came to remove his sandals he was surprised to find, instead of fine, soft wool, a piece of cloth, so firm and thick that he could not pull it apart. This was called felt, and St. Clement was made the patron saint of the craft. (However, it is only fair to state that, according to some authorities, there is abundant evidence to show that felting was known to the ancients long before the time of St. Clement or the Christian era.)

* * * * *

The most ancient form of head wear we find to be the cap such as is seen on figures representing the goddess of liberty. Hoods, also, of various shapes, date back long before hats appeared, the latter for a long time only being employed as an article of extra clothing in winter, worn over the hood or when going on a journey.

* * * * *

Among the ancient Egyptians very peculiar shaped caps were worn, like from Figures 1 to 7. Some of them would rise to a great height above the head, and then descend very low upon the chest in the shape of lappets. Those of the priests and of their attendants were often loaded with a profusion of symbolical decorations, composed of feathers, lotus leaves and other natural products.

In religious processions it was common to wear masks that covered the whole head and neck down to the shoulders. These represented the heads and busts of various sacred animals, such as the ibis, hawk, bull, dog and ram.

* * * * *

[Illustration:

Fig 16. _Fig 17._ _Fig 18._ _Figs 19 & 20._ _Fig 21._ _Fig 22._ _Fig 23._]

Our modern hat can be traced back to the _pileus_ worn by the ancient Greeks when on a journey. Hats with brims were also worn by them, though some authorities claim that the Greek citizen of mature years never wore a head-covering, it being confined to youths, workmen and slaves. The _pileus_ was a closely-fitting woolen skull-cap, which was sometimes worn as a lining to the helmet. It was adopted by the Romans at their public games and festivals by those who had once been slaves, and by the aged and infirm for sake of warmth.

From ancient coins and medals we find that the Romans went bareheaded, except at sacred rites, games, festivals, and when at war.

Baldness was looked upon by them as a great deformity, and Cæsar, mighty conqueror though he was, yet could not make nature add one single hair to his very scanty supply, is said to have prized the honor of wearing a laurel crown above all the other dignities conferred upon him by the senate, as it served to conceal his weakness.

In the city, to screen themselves from the heat, rain or wind, the Romans frequently threw the folds of their robe over their heads, but if they met any one to whom they owed respect, they immediately let the folds drop and remained bareheaded.

Figs. 10 and 12 are specimens of ancient Greek helmets, while Fig. 11 represents a young warrior equipped for battle. Fig. 8 shows the _petasus_, not greatly unlike our tennis hat of to-day. Fig. 14 is the Phrygian bonnet, which held its own for so many centuries.

* * * * *

[Illustration:

Fig 24. _Fig 25._ _Fig 26._ _Fig 27._ _Fig 28._ _Fig 29._ _Fig 30._]

The inhabitants of Eastern nations always have their heads covered. In China the men wear hats in shape and size resembling large umbrellas, like Figs. 18 and 23, or else small conical caps similar to Fig. 17. These are made of beautifully wrought cane-work and often have pictures of birds and flowers painted upon them. They also have another cap, which though richer in material is not so graceful. It is similar in shape to Fig. 22, made of black velvet with a blue silk centre and a red tassel surmounting the top. The distinctive mark of different ranks among the mandarins consists in the color and value of the button worn on the cap. Figs. 19 and 20 show the peculiar head-dress worn by the Japanese when going forth to battle. In Arabia, notwithstanding the heat of the climate, the men wear a most preposterous head-dress. Frequently fifteen cloth or linen caps are worn one over the other, the upper one being gorgeously embroidered in gold with a sentence from the Koran worked upon it. Not satisfied with this curious coiffure they add to it by wrapping around the outer cap a large piece of muslin ornamented at the ends with silk or golden fringe, which stream loosely on the shoulders.

A plume of white heron’s feathers is the distinctive badge of a chief among the Uzbek Tartars.

Throughout the East the turban is generally worn, its height being a mark to denote the rank of the wearer. In color it is generally of the most brilliant hue, and of richly embroidered materials. Great taste and ingenuity are exercised in the manner of twisting it around the head so as to make the folds appear as graceful as possible. The different turbans on page 9 give some idea of the various shapes they can be made to assume.

Emirs or Sharifs, descendants of Mohammed’s daughter, are alone allowed the high honor of adorning their heads with green turbans.

[Illustration:

Fig 31. _Fig 32._ _Fig 33._ _Fig 34._ _Fig 35._ _Fig 36._]

On page 11 we have some types of African head-dress, Figs. 31, 32 and 34 showing what the natives of that dark continent have done for themselves in the way of head adornment, entirely unaided by fashion or the knowledge of what their brothers in other parts of the world were wearing. Fig. 33, though of Asiatic origin and finer workmanship, is quite as grotesque in design as anything the wild tribes of Africa could devise.

At one time the Turks had a law by which none but themselves could wear turbans of rich texture. Their Greek subjects were condemned to wear dark cotton caps as a mark of their servitude. Armenians were compelled to appear in ridiculous-looking balloon-shaped caps, while the Jews were only permitted to wear brimless caps resembling inverted flower-pots. Later on, the Sultan issued a decree that all of his subjects should wear a red fez instead of their turbans. This law was received with the most determined and indignant opposition. So obnoxious to their feelings was this change, that the discontented party set fire to the houses of all those who favored it, and though finally the Sultan’s wishes passed into a law, it was years before many of his subjects became reconciled to it. Fig. 40 shows a turban worn by one of the Sultans; Fig. 41, the fez of the people. Figs. 37, 38, 42 and 43 on the same page are samples of Russian hats. In some parts of that country the head-covering of the people is made of birch bark and plaited grasses; but fur is the material most commonly used. The prevailing male head-dress of the inhabitants of Asia Minor appears to be the Phrygian bonnet, of which the characteristic features with them are its point on top, bent forward, and its long flaps descending on the shoulders. This style of hat was worn for many centuries, and traveled as far west as Venice, where the Doge always wore one.

* * * * *

[Illustration:

Fig 37. _Fig 38._ _Fig 39._ _Fig 40._ _Fig 41._ _Fig 42._ _Fig 43._]

As a part of defensive armor the hat became the helmet, which has changed but little in shape from the earliest times. Very elaborate and fantastic were some of the early forms, with their double or two-story heads, Figs. 46 and 47, to give the impression of increased height. The workmanship, also, was very beautiful, some of the ancient helmets being entirely covered with chasing

and designs of the most intricate character. With the Greeks and Romans the subject of armor was one of importance, and from their ancient monuments we can learn much of their form and beauty. Page 15 shows several kinds of helmets worn during the middle ages.

* * * * *

In Spain serious disturbances took place in Madrid in the eighteenth century over an attempt being made to banish the _sombrero_. While in other countries the fashion of hats has been undergoing changes, in Spain the same shapes are worn year after year, with but little modification. Page 19, with the exception of Figs. 52 and 53, which are Mexican, show several forms of Spanish hats. Fig. 51 is the style commonly worn by the priests when traveling about.

Page 21 gives some German types; Fig. 61 is the hat of a judge; Figs. 58, 60 and 62 are military hats, while Fig. 63 shows a Teutonic fool's cap decorated with bells.

* * * * *

[Illustration:

Fig 44. _Fig 45._ _Fig 46._ _Fig 47._ _Fig 48._ _Fig 49._]

In France the clothing of the head has long been a subject of special consideration, and many have been the styles that have emanated from there. At first, as in most of the other countries mentioned, hoods were worn, but when Charles VII. made his triumphal entry into Rouen, in 1449, he wore a hat lined with red velvet and surmounted with a rich plume of feathers. From this date hats and caps became general throughout France.

A curious appendage that was worn with the hat for many years was like Fig. 66, consisting of a piece of black stuff which was fastened to one side of the hat, the other end being thrown over the left shoulder. This band was often held in the hand and the hat allowed to fall off from the head and rest on the back.

Another peculiar head-dress was the Capuchin hood, Fig. 68. This had a long pointed tail that hung down the back, and in front was buttoned close up to the chin. Some gallants twisted the tails into all sorts of fantastic forms and carelessly poised them on the top of the head. With the shaven faces that were always worn with this hood, the men all looked very much like monks. It was fear of this appearance that induced Francis I. to set the fashion of velvet caps in his kingdom. Fig. 67 represents a French military hat. For the past fifty years the high silk hat has been the most popular style in France.

At one time there was a law in France which compelled all bankrupt Jews to wear a green hat, so that people might avoid losses by trading with them. The slang expression "Do you see anything green about me," is said to have derived its origin from this circumstance.

* * * * *

[Illustration:

RUSSIAN. PRINCE OF WALES. ** FRENCH. POPE'S TIARA. ** ENGLISH. ** SULTAN'S TIARA. DUKE'S. ** AUSTRIA. GERMAN.]

The early Anglo-Saxons for years wore no other covering for their heads than their long flowing hair, which they sedulously cultivated. When they did take to a covering, about the eighth century, it was in the form of a cap made most likely from the undressed skin of animals. The Britons, at the time of the invasion of Cæsar, wore on their heads a conical hat, which derived its name from the cabin or hut in which they lived, it strongly resembling it in shape. Helmets, with a projecting piece in front called a nasal, were worn by the early Briton warriors. The nasal was afterward discarded, as it was found to afford too convenient a hold to the enemy of the wearer, Stephen, at the siege of Lincoln, having been seized by the nasal of his helmet and held a prisoner.

It was not until after the Norman conquest that the use of hats became general in England. "A hatte of bever" was worn by some one of the nobles met at Clarendon about the middle of the twelfth century, and in the "Canterbury Tales" we hear mention of the merchant wearing on his head a "Flaunderish bever hat."

In the fourteenth century we find a very peculiar kind of head-gear popular in England, Figs. 70 and 72. First, on the head is a close-fitting skull-cap, which is encircled by a roll of cloth, flat like a band, or twisted turban-wise. Above is another piece of cloth,

cut and clipped around the edges in all manner of queer shapes, the whole falling around the head in a confused manner. Such hoods were worn by the ancient Knights of the Garter, and are said to have been borrowed from Italy.

It is in this same century that for the first time in England we find a feather in the hat, Fig. 75. It was stuck in perfectly straight in front, as they had not as yet acquired any grace in its adjustment.

[Illustration:

Fig 50. _Fig 51._ _Fig 52._ _Fig 53._ _Fig 54._ _Fig 55._ _Fig 56._]

During the reign of Queen Elizabeth a great variety of hats and caps were worn. They were mostly made of velvet and richly decorated with jewels, bands of gold or silver lace and feathers. A writer of that time describes them thus: “They wear them sharpe on the crowne, peaking up like the speare or shaft of a steeple, standing a quarter of a yard above the crowne of the head. Some others are flatte and broade on the crowne like the battlements of a house. Another sort have round corners, sometimes with one sort of band, sometimes another; now black, now white, now russet, now red, now green, now yellow, now this, now that—never content with one color or fashion two days to an end; and thus they spend the Lord’s treasure consuming their golden years and silver days in wickedness and sin.” Those must have been glorious days for the hatter when the fashions changed so rapidly that men were obliged to buy a new hat every two or three days.

During this same reign laws were made compelling the lower classes to wear on the Sabbath a cap of peculiar shape and make.

The escape of Lord Nithsdale from the Tower, in the early part of the eighteenth century, was principally effected by the large riding-hoods worn at that time, which he put on, along with his wife’s dress and cloak. Such hoods were ever after called Nithsdales.

On page 25 are pictures of some of the early forms of English hats. Figs. 76 and 78 belonged to the clergy. Fig. 77 is a Scottish bonnet.

* * * * *

[Illustration:

Fig 57. _Fig 58._ _Fig 59._ _Fig 60._ _Fig 61._ _Fig 62._ _Fig 63._]

The Puritans discarded all ornament of any kind from their dress and wore the steeple hat, high and narrow in the crown, with a broad brim (Fig. 83). The Cavalier of the same era wore a low, broad-crowned hat with a feather stuck on one side. The principal changes that have taken place in hats from time to time have been in the height of the crown and in the width of the brim. As this latter became wider it led to the device of looping it up, and thus originated the cocked hat that was worn during the eighteenth century.

To all Americans this hat brings patriotic recollections of revolutionary days—for Washington and his generals all wore cocked hats. On page 27, Fig. 85, we have the hat of the “Minute Man.” Also one worn, Fig. 79, during the good old Knickerbocker days. Fig. 84 shows the style of hat worn by Kossuth when on a visit to this country in 1851. Previous to this time the only hat made for gentlemen was the high silk hat and cloth caps for boys, but a few weeks after Kossuth’s appearance in the country thousands of hats similar to his were sold, the demand for them being universal. Since then soft and stiff felt hats have been brought to perfection in quality and style in this country far superior to any made abroad. This was shown in our Centennial Exhibition, in 1876, by Dunlap & Co. receiving the first prize for their productions over all competition of foreign and domestic manufactures. Figs. 86, 87, 88 are three different styles of high hats worn about fifty years ago. In the latter part of the eighteenth century the gaudy ornaments of lace, jewels, feathers, &c., gradually began to disappear from hats, giving place to the sober black band and simple buckle, and when that, too, had its day and passed away, the hats of men were left without any ornament, but in much better taste and more in keeping with their use than were those of old.

[Illustration:

Fig 64. _Fig 65._ _Fig 66._ _Fig 67._ _Fig 68._ _Fig 69._]

Hats have not only been used for the practical purpose of covering the head, but from remote time have played their part in many important actions in life. Among the Romans the hat was the symbol of liberty, and slaves were presented with one on receiving

their freedom. The Quaker hat dates from the origin of the sect in the middle of the seventeenth century, Fig. 80. After the assassination of Cæsar coins were issued by Brutus and Cassius, on which was represented a cap between two daggers. Even at a later period the hat or cap was identified with liberty as in the republic of the Netherlands. After the emancipation from Spain a hat became their national emblem, while we all know the part Gessler's hat played in gaining for the Swiss their freedom. The common practice of doffing the hat when meeting a friend is thought to be a modification of the ancient custom of unclothing some part of the body when in the presence of one to whom respect was due.

Many persons profess that from the dress alone they can give you a true estimate of the character of the man.

While this is, perhaps, expressing it rather strongly, it is certainly true that the material and style of one's dress does, to a large degree, denote the wearer's character; and especially is this so of hats and the manner in which they are worn.

[Illustration:

Fig 70. _Fig 71._ _Fig 72._ _Fig 73._ _Fig 74._ _Fig 75._ _Fig 76._ _Fig 77._ _Fig 78._]

The man of refined tastes will always be found to be very fastidious in regard to his head wear, buying only the finest quality of hat, while a coarse nature will be satisfied with a cheap slouch hat. The prosperous business man also can generally be picked out by his hat, it being something substantial and good of its kind, while the man of mean and parsimonious habits will usually have a hat to correspond with his dwarfed nature.

"Have a good hat; the secret of your looks Lives with the beaver in Canadian brooks; Virtue may flourish in an old cravat, But man and nature scorn the shocking hat."

[Illustration:

Fig 79. _Fig 80._ _Fig 81._ _Fig 82._ _Fig 83._ _Fig 84._ _Fig 85._ _Fig 86._ _Fig 87._ _Fig 88._]

We have now followed a few of the changes that hats have undergone from the earliest times to the present, and would bring our remarks to a close with a notice of the house of R. Dunlap & Co., which was founded by Mr. Robert Dunlap in 1857, who opened a small store November 14, at 557 Broadway, between Spring and Prince streets, and by originality of designs and selling the finest class of hats, he soon became the popular hatter of the city. Two years later, in 1859, Mr. Paran Stevens, the Napoleon of hotel-keepers, induced Mr. Dunlap to occupy a store under the Fifth Avenue Hotel, which was just then completed, and who desired only those as tenants who sold the best goods in their line. At this time the hotel, situated at the corner of Twenty-third street and Fifth avenue, was considered very far up town, and it was predicted that Dunlap's venture would be a failure; but the young and enterprising hatter soon became the leading hatter of the country. The firm remained there for twelve years, and then removed to their present location, at 178 and 180 Fifth avenue. Finding the demand for their hats increasing from the residents of Brooklyn, Jersey City and surrounding suburbs, in 1876 they moved their store from 557 to 179 Broadway, near Cortlandt street, as their down-town store.

The popularity of the Dunlap hat induced the firm to increase their manufacturing facilities by the erection of a large factory on Seventh avenue, New York, where all the silk and opera hats are made, and a straw-hat factory at 132 and 134 South Fifth avenue, New York, and also the erection of one of the largest and most complete felt hat factories in this country at the corner of Park and Nostrand avenues, Brooklyn.

The growing demand for these hats in the West induced the firm to open a branch store under the Palmer House, Chicago, about three years ago, which has proved a grand success; also, quite recently, they have opened an elegant store on Chestnut street, Philadelphia. Besides their own stores in New York, Chicago and Philadelphia, their celebrated hats are sold by authorized agents in all the principal cities of the United States, where the patrons of the Dunlap hat can purchase their hats of the same style, quality and price as sold by them in their own stores.

Bibliography 188

INTRODUCTION

The conception of this “Story of Milk” dates many years back. In his life-long study of problems connected with dairy farming and milk industries in two of the world’s greatest dairy countries, Denmark and the United States, the author has felt the need of a concise handbook covering this interesting subject. In his forty years of work in the manufacture and distribution of dairy and milk-food preparations he has been brought constantly into contact with men and women interested in the production of milk and has found a persistent demand for a book that might be consulted by anybody in regard to questions related to these greatest of all foods, which are, or ought to be, a most important part of the daily diet of children and adults alike, at all times, everywhere.

There was a time during the war when, frightened by the soaring of the price which had remained remarkably low for many years, much too low in fact compared with the cost of other food, people began to cut down the consumption of milk to an alarming extent. Even the National Food Administration for a short time recommended saving in the wrong place, forgetting that, at the highest figures reached during the temporary shortage, milk was still one of the cheapest of foods and that it was absolutely indispensable for growing children and exceedingly beneficial for men and women who were called upon to exercise their physical and mental powers as never before. But with men like Dean Russell of the Wisconsin Agricultural College in the Department and Dr. Graham Lusk of Cornell University representing the United States on the Inter-Allied Council of Alimentation, the Food Administration could not long maintain this mistaken attitude but quickly joined the College authorities and the representatives of the dairy industry in

advocating a liberal use of milk. And the Department of Agriculture sent out over the country a large force of demonstrators to show the people how to use milk in making cottage cheese and many other ways, and Agricultural Colleges, Farm Bureaus and Home Economics Agents worked hand in hand with Washington in disseminating the knowledge of handling and utilizing milk.

A genuine interest has been aroused in our country in the economy and conservation of food, and in “The Story of Milk” the author hopes to place at the disposal of the student of Domestic Science a comprehensive book of reference which may open the eyes of many to the fact that there is no more interesting subject than “Milk” in connection with the study of the welfare and physical improvement of humanity, and that milk and its products should be used to a much greater extent than heretofore.

It would make a long list of references if the author should mention the sources on which he has drawn for information beyond his own life-long experience in the dairy and related industries. He desires to express his sincere appreciation of the kindness and ready response of institutions and friends to whom he has appealed for photographs and cuts which have enabled him to illustrate the text so liberally. In the back of the book will be found a brief bibliography of standard dairy literature in which students may find material for further information.

Many interesting data and several excellent illustrations have been obtained from the bulletins and collections of the Department of Agriculture in Washington and the Dairy Schools at Ithaca, N.Y., Madison, Wis., and Ames, Ia.

The Chapter on Milk Cookery was written and classified by the author’s wife, whose practical experience will make it useful alike to housekeepers and students of Domestic Science.

J. D. FREDERIKSEN.

Little Falls, N.Y.,

April, 1919.

HISTORICAL

Milk and its products have been known and used from time immemorial. In the Bible milk and milk foods are mentioned in some thirty places. In Gen. 18:8 we read: “... and he (Abraham’s servant) took butter and milk and set it before them ...”; 1 Sam. 17:28: “And Jesse said unto David, his son: ... bring these ten cheeses unto the captain of their thousand and look how thy brethren fare....”; Prov. 30:33: “For the churning of milk bringeth forth butter,” etc.

Though in some of these passages butter is mentioned it is hardly probably that this product was really made or used at the time under the climatic conditions in Palestine. More likely it was various kinds of curd and cheese which the translator called butter. At any rate, the Hebrews of that far-off day coveted milk and its products among their most valued foods. From Egyptian, Greek and Roman history it appears that knowledge of cheese goes back to the most ancient times and that it was made from the milk of sheep, goats, cows, asses, mares, in fact from all domestic animals; in the far North, Lapps and Eskimos still make it from the milk of the reindeer, the Arabs use camel’s milk, Llama cheese is famous in the Cordilleras and Zebu cheese in Ceylon and India.

Even in ancient times the great food value of dairy products was recognized. Plinius tells of Zoroaster that for twenty years he lived exclusively on cheese, and Plutarch calls cheese one of the most nourishing of foods.

As time went by, the cow excelled all other domestic animals in capacity for the production of milk and by constant use through centuries for the one special purpose,—by care in feeding, breeding and selection,—special breeds of cattle were developed which gave milk in extraordinarily large quantities.

[Illustration:

[Illustration:

Thomas R. Segelcke, father of scientific dairying in Denmark]

[Illustration:

L. B. Arnold, noted dairy expert and writer, of Herkimer County, N.Y.]

In the cold climate of the northern countries where butter will keep for a long time it has been made for centuries. The illustration above is from a mural painting in an old church in Finland. Evidently at the time when that was built the devil already played havoc with the churn and even up to the days of our grand-fathers his Satanic Majesty was often accused of preventing the butter from "coming."

Not until the middle of the nineteenth century did dairying take its place among the important industries of the world and science begin to be applied in its development. Between 1860 and 1870 Thomas R. Segelcke, the "Father of Scientific Dairying" in Denmark, introduced the thermometer in churning instead of the rule of thumb and started the keeping of records in the manufacture of butter. N. J. Fjord started a series of experiments in the creameries, continued through the next decades, and which became models for similar work throughout the world, covering pasteurization, ice houses and cold storage, comparison between various systems for raising the cream, separators, feeding rations, etc., and Denmark developed its agriculture and dairy industry to an enviable position. About the same time Dr. Schatzman applied scientific methods in cheese making in Switzerland and Jesse Williams started the first American cheese factory near Rome, N.Y., while L. B. Arnold, X. A. Willard, Harris Lewis, Harry Burrell and many other progressive dairymen made Herkimer County cheese famous.

From New York, dairy farming spread rapidly westward through Ohio to Michigan and Northern Illinois, where butter making was developed around Elgin, and to Wisconsin, where Governor Hoard preached the gospel of progress, Babcock invented and gave to the world the famous test that bears his name and Russell made a specialty of dairy bacteriology.

[Illustration:

[Illustration:

Governor W. D. Hoard, of Wisconsin, promotor of progressive methods of dairying]

[Illustration:

J. A. Ruddick, Dairy Commissioner of Canada]

J. H. Monrad, Assistant Dairy Commissioner of Illinois, student, writer and lecturer on dairy subjects, collected and indexed one of the most complete and valuable libraries of dairy literature found anywhere, which after his death in 1915 was taken over and installed in special rooms by Chr. Hansen's Laboratorium in Copenhagen, where a librarian is keeping it up to date and it is open to the public.

In Canada, Dairy Commissioners Jas. W. Robertson and J. A. Ruddick, D. M. McPherson, the "Cheese King," and others contributed to an enormous development of the manufacture of high-class cheese, and in New Zealand and Australia similar progress was made.

Business and science have vied with each other in increasing the output of dairy products and improving their quality. In the table below, showing estimates for 1917, some interesting figures are given of the amount of milk produced in the United States and the uses to which it is applied.[1]

Uses to which milk is put (calculations based on estimates)

■■■

Although the table accounts for all the milk produced, it does not tell the whole story, since the preparation of a number of products results in the formation of vast quantities of by-products that are not used to the fullest advantage for human food.

New York City alone consumes 1,600,000 quarts of milk a day, but even this enormous quantity means only 0.6 pint per capita. The consuming public has been slow to realize the value of milk and its products, and too much emphasis cannot be laid upon the fact that even at the largely increased cost of all dairy products they are still some of the cheapest and the most healthful of foods, especially for growing children, and should be used in much larger quantities.

THE STORY OF MILK

THE STORY OF MILK

CHAPTER I

PRODUCTION, COMPOSITION AND CHARACTERISTICS OF MILK, MILK FERMENTS, PASTEURIZATION

DAIRY CATTLE

[Illustration:

Holstein]

A number of typical but widely different breeds of dairy cows have been developed in various dairy countries, each owing to the soil and the climatic conditions of its home, as well as to the skill and fancy of the breeders, its characteristic features, form, color, etc.

[Illustration:

Herd of pure-bred Holstein cows on a farm in central New York]

=Milk-Breeds.=—The black and white _Holstein-Friesians_ (which, by the way, had their home in Holland and not in Holstein) are known for their large production of not very rich milk, while the _Guernseys_ and _Jerseys_ give milk exceedingly rich in butter-fat. A good Holstein cow will give from 7,000 to 10,000 lbs. of milk in a year, containing from 3¼% to 4% butter-fat. Some of them produce as much as 20,000 to 30,000 lbs. in a year—nearly 4,000 gallons—just think of it! Jersey cows will usually not produce as much in quantity as the Holsteins but Jersey milk often contains 5% or 6% or more butter-fat, and a few of the best have been known to produce 800 to 900 lbs. of butter in one year, an amount equal to the cow's own weight. The red _Danish_ cow is an exceedingly good and highly bred milk producer which, however, has not been introduced in the United States, but the Scotch _Ayrshires_ and the _Brown Swiss_ are other well-known dairy breeds which are in favor with many American farmers.

[Illustration:

Guernsey]

But, alas! too many herds of dairy cattle average less than 5,000 lbs. of milk per cow per year and do not pay for their feed.

[Illustration:

Jersey cows]

[Illustration:

Red Danish]

[Illustration:

Ayrshire]

[Illustration:

Shorthorn, beef-strain]

Many native cows respond, however, to good care and feed and with a thoroughbred bull a satisfactory herd can readily be built up from carefully selected native stock. Such continued cross-breeding is more apt to succeed than attempts to cross two thoroughbred breeds because the characteristic features in full-blooded animals are so strong as to invariably predominate in the progeny over the less pronounced forms and tendencies inherent in native cows. But where two full-blooded animals are mated and the strong characteristics in each are fighting for predominance the result is apt to be a poor, ill-proportioned offspring as the result of atavism.

[Illustration:

Shorthorn, milk-strain]

=Beef-Cattle.=—Cattle bred and developed for the purpose of producing beef rather than milk are called by contrast beef-cattle. As examples of beef-cows look at the _Shorthorns_ or the _Herefords_ or the _Polled Angus_ at the next State Fair you visit and notice the square, deep, smooth body with muscles and fat strongly developed in contrast to the loosely built, bony milk-cow with its tendency to turn all its food into milk at the expense of the body. There are, however, also among the Shorthorns, strains of good milkers, but as a rule these beef-breeds are not selected for the dairy farm, and "dual purpose" cows are not usually profitable.

=Food and Water.=—The natural food for the dairy cow in summer is grass, and where rich, succulent grass and clover grow in abundance, as on the fertile meadows of Holland and the Channel Islands, or the Swiss Alps, the highly cultivated Danish farms, the eastern and middle-western states of America, etc., dairying early reached its highest development. As the value of milk and its products for human food became more generally recognized and all-the-year-round production was forced, it was found necessary to feed the cows heavily in winter too, not only hay, but also grain and succulent food such as beets and corn-ensilage (green corn cut, stalks, cobs and all, and packed in a silo), and science was taken into play to formulate _Balanced Rations_ containing the proper amounts and proportions of the various nutrients—Protein, Fat and Carbohydrates. It is not the place here to go deeper into this problem which has long been a subject for thorough research and experiments. In fact, more attention has been paid to the feeding of cattle than to the proper nourishment of human beings, and much of what we know about the latter has been deducted from experience and study on the dairy farm, and from laboratory work along that line. In the chapter on "Milk as a Food" we are taking up food values, etc., in relation to the feeding of children and men. Suffice it here to say that the same fundamental principles apply to the feeding of calves and cattle for the production of milk and beef. And we wish to emphasize the fact that, with due consideration to the proper proportion between the various groups of nutrients, it is much more important that the food is succulent, appetizing and easily digestible than that the ration shall be accurately balanced.

[Illustration:

Cutting ensilage and filling the silo]

This fact, long well known to practical breeders and dairymen, has recently been confirmed by Dr. E. V. McCullom to whose experiments further reference is made in the chapter on milk as a food for children. He shows that there is a very great difference in the quality of Protein and Fat from various sources and that there is "Something Unknown" in butter-fat, for instance, which is absent in most other fats and which is vital for the growth of the child as well as for the proper nourishment of man. This unknown but essential substance is also found, in small quantities, in the leaves of certain plants, as in alfalfa, while it is absent in the grain of the cereals.

[Illustration:

An abundant crop of alfalfa hay; cut three times during the summer. Supplies protein in the ration]

In modern dairy farming _alfalfa_ is considered an indispensable source for protein, and corn-ensilage or beets for carbohydrates, while bran, cottonseed meal or oil cake, malt-sprouts, gluten, distillers' grain, etc., may be used to advantage in various combinations.

[Illustration:

Cows milked with machine]

Contrary to a general impression one cannot feed fat into the milk. A large amount of oil cake or other food rich in fat in the daily ration does not increase the percentage of butter-fat in the milk. Rather, it depends largely upon the breed and to some extent upon the period of lactation. Provided the food agrees with her digestion and keeps the cow in a good, healthy condition, the composition of the milk is not changed to any appreciable extent by a change in make-up of the food.

It goes without saying that to produce from 20 to 50 lbs. of milk a day the cow must have an abundance of _fresh, pure water_ to drink and she should not have access to stagnant water.

=The Barn= must be clean, light and well ventilated and the cows should be milked with clean hands into a clean pail which is covered as far as possible so as to prevent dust from falling into the milk, or with one of the excellent milking machines which are now frequently used in large dairies. The milk is strained and cooled immediately after milking.

[Illustration:

Milking machine]

[Illustration:

In the partly covered milk-pail dust does not fall as readily as in the one entirely open]

=Milking.=—The cows are usually milked twice a day; occasionally, when the highest possible yield is desired, as in important tests, three or four times. The first five days after the birth of the calf the milk,—the Colostrum so called,—is not normal and should not be used for human consumption. It may be fed to the calf. The first three to four months the yield of milk generally is higher than later, when it gradually drops until after about ten months it stops altogether and the cow goes “dry” at least for some six weeks before dropping the next calf. The highest annual yield may be obtained by having the cows “come in” in the Fall or early Winter and feeding them well all Winter to keep up an abundant flow of milk. Then, when they come out on pasture in the Spring,—in the latitude of the Great Lakes about May 15th,—the fresh, rich feed will stimulate production and give it a fresh start so that the milk-pail may continue to be filled during the next few months and the shrinkage of the yield will not occur until the time when the pastures dry up. The cow will then go dry in the early Fall, when feed is scarce. Usually, however, the cows are allowed to “come in” in the Spring and the yield of milk begins to shrink in the late Summer with little or nothing in the Winter.

[Illustration:

Milking on a Danish farm]

=Test the Cows.=—To ascertain if a cow pays for her feed the amount and the quality of the milk should be tested and computed for the year. If the milk from each cow cannot be weighed every day it may be done regularly once a month or preferably oftener. If it is weighed morning and evening once every ten days it is easy to keep the account by multiplying the number of pounds by ten and adding the totals for the year. Occasionally the milk may be subjected to the Babcock Test to ascertain its richness; three or four times during the period of lactation is sufficient.

Where farmers do not have time to do the testing themselves they often combine and hire a young man or woman, trained in an agricultural college, to go around from farm to farm and do the work. These experts not only test the yield and the percentage of fat but also weigh and compute the feed so as to help the farmer make up his rations and calculate whether each cow pays for her feed or not. The members of these associations meet and compare notes and a friendly rivalry is stimulated which may do much toward increasing production. As a matter of fact, where Cow Test Associations have been introduced, both yield and quality of the milk have been largely increased.

[Illustration:

Dr. Bernhard Bang of Copenhagen, Denmark]

=Healthy Cows= alone can be depended upon to produce sanitary milk. In many herds of milk-cows tuberculosis is prevalent, and constant vigilance is necessary to prevent its spread. The _Tuberculin Test_ discovered by Koch is invaluable for the purpose of ascertaining the presence of tuberculosis. It is not necessary, however, to kill every infected animal. Only where the lungs or the udder is affected and a physical examination shows an advanced stage of the disease such radical means are advisable. When the tuberculin test was first introduced many valuable herds were wantonly and foolishly killed off because some of the highly

developed dairy cows showed reaction to the test while worthless scrubs were allowed to live and spread the disease. For only the intelligent and public-spirited owners of fine herds submitted their cows to the test, a reaction to which, under ill-advised regulations, permitted state officials to condemn the infected herds. In Denmark Dr. Bernhard Bang introduced a system of isolation of the infected animals which together with _Compulsory Pasteurization_ of the milk from such cows has proved efficient for the eradication of tuberculosis, and the _Bang Method_ is now generally recognized as the proper way of handling the matter.

COMPOSITION OF COW'S MILK

Cow's milk contains on an average in 100 lbs.:

87 lbs. of water 4 lbs. of butter-fat 3¼ lbs. of casein and albumin (protein) 5 lbs. of milk sugar ¾ lbs. of ash (mineral matter) 100 lbs. total.

It consists therefore of 87% water and 13% "solids," 4 of which are fat and 9, "solids—not fat." =Butter-Fat= is found in milk in the form of minute globules suspended in the liquid. As fat or oil is lighter than water (has less specific gravity) it naturally floats and the fat globules therefore soon rise to the top when milk stands at rest, forming a layer of _cream_ which may be skimmed off from the _milk_. In chemical composition butter-fat is very nearly the same as other animal and vegetable fats, but the slight variation may make a lot of difference in digestibility and palatability as well as in nutritive value, and it is a mistake to consider Oleomargarine, Butterine, Nut-Butter and other substitutes for butter "just as good" because a chemical analysis shows them to contain "almost" the same elements or compounds. These products may be good and legitimate if sold for what they are, but should never be allowed to be sold or served for what they are not, genuine butter.

[Illustration:

Composition of cow's milk]

=Casein and Albumin= are the proteids or nitrogenous matters of the milk, in chemical composition and in food value much the same as the protein in beans and peas or in meat, or the white of eggs. Casein is present in much larger quantity than albumin and is distinguished from the latter by being precipitated by rennet, which has no effect on albumin. Casein may also be precipitated by acids, while it required boiling as well as acidity to throw the albumin out of solution.

=Milk-Sugar= is related to the vegetable sugars, glucose, cane sugar, etc., and remains in solution in the whey which separates out from the cheese-curd when milk is curdled with rennet or acids. The whey also contains the mineral matters or _ash_, which consists largely of phosphate of lime, of use to the young in building up bones. When whey is boiled down to a thick syrup and left to stand, the sugar will crystallize out and may be separated from the liquid, still holding in solution the mineral matters.

[Illustration:

Fat globules as they appear under the microscope]

=Mineral Matters.=—These may be gathered as _ash_ by boiling off the water from this liquid or from the whole milk and burning the rest, as all the constituents except the ash belong to what in chemistry is called organic matter, which disappears in the air by burning.

[Illustration:

Dr. S. M. Babcock of Madison, Wis.]

HOW TO TEST MILK

Milk may be adulterated or decreased in value either by skimming or by watering. In either case the percentage of the most valuable constituent, the butter-fat, is diminished. It is upon this fact that the most practical test, the Babcock, is based.

[Illustration:

Babcock test outfit]

=The Babcock Test.=[2]—By treating a sample of milk with strong sulphuric acid the butter-fat is liberated as an oil. By subjecting the mixture to centrifugal force the light butter oil is separated from the rest of the milk and the percentage can be easily

determined. Centrifugal force had already been used in the Fjord Cream Test, but it remained for Dr. Babcock to work out the splendid practical and reliable test which bears his name and in which he has given to the world an invention of incalculable value.

[Illustration:

A two-bottle machine]

=Sampling.=—Whether it is new milk or skim milk or buttermilk or cream that is to be tested the first thing to observe is to take a _truly representative sample_. The liquid must be thoroughly mixed by pouring it several times from one vessel to another, or stirring vigorously.

It may not always be convenient to make a test immediately when the sample is taken. In the creamery where the milk is paid for according to its fat contents, samples are taken every day from every patron's milk and it would take too much time for the butter maker to test all of these samples before they would spoil. A preservative, corrosive sublimate,—poisonous but all right for the purpose,—is therefore added and all the samples of one farmer's milk for several days or a whole week are put together in one glass to be kept and tested at one time. This is called a composite test and has proven entirely satisfactory.

=The Lactometer= has been used to discover adulterations, depending upon the difference in specific gravity of the various constituents. The specific gravity of whole milk is about 1.032 which means that, if a certain volume of water weighs 1.000 weight units, the same volume of whole milk weighs 1.032, the same volume of butter-fat weighs, say, .900, or of cream about 1.000, and of skim milk 1.036 units. If the Lactometer shows a sample of milk to have a higher specific gravity than 1.032 it may therefore be suspected of having been skimmed. But it will readily be seen that by removing from whole milk some of the cream and adding water, the specific gravity can easily be brought back to normal for whole milk. This test is therefore unreliable and has been discarded with the advent of the Babcock.

[Illustration:

The acidemeter]

=Acidity Test.=[3]—The acidity, or sourness, of milk or cream, which depends upon the amount of lactic acid developed in it, may be tested by a liquid normal alkali or by the Farrington Alkaline Tablets, a solution of which added to sour milk neutralizes the acid. A few drops of an indicator, Phenolpthalein, added to the milk, turns it pink when all the acid has been neutralized, and the amount of alkali solution used shows the percentage of acid in the milk. This is quite important in preparing "starters" for ripening the cream in butter making or milk in cheese making, and in the manufacture of "Commercial Buttermilk," etc.

There are other tests used in scientific dairying as the _Fermentation Test_ to ascertain the relative purity of milk, the _Casein Test_, etc., but the above are those mostly used besides the _Bacterial Count_ which is mentioned under the chapter on "Milk Supply," and the _Rennet Test_ described under "Cheese Making."

FERMENTS

Two classes of ferments are of importance in connection with milk: (1) "unorganized" or chemical ferments, the "enzymes," and (2) "organized" ferments such as bacteria and yeast.

Enzymes

=Rennet.=—Among the unorganized ferments, _Rennet_ or _Rennin_ is highly important on account of its power of coagulating or curdling milk by precipitation of the casein. Rennet is extracted from the stomach of the suckling or milk-fed calf, where it serves in digesting the calf's food. It is in the market in the form of a liquid extract as well as a dry powder compressed into tablets (Rennet Tablets and Junket Tablets). The characteristics and use of rennet are described under "Cheese Making" in Chapter III.

=Pepsin= is another enzyme the office of which in the process of digestion is to dissolve albuminoids. It is not considered identical with rennet though in an acid solution it will curdle milk. It occurs in the stomachs of grown animals fed on solid food and is usually produced from hogs' stomachs.

Bacteria

Everywhere, in the air, in water, in the soil, and clinging to every object in the world, are minute organisms known under the common names of _bacteria_ or _microbes_. In contrast to rennet and the other “unorganized” ferments, bacteria belong to the “organized” class. Some are harmful, producing putrefaction, dissolution, poisons or disease; others are beneficial, leading to desirable fermentations and changes; others again are indifferent, neither good nor bad, but harmless.

As the milk comes from the cow it is almost free from bacteria, but milk makes an excellent soil for many of these organisms to grow in, and they soon get in, to multiply with enormous rapidity at any temperature from 60° to 100° F.

=Lactic Acid Bacilli= are bacteria of special importance to the dairyman, for they convert sugar of milk into lactic acid and produce various more or less agreeable flavors. They are also powerful germicides and scavengers, destroying or neutralizing the products of other bacteria which in the absence of these bacteria and the lactic acid produced by them would play havoc with the food and produce putrefaction or disease. Everybody who handles milk knows that pure sour milk or buttermilk in which lactic acid bacteria abound keeps well for a long time, free from other fermentations which have no chance to develop in their presence. It is due to this purifying property that Metchnikoff recommended Bulgarian sour milk as a health food, asserting that it prevents harmful fermentations in the digestive channel.

The Control of Bacteria

The principal means at our disposal to prevent or control and regulate bacterial growth are:

Cleanliness, _Heat_, _Cold_ and _Disinfectants_.

=Cleanliness.=—Only the most scrupulous cleanliness will prevent contamination. Hence the necessity of thorough scouring and sterilizing of all utensils, and the need for fresh air and pure water.

=Heat.=—The prevention of fermentation in milk by heating is called “sterilization” or “pasteurization” according to the intensity of the heat and the length of time the milk is subjected to it. Boiling destroys almost all bacterial life. Some germs require, however, exposure to a much higher temperature, up to 250° F. (boiling under pressure), to be entirely eradicated, but for all practical purposes a thorough boiling is considered sufficient to eliminate all danger of contamination. Such boiling is usually termed _Sterilization_.

[Illustration:

Effect of heating milk to various temperatures. Published by the Toronto Board of Health]

=Cooling= checks bacterial growth and but few germs thrive at a temperature below 50° F. The following table and diagram[4] show how quickly bacteria multiply in milk at ordinary room temperature, 68° to 70°, which emphasizes the importance of keeping milk cool.

Relative growth of bacteria when held at different temperatures

■■■

supply should not only be cooled strongly, but must be kept thoroughly chilled up to the time they are used, which means that they should be delivered cool to the consumer, and kept on ice in the house, never being allowed to warm up until used.

[Illustration:

The diagram (after Conn) shows the rapidity with which bacteria multiply in milk not properly cooled. A single bacterium (a) in 24 hours multiplied to 5 (b) in milk kept at 50° F.; (c) represents the number that develop from a single bacterium in milk kept 24 hours at 70° F.]

=Disinfectants.=—Antiseptics, such as benzoate of soda, formalin, boracic acid, etc., are not permissible _in_ milk, but _disinfectants_ such as soda, lime, washing powders, etc., should be freely used in cleaning utensils, bottles, floors and walls where milk is handled, so as to prevent as far as possible any infection.

PASTEURIZATION

[Illustration:

Louis Pasteur, French scientist and originator of the process of pasteurization.]

Pasteurization depends upon the fact that almost all bacteria, and especially the disease-producing species, are checked in their growth and made harmless, if not totally destroyed, by instantaneous exposure to a temperature of 175° F., or a more or less prolonged exposure to lower temperature, for instance for 20 minutes to 157° or 30 minutes to 145°. These lower temperatures are recommended in the case of new milk to be consumed as such, in order not to change its digestibility. Pasteurizers with “holding devices” are therefore largely taking the place of the “continuous” sterilizing machines, which allow only momentary exposure to the highest temperature.

Whatever method is used it is essential that after the heating is finished the milk should be cooled as quickly as possible to a temperature sufficiently low to prevent development of the germs that have not been entirely destroyed by the heat and which, if the milk is left for any length of time at a temperature favorable for bacterial life—anywhere between 65° and 110°,—will begin to grow again. Cool the milk to below 60° and if possible to 50° or 40°.

Sometimes a second pasteurization is practiced, the milk being purposely allowed to stand at 70° to 80° for 12 to 24 hours after the first pasteurization for the germs which escaped destruction to develop into full-grown bacteria. They are then killed by the second heating before the milk is finally chilled to stop any further growth.

Pasteurization can be done by placing the milk in any tin or enamelled or glass vessel, set in another vessel containing water (a double boiler). Heat until the milk has reached the desired temperature, hold it at that temperature the necessary time, and then place the vessel in cold running water or in ice water until the milk is thoroughly chilled. It is not advisable to place the hot milk in the ice box as cooling in air is too slow. Not until it is thoroughly cooled in water is it safe to put it in the ice box to _keep_ it cool.

[Illustration:

N. J. Fjord, Danish investigator]

In the seventies Prof. N. J. Fjord, in Denmark, applied to milk the process which had been developed by Louis Pasteur in France to give keeping quality to wine and beer. A Danish dairy expert, J. Moldenhauer, now connected with the New York State Department of Agriculture, first brought the process to this country and used pasteurization in a city creamery in Kentucky. American experiment stations established the temperatures and the time of exposure necessary for best results, and no one has done more for the introduction of pasteurization than the New York philanthropist, Nathan Straus, who has established pasteurizing plants and milk distributing stations in many localities, thereby contributing so largely to the lowering of the death rate among the children of the poor.

[Illustration:

The Straus Pasteurizer]

[Illustration:

A continuous pasteurizer]

The following directions are given by the Straus Pasteurized Milk Laboratories of New York for the pasteurization of milk for babies:

1. Only use fresh, filtered milk, which has been kept cold, and proceed as follows:

2. Set the bottles, after they have been thoroughly cleaned, into the tray (a), fill them to the neck, and put on the corks or patent stoppers.

3. The pot (b) is then placed on a wooden surface (table or floor) and filled to the three supports (in the pot) with boiling water.

4. Place tray (a), with the filled bottles, into the pot (b), so that the bottom of the tray rests on the three supports, and put cover (c) on quickly.

[Illustration:

Milk cooler]

5. After the bottles have been warmed up by the steam for five minutes, remove the cover quickly, turn the tray so that it drops into the water. The cover is to be put on again immediately. This manipulation is to be made very quickly, so that as little steam as possible can escape. Thus it remains for twenty-five minutes.

6. Now take the tray out of the water and cool the bottles with cold water and ice as quickly as possible, and keep them at this low temperature till used.

7. Before use, warm the milk—in the bottles—to blood heat. Never pour it into another vessel.

8. The milk must not be used for children later than twenty-four hours after pasteurization. Never use remnants.

In a _Continuous Pasteurizer_ a constant stream of milk is fed into the machine, heated by flowing over a metal surface with steam or hot water on the opposite side, and cooled by running over a cooler furnished with a stream of cold water or ice water.

PURE CULTURES

[Illustration:

Professor V. Storch, originator of pure cultures for ripening cream and milk]

Before 1890 it was supposed that the flavor of fine butter depended upon certain volatile oils and acids peculiar to butter-fat. In the early nineties Professor V. Storch of the Danish Experiment Station showed, however, that it was due rather to the products of bacteria and he isolated the lactic acid bacilli which would produce such exquisite flavor even when perfectly neutral and tasteless butter-fat was churned with milk acidified or ripened with a pure culture of these bacilli. In this country Dr. H. W. Conn of Wesleyan University, Storrs, Conn., did much to advance the theory and practice of ripening cream with a pure culture starter.

“Pure cultures” are produced in the bacteriological laboratory by picking out under the microscope colonies of the desired species of bacteria, planting them in a sterilized medium and allowing them to grow under the most favorable conditions and with the exclusion of all other germs.

[Illustration:

Streptococcus lacticus (Storch, No. 18)]

[Illustration:

Bacterium lactis acidi (from Storch)]

When such a culture has reached its maximum growth it is transplanted into a larger quantity of a sterilized medium containing proper nourishment for the particular organism. In the bacteriological laboratory, where alone absolute sterility of utensils and medium, and entire exclusion of foreign infection are possible, the culture may remain pure while this inoculation and propagation are repeated over and over again. But when the propagation is carried on in the house or the dairy, for instance in preparing starters or buttermilk, such absolute cleanliness is impossible and in the long run infections will creep in from the air or from the utensils and after a while it becomes necessary to start with a new “pure culture.” How often such renewal must be resorted to

depends largely upon the surroundings and the care of the operator. Usually it must be done after a week's time, although it is surprising to find milk preparations made by the simplest processes equal in purity to those prepared with the assistance of bacteriological science and technique. This is, for instance, the case in Bulgaria, where the famous Yoghourt sour milk is prepared pure without special care and in Denmark where the country is fairly permeated with the lactic acid bacilli used in ripening the cream for the celebrated Danish butter and where careful buttermakers often maintain their starters for months or even for years without "renewal."

[Illustration:

Typical lactic acid bacteria (L. A. Rogers)]

There are many different varieties of bacteria which convert sugar of milk into lactic acid, at the same time developing flavors more or less agreeable and characteristic for the various products. In the bacteriological laboratory certain species are selected which will produce the results desired for the particular purpose in view.

=Starters.=—Beginning with a commercial dry culture in the form of a powder as generally used in the creamery or the cheese factory as well as for the preparation of commercial buttermilk, or with buttermilk tablets as used in the ordinary household or the hospital, such culture is added to a small quantity of thoroughly pasteurized milk. If fresh, sweet skim milk is available it is preferable to whole milk as the butter-fat in the latter only interferes with the process; but either can be used.

Milk for starters should be strongly pasteurized by being kept at a temperature near the boiling point—at least 180°—for 40 to 60 minutes, then cooled to the degree at which it is to be set, usually between 65° and 75°, somewhat higher for the first propagation with the pure culture than for the subsequent transplantings when the bacteria, more or less dormant in the dry powder or tablets, have attained full vitality. Some species of bacteria, as the Bacillus Bulgaricus, require higher temperatures—90° to 100° or even 110°—than others. The culture having been thoroughly incorporated in the milk by vigorous and repeated stirring or shaking, the milk is left at rest in an incubator or a waterbath or wrapped in paper or cloth in a warm room where an even temperature can be maintained, until it is curdled, which may take 18 to 24 hours or even longer for the first propagation.

One part of this curdled milk is now added to 5 or 10 parts of fresh pasteurized milk and set to ripen in the same way as described above, possibly at a little lower temperature, and this is repeated every day, thus maintaining the "Mother Starter." After the second or third propagation the bulk of each batch is used as a starter in the larger lot of material to be ripened, be it cream for butter or milk for cheese or for commercial buttermilk, while a little is taken for maintenance of the mother starter as described above.

The _amount of starter_ to prepare every day depends upon the amount of milk or cream to be ripened and the per cent of starter used in same. For instance, if you have ten gallons of cream to ripen every day in which you wish to use about 10% or 12% starter, or one gallon, take a little less than one pint of the first or second propagation for one gallon of milk; the next day use one pint of this to add to a gallon of fresh starter milk, and the remaining gallon to add to the ten gallons of cream, and so on every day.

If you have 4,000 lbs. of milk in the cheese vat to ripen with 2% or 80 lbs. starter, prepare 88 lbs. of mother starter. If, on the other hand, you wish to make only a quart of buttermilk every day, take, say, two buttermilk tablets, crush them thoroughly in a spoonful of pasteurized milk and stir this into a tumblerful of the same milk; let stand till it is thickened the next day and use a tablespoonful of this thickened milk in a quart of fresh pasteurized milk which when ripened is your buttermilk, from which you take out a tablespoonful for starter in the next batch, and so on. In this case there is no "mother starter" except that perhaps the first tumblerful prepared with the tablets may be called so, but afterwards the starter is taken right out of the finished product every day.

The process may be modified to suit special purposes and local conditions, but the following precautions should be strictly observed: (1) to interrupt the ripening immediately by quick and intense cooling as soon as it has reached the proper point in case the ripened product is not used at once, and (2) to _keep_ it ice-cold until it is used. If this is done, it may be kept for two or three days without deterioration if it is not convenient to make it fresh every day which, however, should be the rule.

CHAPTER II

MILK SUPPLY AND CREAMERY PRODUCTS

In the first chapter the composition of cow's milk and the nature of its constituents have been considered, the most important tests for its richness and purity have been described, and the ferments have been mentioned which instigate changes for good or for bad, together with the means at disposal for regulating their activity. To use these means intelligently in handling milk and its products is the key to the dairyman's success.

We shall now briefly consider the various steps that are of importance in modern dairy industry.

MILK SUPPLY

In the first place, the farmer must furnish pure, clean, unadulterated milk, fresh from the cow and cooled immediately after milking. His cows must be healthy.

=Bovine Tuberculosis.=—Many milk-cows, for the very reason that they have been bred with the one purpose in view of turning all their food into milk and wasting as little as possible in building up the body, are more or less weak-chested and apt to suffer from tuberculosis. Unless this disease is so far advanced as to affect the general health of the cow, or it has spread to the milk organs, the udder and the teats, it is not so dangerous as has heretofore been supposed. It is now held by the great majority of physicians that bovine tuberculosis is hardly ever transmitted to grown persons and seldom to children. Neither is it hereditary. Nevertheless, wherever it is possible to have the herd tested with tuberculin, segregating, if not killing, the animals which show by reaction that they are somewhat tuberculous, it should be done. Milk from such cows should always be pasteurized.

=Milk as a Disease Carrier.=—A greater danger lies in the fact that, warm as it comes from the cow, milk is an ideal medium for human disease germs to grow in, and may thus become a great conveyor of such germs. For this reason it is of the greatest importance that the milkers are healthy and clean, that the udders and teats be free from dirt, and the milk pail covered as far as possible; the barn must be clean, and every source of infection excluded. This fact also points to the advisability of pasteurization. On page 23 a chart is shown, published by the Toronto Board of Health and indicating the temperatures at which various germs of disease are made harmless.

=Bacterial Count.=—The test for clean milk now mostly used is the "Bacterial Count," the number of bacteria—or rather colonies of bacteria—found in a cubic centimeter of the milk. It would be better if the nature or quality of the bacteria could be taken into consideration as well as the quantity, but that being as yet impracticable, the next best thing is to depend upon the number. Ordinary good milk often contains hundreds of thousands of bacteria in a cubic centimeter, but where the greatest cleanliness is observed the number may be less than 1,000.

=Certified Milk= is now sold in many cities which, according to varying city ordinances, is guaranteed to have less than 10,000 or 20,000 or 30,000 bacteria, as the case may be.

[Illustration:

Counting the bacteria in a cubic centimeter of milk]

The cost of producing certified milk places it beyond the reach of the great majority of consumers. But such care and cleanliness as can be observed by the farmer and the milkman without extra expense should be insisted upon, and milk which nevertheless contains a large number of bacteria can be made safe by pasteurization.

=The Sanitary Code.=—The regulation of the production and delivery of milk in cities and towns as well as at creameries and cheese factories, the "Sanitary Code" established by state and municipal health authorities, has been very effective in improving the quality of the supply. So enormous have been the improvements in caring for and handling the products by the large establishments engaged in the delivery of milk as to make the increase in cost seem trifling compared with the great benefit to the public health secured by these agencies.

=New York State Milk Grading.=—The New York State Board of Health prescribes a grading for milk offered for sale, the most important features of which are as follows:

Certified.—Must be produced under specially sanitary conditions approved by a county medical commission.

Grade A Raw.—Cows must be tuberculin tested and milk must not contain over 60,000 bacteria per cubic centimeter.

Grade A Pasteurized.—Cows must be subjected to physical examination and milk must not contain more than 200,000 bacteria before, nor more than 30,000 after pasteurization.

Other grades permitted under the rules, all subject to inspection and approval of the authorities, are:

Grade B Raw. _Grade B Pasteurized._ _Grade C Raw._ _Grade C Pasteurized._

Deliveries must be made within a certain time after production or pasteurization, barns and milk stations are inspected, and altogether such safeguards are employed as to make the supply exceedingly safe and reliable.

=City Delivery.=—In villages and small cities the milk supply is still to a large extent in the hands of farmers who come to town early in the morning peddling their milk, often at considerable waste of time for horse and man. Or a number of peddlers go over the same route so that it takes a dozen wagons to cover a town where three or four could do it.

As long as there was no efficient regulation as to price and quality such waste was perhaps unavoidable, as competition on the part of the producers and distributors was the only means of protection for the consumers. But lately state and municipal control is being exercised to such an extent as to largely eliminate the danger of poor milk and exorbitant prices. Further development of organized delivery systems so much to be desired for sanitary as well as for economical reasons, may be looked for as soon as normal conditions return after the close of the war. The delivery of milk is one of the things that in the interest of public health must be under the strictest official control, and _co-operation_ between farmers and consumers is the logical system for elimination of unnecessary expenses of distribution and for prompt and satisfactory service. Their interests are or should be identical and both classes are hurt by inefficient and wasteful delivery.

In the large cities there has grown up an industry which largely monopolizes the milk supply and which until lately was powerful enough to dictate prices and conditions both for producers and consumers. Several attempts have been made from time to time by farmers to combine to regulate prices and dictate the terms to the middlemen. Such attempts have, however, invariably failed as long as they were built on false economic principles and prompted by selfish interests only. No farmers' association can be strong enough to ignore the law of supply and demand, and it is only quite recently that the _Dairymen's League_ has succeeded in influencing the market by taking into consideration the actual cost of production of milk as worked out by the agricultural colleges, and fixing the price on a scientific basis. There is one other element entering into the causes on which the price to the consumers depends, namely, _Transportation_, and while municipal boards of health are looking after the sanitary conditions and prevention of adulteration, State and Federal authorities are stepping in as moderators or arbitrators to reconcile the interests of the _Producers_, the _Railroad Companies_, the _Distributors_ and the _Consumers_. The next step in the development will no doubt be towards full co-operation between producers and consumers and, to a large extent, elimination of the "middlemen."

It should not be forgotten, however, that while the much abused middlemen in time past have been able to dictate terms and prices and have often abused the privilege; they have at the same time used their influence and power to improve the milk supply. As the supply of oil and gasoline has been perfected and cheapened by the all-powerful Standard Oil Co. as a monopoly crushing all competition, so the "Milk Trust" has improved the distribution of milk and has built up the magnificent sanitary plants in which milk is handled, pasteurized, bottled and distributed in a way that might not have been possible without the monopoly. It has served a good purpose, but has at the same time acquired such power that official control has become necessary for the protection of producers and consumers alike, and the time may be near when these two classes will combine and take the matter into their own hands so that the distribution may be done at actual cost.

[Illustration:

Milk station in the country where milk is received from the farmers to be shipped to the city]

=Milk Stations= are plants erected in dairy sections in the country either by the city milk supply houses or by co-operating farmers, where the milk is delivered and handled so as to make it ready for shipment to the city. As in the creamery and the cheese factory, the milk is carefully examined and, if it is not sweet and pure, it is rejected and sent back to the farm. Any impure flavor remains in the cover for some time and is easily detected by smelling of the cover as soon as it is removed from the can.

A sample is taken and put aside for the Babcock test and perhaps another for the Fermentation test. Each farmer's milk is weighed in the _Weigh Can_ and run through a cheese-cloth strainer. The further treatment varies in different plants. The milk may simply be cooled by running it over a cold water or brine cooler and placing it in shipping cans in the refrigerator or in ice water until the

milk-train comes along to pick up the cans. Or it may be clarified by running it through a centrifugal machine, the same as a separator, in which, however, cream and milk are not separated, but impurities are thrown out by the centrifugal force and deposited on the wall of the bowl, and the purified milk may then be pasteurized and bottled before being shipped to the city.

[Illustration:

Receiving milk at the milk station]

Arriving in the city in iced cars the milk is taken to one of the elaborate plants in which it is pasteurized and bottled, if that has not been done at the country station. The machinery used in these plants is getting more and more perfect and expensive and leaves little to be desired as to sanitary requirements and economy in handling. Pasteurizers, bottling machines, bottle-washing machines, conveyors, etc., are wonders of ingenuity, and one needs only to see one of these modern plants to understand that in a large city milk can only be handled to advantage in expensive establishments.

=Skim Milk= is one of the cheapest of foods and under proper regulations its sale should not be prohibited. The reason why in times past skim milk has been discredited and excluded from sale was that, as produced by the old methods of raising the cream, before the advent of the separator, it was always more or less old and sour before it was available and certainly before it could be distributed to consumers. Under such conditions it was hardly ever fit for human food. But when produced by the separator and pasteurized and cooled immediately after—within a few hours after milking, which is entirely feasible—it is an excellent and nutritious food for adults and even for children over two years of age. Ripened with a pure culture of lactic acid bacteria, it makes a healthful, refreshing drink, like buttermilk. Only when it is allowed to sour without proper care or control does skim milk, as whole milk does, become unfit for food or drink. On a cold winter morning when men are going to work (or perhaps are looking for work which they cannot find), and children are on their way to school, often underfed, a street-corner wagon or stand where boiling hot, fresh, sweet skim milk might be distributed at a cent or two a glass would be a blessing in any city.

[Illustration:

Pasteurizing and bottling milk in a Borden plant]

CREAM

When new milk is left at rest the cream will rise to the top and after 12 to 24 hours a cream-line can be seen in the bottle. This cream-line is sharper and more easily seen in raw milk than in pasteurized milk and its absence is not always a sure sign of lack of richness or purity of the milk. By cooling the milk thoroughly so that it will keep, almost all the cream will be at the top in forty-eight hours and can be skimmed off. The cream can be used for coffee or on cereals or fruits or puddings; the skim milk left will still hold ½% or more of butter-fat and can be used to drink or for cooking.

=The Separator.=—On the farm or in the creamery the cream is no longer raised by gravity, that is, by letting the milk “set” either in shallow pans on the kitchen shelf or in deep cans in ice water, but the fresh, warm milk is run through the separator in a continuous stream.

[Illustration:

Early conception of the separator]

It was noticed that the rising of the cream due to the difference in specific gravity between the butter-fat and the milk-“serum” (the watery solution of the other constituents) might be greatly hastened by subjecting the milk to centrifugal force. This physical phenomenon was taken advantage of in the first conception of the separator where it was shown that if a pail of milk was whirled around like a stone in a sling the heavier milk-serum would be thrown towards the bottom of the separator pail with so much greater force than the lighter cream (butter-fat mixed with a small part of the serum) that the separation which would take 48 hours in the milk at rest, could be accomplished in a few minutes when exposed to centrifugal force. From this early crude attempt the continuous _bowl-separator_ was developed and still later a number of divisions in the bowl were designed which increased the capacity and efficiency of the machine wonderfully. The most successful separator was designed by Dr. Gustaf De Laval of Sweden and the machines bearing his name are used all over the world where butter is made. But there are many other excellent separators on the market.

[Illustration:

Dr. Gustaf De Laval of Sweden, inventor of the separator bearing his name]

In the machine the milk is separated instantaneously by centrifugal force and runs out through two tubes, one for cream and the other for skim milk. A small modern hand machine will take care of from 200 to 1,000 lbs. of milk an hour, and power machines are built to separate 6,000 lbs. or more. By regulating the cream-outlet a heavier or lighter cream can be produced.

[Illustration:

Hand separator]

Suppose we are separating some milk containing 4% butter-fat. If ■ of this milk is separated out as cream and contains all the butter-fat, the cream will be eight times as rich in butter-fat as the original milk; 32% of the cream will be butter-fat. Such cream is called “32% cream.” If we take ¼ as cream, we get a cream four times as rich as the milk, a “16% cream.” So out of 100 lbs. of milk we can take 12½ lbs. (■) of 32% cream, 25 lbs. (¼) of 16% cream, etc.

Although the skim milk is really valuable as a food, it is worth but little commercially; the cream containing the butter-fat is the expensive part of the milk, and we must be prepared to pay for the cream all that the milk would have cost.

=Percentage of Butter-Fat.=—The “richness” of cream or milk and their value depend upon the amount of butter-fat in them. So cream or milk is often called “30% cream” or “20% cream” or “4% milk” according as 30% or 20% or 4% of the fluid is butter-fat; 30% cream is quite rich; ordinary market cream varies between 18% and 40%, though it may fall below 18%, or it may be sold as a very expensive article as high as 60%. Rich milk may contain more than 6% of butter-fat and skim milk less than 0.1 of one per cent. The average for good whole milk is between 3% and 4½%.

For a long time scientists and scientific dairymen were the only ones to speak of milk and cream in terms of percentage of butter-fat. Now, however, people are beginning to realize how valuable a part of the milk the butter-fat is and are paying more attention to the actual percentage of butter-fat in the cream or milk they use. So it is no longer unusual to see a dairyman advertise cream of a certain percentage or to hear a housewife ask for it specifically.

=Standardizing Cream.=—For ice cream or for preparing modified milk for babies, it is often desirable to dilute rich cream to a certain lower standard. The following simple steps can be taken to find out how much milk to add for diluting:

1. From the test—fat-percentage—of the rich cream subtract the test desired.

2. From the test desired subtract the test of the milk used for diluting.

3. Divide the first difference by the second, and the result will be the number of pints (or pounds) of milk to be added for each pint (or pound) of the rich cream.

For instance, you may want to thin some 30% cream to 10% for making ice cream. The milk to be added is skim milk. Then:

1. 30 - 10 = 20.

2. 10 - 0 = 10.

3. 20 divided by 10 = 2. So for each pint of rich cream you may add 2 pints of skim milk.

Or you may wish to thin the 30% cream with whole milk, which has 4% butter-fat. Again:

1. 30 - 10 = 20.

2. 10 - 4 = 6.

3. 20 divided by 6 = 3■. So you may add 3■ pints of the whole milk to each pint of the 30% cream and still have a 10% cream.

=Pasteurized Cream= does not look as rich as raw cream, and fresh, sweet cream appears to be thinner than when it is 24 hours old and slightly ripened. So it is well, when buying cream, not to judge by appearances. Demand of the milkman that he furnish you cream of a certain percentage of butter-fat and see to it that you get what you pay for. If you have no Babcock tester the milk inspector will test the cream for you.

=Whipped Cream.=—For whipping, cream must be fairly rich, from 24% to 32%, and it must be cold. Fresh, sweet cream does not whip as readily as that which has been kept for 12 or 24 hours in ice water. There is no other secret connected with the process. Use a rich cream, suitably cooled and aged, and with a good beater there can be no trouble in getting a fine, stiff whipped cream. If the cream is too thin or too warm it may not become stiff. Sometimes, when it is beaten too long, it turns into butter and buttermilk.

[Illustration:

Installation in a Danish creamery. From the separator at the right the cream runs through the continuous pasteurizer which forces it up over the cooler whence it runs into the cream-vat at the left. (From Boggild—Maelkeribruget i Danmark)]

=Emulsified Cream.=—One of the recent additions to the already elaborate machinery used in the creamery, the milk supply or the ice cream business, is the _Emulsifier._ To be sure, emulsifiers were used thirty to forty years ago to mix animal and vegetable fats—oleomargarine oil, lard and cottonseed oil—into skim milk for “Filled Cheese” or for Butterine, but lately they are serving new purposes in the milk industry. By forcing melted butter-fat or oil mixed with water or skim milk through exceedingly small apertures under high pressure, or otherwise breaking up the mixture, an emulsion can be formed in which the fat globules are much finer even than those in natural milk or cream, and separation can be prevented. The force used in these emulsifiers may be produced by powerful pumps, or a steam jet, or centrifugal force under high speed; whichever system is used the machines answer the same purpose, to produce a permanent emulsion in which the oil or fat will stay in suspension even after cooling. In some milk supply plants and ice cream factories all the cream is emulsified and the system has especially been applied since the advent of the milk powder. It is now a not infrequent practice to run the new milk through the separator, make sweet, unsalted butter from the cream, and milk powder from the skim milk, and to ship or store these products separately where or until cream is wanted and then bring them together again by running them through the emulsifier with a suitable amount of water. At first thought this process would seem impractical and uneconomical. But it has proven good business because in many cases and places skim milk powder and butter keep better separately or can be shipped at long distance to better advantage than new milk or cream or condensed milk. In ice cream factories business may be dull in cold weather and cream is perhaps not provided and not available, when suddenly a hot spell brings orders for large quantities. With a stock of skim milk powder and butter on hand in the refrigerator, and an emulsifier to mix these products, cream can be produced on short notice and there will be no danger of shortage.

ICE CREAM

Ice cream has fast become the national dessert served on all festive occasions, winter and summer. Originally it meant a frozen mixture of sweetened and flavored milk and cream, but the name has long been applied to all kinds of frozen delicacies in which cream enters as a constituent. Not even there has the line been drawn, but gums, gelatine, cornstarch, eggs and other “fillers” have been substituted or added to thicken the mixtures and give “body” to “creams,” which have but little relation to the genuine emulsion of butter-fat from cow’s milk. Standardization has been attempted by National and State food authorities with varying success of enforcement. While the application of the name to a great variety of frozen desserts has no doubt become legitimate by long usage it may properly be demanded that as an article of merchandise “ice cream” shall contain at least 8% to 12% butter-fat and that no ingredients dangerous to health enter into its manufacture.

[Illustration:

Hand freezer]

=Freezers.=—The freezing is usually done by contact of the material with metal cooled on the other side by a “freezing mixture” of salt and ice which produces temperatures far below the freezing point of water while air is whipped into the cream by the rapid motion of the beater. A great variety of excellent freezers of this kind for hand or for power are on the market which answer the purpose for making ice cream at home or at the ice cream parlor.

Coarse-grained salt and crushed ice, mixed in the proportion of 1 part salt to 4 parts of ice, are constantly filled into the space surrounding the ice cream can, and the brine produced by the melting of the mixture is gradually drawn off from the tub. In a good freezer the operation should not take over fifteen minutes. When the cream is frozen to a soft mush, stop the beater and scrape down the hard particles which may have accumulated on the sides of the can, add any ingredients which may be better incorporated at this stage than mixed into the original material, such as crushed fruit or preserves, and finish the freezing without carrying it too far.

Remove the beater, stir the cream which should still be soft enough to handle, and pack in ice with only a little salt. Or the cream may be transferred from the freezer can to the shipping can and packed in it. If bricks are wanted the soft cream is packed in molds of the desired shape and size and buried in the freezing mixture to harden.

In modern ice cream factories _Brine Freezers_ are generally used. In a _Refrigerator Plant_ intensely low temperatures are produced by the vaporizing of compressed ammonia or carbonic acid in an ice machine, and brine circulating in iron pipes is cooled by such medium and may, in turn, cool the air in the _Cold Storage_ room, or the cream in the freezer, or pure water in metal boxes for the manufacture of _Artificial Ice._ It has been attempted to make the brine freezers _continuous_, the cream mixture being fed into the machine at one end and discharged frozen at the other. But this system has not so far been successful, and intermittent or batch freezers are most practical yet both for hand and for power.

[Illustration:

Power brine freezer]

Rich material, frozen in a good machine, whether intermittent or continuous, will expand from 50% to 100%, and the original material should not fill the freezer can more than half full.

The manufacture of ice cream has been the subject of study and experiments for years in the Dairy Department of the Agricultural College at Ames, Iowa, where Professor M. Mortensen has worked out a comprehensive classification from which any manufacturer may readily choose his formulas, modifying them to suit his local conditions and special problems. The outline kindly furnished the author by Professor Mortensen is so interesting and instructive as to be well worth copying substantially in full, leaving out the “Ices” in which no milk or cream is used and which are therefore not of special interest in connection with the purpose of this book—the use of more and better milk.

[Illustration:

Ice cream factory]

CLASSIFICATION ADOPTED AT IOWA EXPERIMENT STATION

Considering the work of former writers as well as names used by business men, the following classification was worked out by the station:

I. Plain Ice Creams. II. Nut Ice Creams. III. Fruit Ice Creams. IV. Bisque Ice Creams. V. Parfaits. VI. Mousses. VII. Puddings. VIII. Aufaits. IX. Lactos.

Explanation and Formulas

I. _Plain Ice Cream_ is a frozen product made from cream and sugar with or without a natural flavoring.

Formulas are given for making ten gallons of finished ice cream.

Vanilla Ice Cream:

5 gallons 25% cream 8 lbs. sugar 4 oz. vanilla extract

Chocolate Ice Cream:

5 gallons cream 10 lbs. sugar 1½ lbs. bitter chocolate 4 oz. vanilla extract

Maple Ice Cream:

5 gallons 25% cream 6 lbs. cane sugar 2 lbs. maple sugar 2 oz. caramel 4 oz. vanilla extract

Caramel Ice Cream:

5 gallons 25% cream 8 lbs. sugar 12 oz. caramel 4 oz. vanilla extract

Coffee Ice Cream:

5 gallons 25% cream 8 lbs. cane sugar Extract from 1 lb. coffee

Mint Ice Cream:

5 gallons 25% cream 8 lbs. cane sugar 1 pt. concentrated Creme de Menthe syrup Few drops green coloring.

II. _Nut Ice Cream_ is a frozen product made from cream and sugar and sound non-rancid nuts.

Walnut Ice Cream:

5 gallons 25% cream 8 lbs. cane sugar 4 oz. vanilla extract 4 lbs. of walnut meats.

According to this general formula the following nut ice creams may be prepared by substituting different kinds of nut meats:

Chestnut Ice Cream _Filbert Ice Cream_ _Hazelnut Ice Cream_ _Pecan Ice Cream_ _Peanut Ice Cream_ _Almond Ice Cream_ _Pistachio Ice Cream_.

At times pistachio ice cream is made from oil of pistachio instead of from the nuts. If thus prepared, it will come under the head of plain ice cream.

III. _Fruit Ice Cream_ is a frozen product made from cream, sugar and sound, clean, mature fruits.

Strawberry Ice Cream:

5 gallons 25% cream 8 lbs. sugar ½ gallon crushed strawberries.

Employing the same formula the following creams may be made by merely substituting other fruits and berries for the strawberries. The amount of sugar may be varied according to the acidity of the fruit.

Pineapple Ice Cream _Raspberry Ice Cream_ _Cherry Ice Cream_ _Peach Ice Cream_ _Apricot Ice Cream_ _Currant Ice Cream_ _Grape Ice Cream_ _Cranberry Ice Cream_.

Preparation of _lemon_ and _orange_ ice creams cannot be included under this general rule. These creams may be prepared as follows:

Lemon Ice Cream:

5 gallons 25% cream 10 lbs. sugar 2 pts. lemon juice 1 pt. orange juice

Orange Ice Cream:

5 gallons 25% cream 10 lbs. sugar 2 qts. orange juice ½ pt. lemon juice.

IV. _Bisque Ice Cream_ is a frozen product made from cream, sugar and bread products, marshmallows or other confections, with or without other natural flavoring.

Macaroon Ice Cream:

5 gallons 25% cream 8 lbs. sugar 4 oz. vanilla extract 5 lbs. ground macaroons.

From this formula we can make:

Grape Nut Ice Cream Nabisco Ice Cream Sponge Cake Ice Cream Marshmallow Ice Cream.

V. _Parfait_ is a frozen product made from cream, sugar and egg yolks with or without nuts or fruits and other natural flavoring.

Walnut Parfait:

4 gallons 30% cream Yolks of 10 dozen eggs 14 lbs. sugar 4 oz. vanilla extract 4 lbs. walnut meats.

From this formula by substituting the nut meats we can make:

Filbert Parfait _Almond Parfait_ _Peanut Parfait_ _Hazelnut Parfait_, etc.

By substituting the same proportion of fruits as are used for fruit ice cream, for the vanilla extract and nut meats, fruit parfaits such as strawberry, raspberry and cherry parfaits and others may be prepared.

Coffee Parfait:

4 gallons 30% cream Yolks of 10 dozen eggs 14 lbs. sugar Extract from 1 lb. coffee

Maple Parfait:

4 gallons 30% cream Yolks of 10 dozen eggs 4 lbs. maple sugar 10 lbs. cane sugar 2 oz. caramel paste

Tutti-Frutti:

4 gallons 30% cream Yolks of 10 dozen eggs 14 lbs. cane sugar 4 oz. vanilla extract 3 lbs. candied cherries 3 lbs. candied assorted fruit 3 lbs. pineapple.

VI. _Mousse_ is a frozen whipped cream to which sugar and natural flavoring have been added.

Cranberry Mousse:

2 gallons 30% cream 4 lbs. cane sugar 1 qt. cranberry juice ¼ pt. lemon juice.

From the same formula combinations may be made with various other fruit juices and natural flavors, such as coffee, vanilla, maple, caramel, pistachio, etc.

Sultana roll, as indicated by the name, is made in a round mold. The center of the mold is filled with tutti-frutti, and the outside with pistachio mousse.

VII. _Pudding_ is a product made from cream or milk, with sugar, eggs, nuts and fruits, highly flavored.

Nesselrode Pudding:

3 gallons 30% cream 10 dozen eggs 10 lbs. cane sugar 4 oz. vanilla extract 6 lbs. candied cherries and assorted fruits 4 lbs. raisins 4 lbs. macaroons

Manhattan Pudding:

3 gallons 30% cream 10 dozen eggs 12 lbs. sugar 2 qts. orange juice 1 pt. lemon juice 4 lbs. walnut meats 4 lbs. pecan meats 4 lbs. cherries and assorted fruits

Plum Pudding:

3 gallons 30% cream 10 dozen eggs 10 lbs. sugar 2½ lbs. chocolate 4 lbs. cherries and assorted fruits 2 lbs. raisins 2 lbs. figs 1 lb. walnut meats 3 teaspoonfuls ground cinnamon ½ teaspoonful ground cloves.

VIII. _Aufait_ is a brick cream consisting of layers of one or more kinds of cream with solid layers of frozen fruits.

Fig aufait may be made from three layers of cream of various flavors with two layers of whole or sliced figs. It is most satisfactory to slice the figs lengthwise in halves.

Other aufaits may be made from a variety of preserved fruits and berries and combined with different creams.

IX. _Lacto_ is a product manufactured from skimmed or whole sour milk, eggs and sugar, with or without natural flavoring.

Formulas for lactos may be found in Bulletin No. 140 published by the Ames Station.

As an example, the following mixture will make 5 gallons of

Cherry Lacto:

3 gallons lacto milk 9 pounds sugar 12 eggs 1 quart of cherry juice or concentrated cherry syrup 1½ pints lemon juice

“Lacto Milk” is the same as described under “Commercial Buttermilk” and “Thick Milk,” pages 81 and 82.

The sugar is first dissolved in the lacto milk. The eggs are then prepared. The whites and yolks are kept in separate containers and each lot is beaten with an egg beater. Both the yolks and whites are then added to the milk. The mixture is thoroughly stirred and strained through a fine wire gauze. The fruit juices are added last. The freezer is now run until it turns with difficulty when the paddle is removed. The brine is removed and the freezer repacked with ice and salt and left for an hour before the contents are served.

Orange, Mint, Pineapple, Maraschino, Raspberry or Grape Lacto may be prepared by substituting any of these flavors for the Cherry.

X. _Ices_ are frozen products made from water or sweet skimmed or whole milk, and sugar, with or without eggs, fruit juices or other natural flavoring.

Ices may be for convenience divided into _sherbets_, _milk sherbets_, _frappes_, _punches_ and _souffles_.

Milk Sherbet is an ice made from sweet skimmed or whole milk with egg albumen, sugar and natural flavoring, frozen to the consistency of ice cream.

Pineapple Milk Sherbet:

6 gallons milk 20 lbs. sugar Whites of 2 dozen eggs 1 gallon pineapple pulp 1 qt. lemon juice.

Milk sherbets of various flavors may be prepared according to above formula by substituting other flavorings.

The formulas presented above have been given mainly for the purpose of making clear the difference between the various groups. Numerous other formulas may be prepared on the same general outline.

* * * * *

Prof. Mortensen's formulas are mostly made out for ten gallons of ice cream. It is hardly necessary to call attention to the fact that they can easily be adapted to any smaller quantities by reducing each of the ingredients alike. For instance, to make:

1 gallon of Plain Vanilla Ice Cream, divide the figures given above by 10 and use:

2 quarts 25% cream ¾ lbs. sugar ½ oz. vanilla extract.

To make:

1 quart of Strawberry Ice Cream, divide by 40 and use:

1 pint 25% cream 3 oz. sugar Crushed strawberries to taste.

[Illustration:

Professor Mortensen, behind the vat at the left, giving a lesson in the making of ice cream at Ames]

It will be noticed that in the formulas worked out at Ames as above, very rich cream is used,—with a fat contents of 25% or 30%,—which makes exceedingly rich ice creams and great expansion in freezing. The ordinary ice cream maker will usually employ cheaper material, mixing some milk in the cream and standardizing the material to suit his local trade. Also most housekeepers making ice cream at home will find it convenient and economical to use a mixture of milk and cream and in doing so one must not expect so much expansion.

In many places outside of dairy sections cream is scarce and _condensed milk_ is substituted to a large extent. Lately milk powder has come into use and _Emulsified Cream_ has become popular. Skim-milk powder and unsalted butter may be kept in stock and be available at any time, and by means of an _Emulsifier_ they are united again into a product identical with the milk or cream from which they were originally separated.

=Junket Ice Cream.=—By setting a mixture of milk and cream with a solution of Junket Tablets and allowing it to jelly before freezing, the body of the cream may be improved so that a material of comparatively low fat-percentage will make a very good ice cream, rich enough for most people and especially well suited for invalids and children. Ice-cold milk or cream is rather hard to digest for a weak or delicate stomach because the action of the rennet in the digestive juice is imperfect and slow except at blood-temperature. In Junket Ice Cream, however, such action takes place before it is eaten and the digestive ferment of the

stomach is relieved of that function. For that reason Junket Ice Cream is considered healthier than the ordinary frozen products and may be indulged in freely by children and invalids.

The following are examples of tested Junket Ice Creams:

Vanilla Ice Cream

Dissolve two Junket Tablets in a tablespoonful of cold water, heat two quarts of milk and one pint of cream lukewarm in which has been dissolved one cup of sugar and two teaspoonfuls of vanilla flavor, then add the dissolved Junket Tablet, stir quickly for one-half minute and pour into ice cream can, let stand undisturbed ten or fifteen minutes or until set. Pack with ice and salt and freeze.

Pistachio Ice Cream

Excerpt from an article by Alice Bradley in “Woman’s Home Companion”

This is the best ice cream for the money that we know. It may be made ready for the freezer early in the morning, and kept in the ice box until it is convenient to freeze it. It is quite possible to utilize cream that is not perfectly fresh.

Put in the can of the freezer one pint of milk, one-half cup of heavy cream, one-third cup sugar, one teaspoonful vanilla, one-half teaspoon of almond extract, a few grains of salt, and vegetable color paste to make a delicate green color. Set the freezer in a pan of hot water. As soon as the mixture is lukewarm, add one Junket Tablet dissolved in one tablespoon cold water. Mix thoroughly and let stand until firm. Put in the ice box until ready to freeze, then put can in the freezer tub, adjust the crank, put in three small measures of ice that has been crushed in a heavy bag or shaved fine with an ice shaver, cover this evenly with one measure of rock salt, add three measures more of ice and one of salt, let stand five minutes and then turn the crank of the freezer for about ten minutes, when it may be turned a little more rapidly. Continue the turning until the mixture is firm.

Remove the dasher, pack ice cream solidly into the can, surround with four measures of ice to one of salt, cover with heavy burlap bag or newspaper and keep in a cold place until needed. Be sure the opening in the side of the freezer tub is not plugged up, so that any surplus of salt water will drain off instead of getting into the freezer. It may be necessary to repack the freezer if the cream is frozen very long in advance of the meal. The cream may be put into a mold, set in the fireless cooker kettle, surrounded with ice and salt and left in the fireless cooker all day. Peel peaches, cut in thin slices, sprinkle with sugar and set in the ice box to chill. To serve, place peaches in chilled dessert glasses, cover with ice cream and garnish each with a candied cherry.

In the following recipes the cream is added after the junket prepared from mixtures of milk, sugar and flavors has been partly frozen, a method which is preferred by many.

Coffee Ice Cream

Make a cup of very strong coffee, add it to two quarts of warm milk in which one cup of sugar has been dissolved, taste in order to see if the flavor is strong enough, add three dissolved Junket Tablets, stir quickly for one-half minute, pour into ice cream can and let stand undisturbed ten or fifteen minutes or until set. Pack with ice and salt; freeze to a thick mush before adding one pint of cream, then continue freezing.

Simmons College Peach Ice Cream

Heat two quarts of milk lukewarm in which has been dissolved one cup of sugar and two teaspoonfuls of vanilla flavor, add two dissolved Junket Tablets, stir quickly for one-half minute and pour into ice cream can, let stand undisturbed ten or fifteen minutes or until set. Pack with ice and salt; freeze to a thick mush before adding one pint of cream and crushed and sweetened peaches, then continue freezing. Save the needed amount of peaches to serve on top of ice cream.

Frozen pudding, strawberries, bananas, or pineapple, may be added in this way when making any Junket Ice Cream.

Orange Sherbet

Heat two quarts of milk lukewarm in which has been dissolved two cups of sugar, then add two dissolved Junket Tablets, stir quickly for a minute and pour into freezer can, let it stand ten or fifteen minutes before packing with ice and salt; freeze to a thick mush, then add juice and grated rind of six oranges and continue to freeze.

=Raspberry Sherbet= may be made in the same way by substituting for the juice and rind of oranges one quart of crushed and sweetened raspberries, and

=Pineapple Sherbet= by substituting two cups of grated and sweetened pineapple.

Custard Ice Cream

When cream is scarce many housekeepers substitute a mixture of eggs and milk. The following is a good standard recipe which can be varied by using different fruits and flavors the same as in any of the above combinations.

1 quart milk 4 eggs 2 teaspoons vanilla (more if desired) 2½ cups sugar 1 quart cream (or rich milk)

Scald milk, add sugar, then add the well-beaten eggs. Cook until thick, remove from fire and cool. Be careful not to cook too long or it will curdle. Then add the cream and vanilla and freeze.

BUTTER

As everybody knows, butter is one of the oldest and most important products of the dairy industry and since the middle of the nineteenth century, when science was first applied to it, the art of buttermaking has gradually been developed to a high degree of perfection, while the taste for fine butter has grown apace with its manufacture.

Between 1840 and 1850 the large estates in Holstein, then connected with Denmark, were known for their fine dairies and excellent butter, made in a practical way without much attention to the reason for the rules that were gradually worked out.

A class of superior dairymaids was educated on these large farms, many of whom were hired by progressive farmers on the Danish islands where an effort was made at that time to introduce better methods of dairying.

The practical handicraft of these imported expert dairymaids was supplemented and regulated by the scientific work of Professor Segelcke and his pupils and from the Sixties buttermaking became an art in Denmark which was subjected to the most searching study and improvements. Danish butter soon captured the English market where previously Isigny (from Northern France) and Dutch butter had commanded the highest prices, and Danish sweet butter put up in sealed tin cans also became known all over the world as the only butter that would stand export to the Tropics.

In this country Orange County, N.Y., first produced a high-class article and, later, Elgin, Ill., became the center that stood for the top of perfection. Thence the industry soon spread over the middle western states, largely populated by Scandinavian immigrants many of whom were skilled buttermakers, educated in the old countries. Even up to this day it is noticeable that the list of prize winning buttermakers at the National Dairy Shows and other exhibitions is largely made up of Scandinavian names. In Minnesota, for instance, as fine butter is now made as anywhere in the world.

Dairy Butter.—In the early days of the industry butter was made at home on the farm. The milk was set in shallow vessels,—in the Holstein and Danish dairies in wooden tubs 24 inches in diameter placed on the stone or concrete floor in the milk-vault, a cool cellar partly underground,—or in tin pans on the pantry shelf. After 36 to 48 hours the cream was skimmed off with a flat scoop, often both cream and skim milk being sour.

About 1860 the deep tin can was introduced, set in cold running water or, where ice was available, in ice water. This was a great improvement over the shallow setting system. It was now possible to raise most of the cream in 24 hours leaving not to exceed ½% butter-fat in the skim milk, and to have both cream and skim milk sweet.

Centrifugal Creaming.—But the climax of perfection was not reached until the separator (see under Cream) was invented about 1879 and cream was raised instantaneously. For a long time it was the object of the manufacturers to produce _power separators_ of larger and larger capacity, handling from 6,000 to 10,000 lbs. of milk an hour.

=Co-operative Creameries= were established, taking in 20,000 lbs. of milk and more a day. But in thinly settled sections where the roads were poor it was expensive to haul the milk a long distance to the creamery and _hand separators_ were introduced, each farmer skimming his own milk fresh from the cows and delivering the cream, only, to the creamery. This system has the advantage of leaving the skim milk on the farm in the very best condition for the calves and hogs and of saving time and expenses in transportation. It has the disadvantage that many farmers can hardly be expected to handle all of these separators as skilfully and cleanly as the creamery expert can run his one or few machines, and consequently that the skimming is more or less

imperfect—more butter-fat being left in the skim milk and more impurities in the cream than in the whole-milk creamery. But in practice the advantages of the hand separator and cream-gathering system seem to be greater than the disadvantages and it is rapidly taking the place of the whole-milk creameries.

Ripening the Cream.—Butter may be made by churning whole milk, but usually it is made from cream that has been “ripened” or soured by standing for about 10 hours at a temperature of from 65° to 75° F. Modern buttermakers often pasteurize the cream and then add a “starter” to sour it. By preparing the starter with a pure culture of lactic acid bacteria one can get the desired acidity and aroma, and exclude undesirable flavors (as to Pure Cultures and Starters, see under “Bacteria” and “Commercial Buttermilk”).

[Illustration:

Sanitary Cream Ripener showing coil swung up into cleaning position]

The process of ripening requires considerable skill and attention and is one of the most delicate functions the buttermaker is called upon to perform. In the first place the cream must be faultless, sweet and pure before it is set to ripen, so the buttermaker will have full control of the fermentation. For, if it is already turned or partly fermented, no skill will avail to bring it back to perfection. But with a first class, pure cream the operator has it in his power to turn out perfect butter. In the big western creameries cream is often collected from farms at a distance of a hundred miles or more and in warm weather such cream is likely to arrive at the central plant in more or less advanced condition. It is therefore difficult for the _centralizers_ to make really first-class butter while the “whole-milk creamery” as well as the farmer handling his own milk are in position to control the ripening from the beginning,—starting with pure material and being able to develop the desired flavor and acidity in the cream.

After adding the starter to the cream it must be kept at a uniform temperature of 65 to 75° during the ripening process and it must be watched carefully and occasionally stirred gently until the consistency, aroma and acidity are as desired. Then it should be cooled quickly to stop further fermentation and if it is not to be churned at once it should be kept cold until churning time. Usually it is safer to set the cream in the morning and hasten the ripening so it will be completed in the evening rather than to leave it overnight warm. For, if it is finished in the evening, the cream may be cooled and placed in ice water overnight and one is sure to have it in good condition for churning in the morning. But it is quite feasible for the experienced operator to regulate the process so the cream will not be fully ripened in the morning until he is on hand to watch it and see that the process does not go too far. Taste and smell will tell when it is just right, and the _acid test_ may also be applied to determine when to stop the fermentation. An acidity of .5% is usually desired. When the condition is right, chill the cream, cooling it to below 50°—preferably down towards 40°—and leave it in ice water or in the refrigerator until churning time; then temper it to the proper temperature for churning.

Even if it is to be churned soon after the ripening is completed it is best to chill it and then raise the temperature to the point wanted for churning. This gives a better “grain” and “body” to the butter than if the ripened cream is just cooled to the churning temperature, and is especially desirable when the cream has been pasteurized.

[Illustration:

Branch of the Annatto tree]

=Coloring.=—When the cream is ready it is poured into the churn and a little butter color is added. Some people prefer butter very light or even uncolored, but usually 1 to 2 teaspoonfuls of a standard butter color[5] to 10 gallons of cream will be found right, varying according to the season and the breed of cows furnishing the milk. The butter-fat in Guernsey and Jersey milk is naturally highly colored, while that in Holstein milk is comparatively white. When the cows are on fresh pasture in the early summer the butter-fat is more highly colored than when they are on dry food. The amount of coloring to be added to the cream is regulated to overcome such variations and make the butter of uniform color all the year round.

[Illustration:

Adding the butter color]

=Churning.=—Hundreds of varieties of churns have been constructed from time to time; 2,000 years ago Pliny described the old dash churn much the same as still occasionally used on the farm, and the principle involved in the process has not been changed. The object is to make the fat globules conglomerate into grains that can be collected and leave as little butter-fat as possible in the buttermilk.

[Illustration:

Old Arabian churn made out of the skin of a goat]

[Illustration:

Ancient churn]

[Illustration:

Danish churn]

The best temperature for churning varies from 48° to 56° and must be determined by local conditions and experience. To allow plenty of room for the cream to shake about, the churn should not be much more than half full. When the globules of fat suspended in the milk stick together and form granules as large as good sized pin-heads it is time to stop the churn and drain off the buttermilk. If the butter fails to “come” in half an hour or forty minutes it may be because the cream in the churn is too warm or too cold. A little cold or warm water, as the case may be, can be added as a simple remedy.

[Illustration:

Churning room in a large modern creamery]

Toward the end of the process care must be taken that the churn is stopped at the right moment, when the butter will separate clear from the buttermilk. After the buttermilk is drawn off pure cold water is poured into the churn and the butter granules are rinsed in it. This water again is drawn off and fresh cold water put in.

[Illustration:

Butter worker]

=Working the Butter.=—The butter can now be taken out with a sieve and worked on the butter-worker, or it may be worked in the churn. “Working” the butter consists in squeezing out the buttermilk and kneading the butter into a smooth but not “greasy” mass. If it is too warm and if it is worked too much, with a sliding motion instead of just pressing, the butter is apt to become greasy. If there seems to be any danger of greasiness, it is better to stop and put the butter in a cool place for a few hours to recover its elasticity. The working can then be finished safely.

=Salting.=—During this working process salt is added and thoroughly distributed and worked in. About half an ounce of salt is used for a pound of butter.

=Composition of Butter.=—When finished, the butter ought not to contain more than 12% to 15% of water, and there should be at least 80% of butter-fat. If all the butter-fat originally in the milk could be taken out in the butter, 100 lbs. of 4% milk should yield 4.88% (4.88 lbs.) of butter with 82% butter-fat. But a little is lost in the skim milk and more in the buttermilk, which usually contains ½% fat, so that about 4½ lbs. is all the butter that can be expected from 100 lbs. of milk.

=Overrun.=—Creamery men are much interested in the “Overrun” which means the increase from the churn over the amount of fat in the milk. For instance, if a quantity of milk containing 100 lbs. butter-fat as shown by the Babcock Test produces 114 lbs. of finished butter, the overrun is 14%. The buttermaker who gets the largest overrun by reducing the loss of butter-fat in the skim milk and the buttermilk to a minimum, keeping the percentage of water in the butter just below 16%, and yet producing high scoring butter, is considered most efficient.

=Packing.=—For the market, butter is packed in tubs or stone jars. Or it is molded in neat one-pound bricks and wrapped in parchment paper.

=Sweet Butter.=—Real “sweet” butter is churned from fresh, sweet, unsoured cream. But usually the name is given to the _unsalted_ and _uncolored_ butter that many people relish. Without the salt it does not keep as well as ordinary butter, and must be eaten quite fresh. Well-made salted butter will keep for months with ordinary care, and in cold storage it may be kept a year. But when it comes out of cold storage it must be used within a few weeks, for butter, like other cold storage foods, will soon spoil and become rancid when it is exposed to a higher temperature for any length of time.

=Renovated Butter.=—Butter that has become old and rancid can be “renovated.” The butter is melted and the butter-oil washed,—aërated in the renovating plants,—and then churned with fine-flavored sour skim milk. From the sour skim milk it gets back its old butter flavor. The granular physical consistency of fresh butter is gained by pouring the emulsified mixture over cracked ice or into ice water. By the time the excess of “buttermilk” has been removed by working, and salt has been mixed in, the renovated butter may be almost as good as fresh creamery butter.

=Oleomargarine= or =Butterine= is made in much the same way. A mixture of beef-fat (the soft part of beef-tallow) and lard and cottonseed oil is churned with sour milk and worked and granulated like renovated butter. For the better grades, some of the finest creamery butter is mixed with it, so that the mixture can hardly be distinguished from real butter.

=Coco-butter=, =Nut-butter=, etc., in great variety, are now also on the market as substitutes for butter, all prepared in a similar way, but lacking the vital unknown element that makes genuine butter so superior to substitutes.

BUTTERMILK

If the cream has been carefully ripened, with or without a pure culture starter, and it has shown the proper sourness when churned, the buttermilk will be of a pleasing taste and flavor. Its thickness will of course depend upon the amount of water, if any, added to the cream in the churn during the buttermaking. If the buttermilk is to be used for human food care must be taken not to dilute it too much.

=Cooling Essential.=—If buttermilk is left to stand for hours in a warm room, fermentation goes on and may soon spoil the buttermilk by making it sloppy or bitter. It should therefore be cooled at once when drawn from the churn; if kept in ice water it may remain in fine flavor for several days. Well taken care of it is not only a pleasing and refreshing drink but eminently healthful. In cooking, too, it can be used to advantage.

=Commercial Buttermilk= or =Cultured Milk= is simply carefully soured milk. It can be made at home from fresh milk either whole or skimmed or partly skimmed. Partially skimmed milk containing from 1% to 2% butter-fat is plenty rich enough and even better for most purposes than whole milk. The essential qualities of good buttermilk depend upon the proper ripening of the cream or milk, the development of a pure “breed” of healthful bacteria in a clean field free from weeds. Such a plantation or “culture” may be grown in milk as well as in cream. Its function is to turn the sugar of milk into lactic acid under the development of pleasing flavors and whether the butter-fat is removed by the separator or by churning makes little difference. In natural buttermilk there is always a little butter-fat—at least ½%—left, mostly in the form of fine granules, too small to be retained in the butter. If the same amount of butter-fat is left in skim milk and that is ripened and churned, the product will be identically the same as natural buttermilk from ripened cream.

=Ripening.=—For best result the milk should be pasteurized, not necessarily as thoroughly as for starters, but sufficiently so as to destroy all obnoxious bacteria and give those introduced through a pure culture starter a chance to grow. Buttermilk may, however, also be made from good, clean, unpasteurized milk of good flavor. Whether pasteurized or not the milk is set to ripen with from 5 to 10% starter at a temperature of from 65 to 75°. The preparation of starters is described under “Bacteria” and the ripening of the milk for “buttermilk” is essentially the same process (see also under _Ripening_ of cream for butter). When ripened to the desired acidity,—say .5% to .6% by the acid test,—stop further fermentation by thorough cooling.

=Breaking up the Curd.=—After cooling, the ripened milk may be broken up fine and if vigorously shaken or “churned” it will remain smooth and creamy. Otherwise it may separate into curd and whey. If churned long enough for the butter to form, it becomes absolutely identical with real buttermilk. But, for all practical purposes, a vigorous shaking for a few minutes is enough.

=Thick Milk.=—“Thick Milk” as eaten in Scandinavia is made in the same way as commercial buttermilk, except that the milk—rich whole milk—is set to ripen in the bowl in which it is to be served. Instead of being churned or stirred, it is left thick, to be served as a pudding, like Junket made from sweet milk. The rich layer of cream that forms on top is excellent. “Thick Milk” is eaten plain with the oatmeal for breakfast, or as a dessert with grated stale bread and sugar spread over it.

The uses of buttermilk in making pancakes and for many other culinary purposes are mentioned in the chapter on “Milk Cookery.”

[Illustration:

Dr. Elie Metchnikoff, author of “The Prolongation of Life”]

=Yoghourt= or =Bulgarian Sour Milk= is prepared with a culture of bacteria originally found in Bulgaria where Metchnikoff, the late director of the Pasteur Institute of Paris, found people living to exceptional old age which he ascribed to the fact that their principal diet is sour milk of very high acidity.

The theory is that a luxurious growth of lactic acid bacilli, acting as a germicide, destroys other fermentations in the lower intestines. The bacilli active in Yoghourt require a somewhat higher temperature for their best growth than the lactic acid bacilli predominant in sour cream for the finest butter, a fact which must be taken into consideration in preparing the various products.

FERMENTED MILK

In the preparation of Koumis, Kefir and other fermented milks of the same class, Yeast plays an important part, changing some of the milk-sugar into the alcohol which is found in these preparations in quantities up to 2%.

[Illustration:

Baba Vasilka, 126 years old and her son, Tudor, 101; Bulgarian peasants whose principal food has been sour milk all their lives]

=Koumis= was first made from mare's milk by the Tartars, but is now prepared in this country from cow's milk by the addition of sugar and yeast. As carbonic acid is developed in the process it is quite effervescent and may be regarded both as a food and a stimulant. It is sometimes prescribed by physicians in cases when the patient cannot retain other food.

=Kefir= is a similar preparation originally made in the Caucasus by a fermentation started by Kefir grains which contain both yeast and various bacteria. The dry Kefir grains are soaked, first in lukewarm water, later in lukewarm milk, for several days, until they develop so much gas as to float on the top. A couple of tablespoonfuls of the grains are then added to a quart of milk which is left to ferment at 70° F. under frequent stirring or shaking. When the fermentation is fully developed the grains are strained off and the milk is bottled and kept for 1 to 2 days at 60°. The grains may be used at once again in fresh milk, and when the manufacture is finished they may be dried and kept, to be used again another time.

CHAPTER III

CHEESE

[Illustration:

Students making cheese in the University cheese factory, Madison, Wis.]

Most of the following pages on _Cheese_ were published in 1918 as a separate pamphlet to meet an urgent demand for brief directions along this line during the Food Conservation campaign. The copy has, however, been revised and new material has been added with the view of making this chapter more useful to those who desire to study in detail the manufacture of various fancy foreign types of cheese such as Edam, Swiss, Brick, Roquefort, etc., which are now made in this country in constantly increasing quantities.

For more complete directions in cheese making students are referred to "A B C in Cheese Making" by J. H. Monrad, and other technical works.

Cheese of a thousand different kinds is made, varying in properties and appearance from the solid, yet mellow and agreeable Cheddar cheese to the semi-soft, malodorous Limburger, the delicious, soft Neufchatel and Cream cheese, or the sweet Myseost of Norway. In India cheese was made centuries ago; to-day it is produced the world over, in the caves of the Swiss Alps and in the most modern and scientific American cheese factories and laboratories. Of these myriad types we can here describe only a few.

Cheese may be classified into that made with rennet and that made without. Of cheese made with rennet some is what is called hard, some soft.

The English and American _Cheddar_—the common _American cheese_—the _Dutch Gouda_ and _Edam_, the Swiss _Gruyere_, and the Italian _Parmesan_ are all hard cheese made with rennet. As examples of the soft varieties may be mentioned the French _Camembert_ and _Brie_, _Cream_ and _Neufchatel_ cheese. In a class by themselves are such cheeses as the French _Roquefort_, the English _Stilton_, and the Italian _Gorgonzola_, their peculiar flavors being derived from molds implanted in the curd.

[Illustration]

When cheese is made without rennet, the milk is allowed to curdle by natural acidity or it is in some other way made acid. Among the varieties made by this method the common _Cottage_ cheese is the best known.

For many years imitations of foreign varieties such as Swiss and Limburger have been made in Northern New York and Wisconsin. As a result of the war and the cutting off of foreign cheese imports, the State of Wisconsin has built up a large business in these fancy varieties. New types have lately been added, as the _Romano_, _Riggiano_, and _Myzethra_, which are of Italian and Greek origin. Some of these are made of whole milk, some of partly-skimmed milk, and others of the albumin of the whey.

Let us briefly review the characteristic features in the making of the older types.

CHEDDAR CHEESE

For a hundred years or more this famous cheese has been made and marketed at the village of Cheddar near Bristol, England.

In the middle of the nineteenth century a farmer in that neighborhood, Joseph Harding of Marksbury Vale, systematized the manufacture and it was his method that became the model for cheesemaking in America. In this country it was first made in Herkimer County, N.Y., where Harry Burrell not only made cheese for the home market, but also exported to England, and his son, David H. Burrell, at Little Falls later developed the machinery which became the standard for the American and Canadian cheese factories.

The factory system by which cheese was made from milk brought together from several farms, originated near Rome, N.Y., and soon cheesemaking became an important industry throughout Central and Northern New York whence it spread into Pennsylvania, Ohio and the West, as well as to Canada. To-day Wisconsin makes more cheese than all the other states together and Canada largely supplies England with Cheddar cheese of excellent quality.

[Illustration:

Joseph Harding, who systematized the making of Cheddar cheese in England]

[Illustration:

David H. Burrell, who introduced laborsaving machinery and supplies in the cheese factories]

[Illustration:

Jesse Williams, father of the American factory system]

The Factory System

The milk is delivered in the morning by the farmers at the factory and is weighed and strained through cheese-cloth into the cheese vat. When it is all in the vat it is warmed to a temperature of 86° F. by letting steam into the water surrounding the bottom and sides of the jacketed vat.

[Illustration:

A measuring glass and an accurate thermometer are indispensable]

[Illustration:

The Marschall rennet test]

=Ripening.=—The milk should be slightly acid, not noticeably sour, yet sufficiently ripened for the proper fermentation to take place in the process that follows. The best cheesemakers regulate the ripening by adding a starter to the sweet milk and allowing the

lactic acid bacteria to multiply in the milk until a _Rennet Test_[6] or _Acid Test_[7] shows that the desired degree of acidity has been reached. The starter may be sour whey or preferably prepared from sweet skim milk or whole milk with a commercial lactic acid culture as described in Chapter I under _Ferments_ and _Buttermilk_. From 1% to 2% starter is usually sufficient. An acidity of .18% to .20% or 2½ degrees on the Rennet Test is usually desired before the rennet is added.

[Illustration:

Christian D. A. Hansen, inventor of commercial rennet extract]

[Illustration:

Blowing up the rennets to dry them]

=Adding Color and Rennet.=[8]—If the cheese is to be colored, from 1 to 2 ounces of liquid cheese color (Annatto dissolved in an alkali) per 1,000 lbs. of milk is now added and thoroughly mixed into the milk which is then set with rennet. Three ounces of a standard rennet extract to 1,000 lbs. of milk is usually sufficient. Enough should be used so that the milk will show beginning coagulation in 10 to 15 minutes and be ready to cut in 30 to 40 minutes.

The extract should be diluted with ten times as much water and is then poured into the milk under vigorous stirring so as to be thoroughly distributed and incorporated in the whole mass.

Owing to the scarcity of the raw material for rennet extract during the war, pepsin extracted from hogs' stomachs has been substituted in many factories and is used either in dry form or as a liquid extract instead of rennet extract.

With pepsin as the coagulant it is necessary to ripen the milk somewhat further than if rennet is used, in fact to the danger-point where a little more acidity is apt to do harm and produce a dry and crumbly cheese and loss of butter-fat in the whey. Most cheesemakers therefore prefer rennet when they can get it.

The rennet having been added, the milk is left undisturbed until a firm curd has been formed. When the curd breaks or splits sharply before the finger pushed slowly through it, it is ready to be "cut."

[Illustration:

Curd knives]

=Cutting.=—Two sets of curd knives are used, each consisting of a metal frame in which tinned steel blades are hung, in one vertically and in the other horizontally. The vertical knife is first carried slowly through the curd lengthwise and crosswise; the horizontal set of blades is then moved carefully through the length of the vat. When the cutting is over, the entire mass should be in cubes about half an inch square.

The whey that begins to separate out should be clear and yellow. Milky whey is a sign that the butter-fat is escaping in it; the curd has been broken up too violently. In curdling, the casein encases the butter-fat and the object of the breaking up of the curd in the vat is to expel the whey but retain the fat in the cheese.

="Cooking" the Curd.=—Gentle heat is now applied to raise the temperature gradually to 98° or 100° in the course of about 30 minutes. Meanwhile the small pieces of curd are kept floating in the whey by gentle stirring with a rake and the hands, and are not allowed to pack at the bottom of the vat. The heating is easily regulated by opening the steam valve little by little. Through the "cooking" the pieces of curd shrink to some extent and are hardened so that they will gradually stand livelier stirring without losing butter-fat. After the cooking the curd is left for an hour or so in the whey for a slight acidity to develop and it is then shoved toward the sides of the vat and the whey is drained off. Here again the "Acid Test" may assist in determining when the whey should be drawn.

[Illustration:

Cutting the curd]

=Cheddaring or Matting.=—After thorough draining, the curd is packed together in the bottom of the vat or on a "sink" provided with a false bottom covered with cheese-cloth. After fermenting for 10 or 15 minutes it is cut into large pieces which are again packed together for further matting. The exact condition to be attained can be determined only by experience.

[Illustration:

“Cheddaring” or “Matting” the curd]

A simple test, the “Hot Iron Test,” may, however, help the cheesemaker to judge of this point. A handful of curd squeezed together and touched to a hot steam pipe or an iron rod heated almost red-hot in the fire under the boiler, and slowly withdrawn, will leave threads sticking to the iron. Depending upon the maturity of the curd, the threads will break at a length of from ½ to 2 inches. Usually fermentation is considered sufficient when threads 1½ inches long are formed by this test.

[Illustration:

Curd mill]

=Salting.=—The matting is then interrupted by breaking up and salting the curd. This can be done by hand or by a curd-mill which cuts or breaks up the curd and permits a thorough mixing in of the salt. Two or three pounds of salt to one hundred pounds of curd, or the curd from 1,000 lbs. of milk, is the usual ratio.

=Pressing.=—Stirring and cooling the salted curd to about 80° F. makes it ready for packing into the hoops in which it is to be pressed. The hoop is usually a cylinder of heavy tin with a “follower” of wood on which the pressure is applied. Before the curd is put in, the hoop is lined with cheese-cloth which remains on the cheese, when it is taken out. The press mostly used in the factory is the continuous pressure “gang-press” in which a number of cheeses can be pressed at the same time.

=Curing.=—After 18 hours’ pressure the cheese is taken out of the press and out of the hoop, weighed and placed on a shelf or table in the curing room. For the first week or ten days it is kept at a temperature of about 70°, later the cheese is removed to a cooler room and possibly placed in cold storage. Usually it is paraffined to prevent too much drying and cracking of the rind.

[Illustration:

Filling the curd into the hoops]

To cure a first-class Cheddar cheese takes from three to six months, but most of the American cheese is made to cure much more quickly and is eaten two to four months old. Indeed, it is generally shipped from the factory eight to ten days old and whatever further curing it gets is in the warehouse of the commissionman or in the grocery store.

[Illustration:

The Gang press]

=Form, Size and Packing.=—The old style American cheese is cylindrical, about 14 inches in diameter, and varying in depth to weigh between 60 and 80 pounds. Various other forms are now often made, square and long or in fancy shapes, such as a ball or a pineapple. Aside from such freaks, which have never become very popular, other deviations from the large, standard, American Cheddar, are also made to a considerable extent. People who have visited the beautiful National Dairy Shows held in turn in Chicago, Springfield, Mass., and Columbus, O., the National Milk and Dairy Farm Expositions of New York City, the Ontario Provincial Fair held each year at Toronto, or the annual State Fairs in New York, Wisconsin, Michigan and other cheesemaking sections will have in mind first the prominent exhibits of the regular Cheddar, showing a uniformity in texture, form and taste that is really remarkable. But one will also admire the variety of other forms. There are the _Flats_ or _Twins_, packed two in a box and weighing together the same as one _American_; the _Young Americas_ packed four in a box; the _Longhorns_ of six to eight inches in diameter; others made like a loaf of bread and creased so that a pound or two may be cut off fairly accurately, etc.

[Illustration:

Taking the cheese out of the press]

The _Giant Cheeses_, weighing five to six tons, occasionally exhibited and cut up at World Fairs and on similar occasions are, like the pineapple cheese, a curiosity rather than an industrial product.

One of the best forms, in the writer’s opinion, is the small 5-lb. cheese, proportioned exactly like the large American. This makes a suitable size for an average family, the members of which have learned to appreciate a good cheese. If it is made smaller, too much is lost in the rind; if larger it gets too old before it can be consumed by one family.

[Illustration:

Curing room]

The larger cheeses are usually packed in neat, snug-fitting elm-wood boxes, with thin “Scale Boards” on the top and bottom of the cheese, the smaller ones in paraffined pressed pulp or pasteboard boxes.

=Cleaning the Vats and Utensils.=—Like every other place where milk and its products are handled, the cheese factory must be kept scrupulously clean. Vats and utensils should be rinsed first with cold or lukewarm water or whey, then scrubbed with boiling hot water and if necessary with soda, soap, or washing powder. The surroundings should be kept neat and attractive, and the cheesemaker must see that the transportation cans are kept clean by the farmers and the milk delivered in good condition.

[Illustration:

Cheese box]

=Yield.=—The yield is around 10% of the milk. To make a pound of fresh cheese takes from nine to eleven pounds of milk. In curing, a part of the weight is lost by evaporation, but this loss is reduced to a minimum by paraffining.

In some localities an increased yield is obtained by washing the curd and making it absorb all the water it can hold. The process is not commendable and while it may sell to some extent, in certain markets where a soft, fresh cheese is liked, “washed” or “soaked” curd cheese can never compare favorably in quality with a well-made, firm Cheddar cheese that is mellowed down by long-time curing to a consistency so it will fairly melt in your mouth.

=Composition.=—The American cheese contains almost all the casein and the butter-fat of the milk, besides such portions of the milk-albumin, milk-sugar, and mineral matter as are held in the water or whey which is retained in the cheese. In round figures average American cheese contains equal parts of casein, butter-fat and water, 30 to 35% of each. In order to protect the honest maker and the consumer and prevent “soaking” of the curd to an extent that may be considered fraudulent, the dairy laws of the State of New York limit the contents of water permissible to 40% and 42% respectively for certain classes of cheese.

=Qualities.=—A good Cheddar cheese should be mellow, yet solid, without holes, and of an agreeable taste, neither sharp nor bitter. Cheese can be made of skim milk, but it is hardly palatable. In the fall of the year, when the average milk is rich in butter-fat, 1% or 2% butter-fat may be taken from the milk and the resulting partly-skimmed milk will still make a fairly good cheese, hardly distinguishable from full cream cheese. Under the laws of the State of New York it must, however, be marked “Skim Milk Cheese.”

Cheese Made from Pasteurized Milk

From time to time attempts have been made to make Cheddar cheese from pasteurized milk. If the milk is heated to 145° only, and held for 30 minutes at such temperature, its property to form a firm curd with rennet is not destroyed and it will make a fine cheese, but if it is pasteurized at a higher temperature it will not curdle firmly until it is ripened or otherwise brought back to the condition required for satisfactory action of the rennet ferment. Thorough ripening with a pure culture starter will do it, or an addition of muriatic acid will accomplish the same in a shorter time, but care must be taken not to use too much, which would make the cheese dry and crumbly. Dr. J. L. Sammis and A. T. Bruhn of the Wisconsin Dairy School worked out the problem and systematized a process which is described in Bulletin 165 of the U. S. Department of Agriculture and by which it is claimed a first-class cheese can be made regularly from thoroughly pasteurized milk.

Making Cheddar Cheese on the Farm

[Illustration:

American outfit for farm cheese making]

[Illustration:

Plain wooden vat and curd mill]

It takes quite a little experience to make a good Cheddar cheese and, unless one has the time and opportunity to study it and make it an every-day practice, it is not as a rule advisable to attempt making Cheddar cheese in the home from the milk of one or a few cows.

The amateur will usually find it easier to make Neufchatel or Cream or Cottage cheese for home use or for the home market.

[Illustration:

Danish kettle and cheese vat]

If Cheddar cheese is to be made regularly it is best to get an outfit consisting of a small boiler and a jacketed vat, although cheese may be made in a plain wooden tub or any other convenient vessel. The double bottomed vat generally used in American as well as in Danish dairies facilitates both the heating of the milk before setting and the “cooking” of the curd in the whey after cutting. Either low pressure steam, or—better—water heated by steam, is introduced in the space between the outer, wooden bottom and the inner, tinned steel or copper bottom. If it is cool the milk should be warmed to 86° F. In the summer it may be warm enough as it comes in, fresh from the cow. If not, heat it by steam or by setting it in a “shot-gun” can in another vessel of hot water, stirring frequently, until the thermometer shows 86°. It may be well to add a little buttermilk or sour whey from the preceding day, or a pure culture starter made with Buttermilk Tablets, not to exceed 1% or 2%.

[Illustration:

Cutting the curd]

If it is desired to make colored cheese add a teaspoonful of liquid cheese color, or ½ cheese color tablet dissolved in warm water, to 100 pounds of milk, more or less according to season and the shade of color desired in the cheese.

Next add the rennet. Where cheese is made from less than 500 lbs. of milk Rennet Tablets are handy, one tablet to 80 or 100 lbs. For less than 50 lbs. of milk, Junket Tablets may be used, one to a gallon. Dissolve the tablet, or tablets, or fraction of a tablet, as the case may be, in _cold_ water and stir the solution well into the milk, making sure of thorough mixing. Let stand covered for half an hour until a firm curd is formed. Cut or break the curd very carefully with a big knife or spoon or home-made fork with wires across the prongs, imitating as far as possible the operation with curd knives in the factory.

[Illustration:

Taking the temperature of the milk in a shot-gun can]

[Illustration:

Curd fork]

[Illustration:

Mold or “Hoop”]

“Cook” the curd as in factory cheesemaking. If steam is not available, allow the curd to settle and dip off some of the whey which is then heated and poured back on the curd so as to raise the temperature of the whole mass about 2 degrees. Repeat this several times, gradually raising the temperature to 100°, a few degrees at a time.

Keep the curd gently stirred up and floating in the whey and do not allow it to lie on the bottom of the vat long enough to pack firmly together, stirring once in a while until by smell and taste (if not also by acid or hot iron tests) it appears to be sufficiently fermented for the whey to be drawn, a condition that can only be learned by experience. This will be about two or three hours from the time the rennet is added.

[Illustration:

Diagram of lever press]

[Illustration:

Combined screw and lever press]

Draw the whey and press more out of the curd with the hands. Let the curd mat and break it up alternately several times; finally crumble and pulverize it and keep it stirred with the hands, adding salt at the rate of three to four ounces to the curd from 100 lbs. of milk and continuing the stirring until the curd is cooled down to below 80°, when it should be packed into the hoop and put to press.

This salting and cooling may take another hour. The hoop may be made of wood or heavy tin of any size desired, with a loose follower of wood. The sides and bottom should be perforated to allow the whey to escape. Or it may be a cylinder without top or bottom, placed on a corrugated piece of board. Line the hoop with cheese-cloth before putting in the curd.

[Illustration:

Upright factory and dairy cheese press]

For pressing, a home-made lever-press, as outlined in the diagram, may be made of a plank or bar, one end of which (_C_), is stuck under a piece of a board nailed on the wall while at the other end a weight (_K_) is applied which may be moved in and out to regulate the pressure. The hoop is placed under the plank at the fulcrum (_K__{1}) near the wall. If a compound lever-press or a screw-press is available it is better. It is important that the pressure is applied straight so as to make the cheese even and not one side lower than the other. Begin with light pressure and increase it gradually every hour until at night the full pressure is applied. After an hour take the cheese out and turn it in the hoop, then return it to the press and at night apply full pressure. The next morning take it out and weigh it and place it on the shelf to cure in a room of moderate temperature, turning it every day. After a couple of weeks it may be removed to a cool cellar and rubbed with grease. In two to three months it should be sufficiently matured for consumption.

OTHER TYPES OF HARD CHEESE MADE WITH RENNET

[Illustration:

A variety of domestic and foreign cheese made at the dairy school of the University of Wisconsin]

In the manufacture of the Dutch Gouda, the Danish Export, and other similar types, the “cooking” and matting of the curd, characteristic of the English and American Cheddar, are more or less omitted. Otherwise the process and the result are not greatly different. They are all “hard” or solid cheese of the same class, though there are hundreds of varieties in different localities, each with some peculiarity of its own.

[Illustration:

Gouda cheese]

=Gouda Cheese.=—The _Gouda_, like the _Danish Export_ cheese, is made from whole or partly-skimmed milk which is set with rennet at 90° F. and is coagulated, ready for cutting, in fifteen to twenty minutes. The curd is broken with the “lyre,” so called, a frame on which piano wires are suspended. The curd is but slightly “cooked” and the whey is drawn while still sweet. After being pressed with the hands in the vat to squeeze out the whey the curd, still quite warm, is put into wooden molds and worked and squeezed in them with the hands for half an hour to eliminate more whey, when the mold is placed in a regular press for 12 to 18 hours. To salt it the cheese is placed in a strong brine where it remains for several days. It is then put on the shelf in the curing room where it is turned and rubbed daily and in four to six weeks it is marketed. The cheese is about 10 inches in diameter by 4 to 5 inches high.

[Illustration:

The Lyre]

=Edam Cheese.=—The ball-shaped red _Edam_ is also made in Holland by a similar method to that of the Gouda.

Fresh milk is set at from 90° to 93° F. in summer and up to 97° in winter,—colored to a rather high yellow with Annatto. Add sufficient rennet to coagulate the milk in 8 to 15 minutes. Cut curd carefully with the “lyre” and break with fork into very fine pieces, as small peas. Leave to settle for 3 to 4 minutes, putting cover on the vat if the temperature in the room is below 60°. When settled, the curd is gently pushed into a heap which takes 5 to 6 minutes and the whey is removed with a dipper. Weight is applied for 5 minutes and the tub or vat is tipped so the whey will drain off while the curd is held back with the dipper. This pressing is repeated twice more for 4 and 3 minutes respectively.

[Illustration:

Curing room in a Gouda cheese factory]

The curd should now be elastic and firm and show a temperature, in winter of at least 83°, in summer at most 90°. If necessary the temperature is regulated by pouring hot whey (not exceeding 104°) or cold water over the curd.

The mold is then placed in the vat and two handfuls of curd put in which is squeezed and worked thoroughly with the hands. More curd is added and worked in the same way and this is repeated until the mold is full with a large top on, which is pressed with the hands for 4 or 5 minutes, turning the cheese 3 or 4 times and opening the drain holes if plugged up. Some makers sprinkle a teaspoonful of fine salt in the bottom of the mold, but in warm weather it is better to work in a quarter of an ounce of salt. This work must be done quickly so the curd will not cool.

[Illustration:

Mold for Edam cheese]

When thus formed the cheese is dipped for 1 or 2 minutes in fresh whey heated to 126° (in winter 131°) and pressed with the hands in the mold for another 2 minutes when it is carefully wiped off by rolling on a fine cloth to remove the last drop of whey. The cheese is then wrapped in a fine cloth, placed in the mold and put to press, in the Spring for 5 to 7 hours, later in the year for 12 hours. The cloth is now removed and the cheese is put in a larger mold which is placed in a water-tight salting box provided with a cover and a drain-hole in one end. The first day a pinch of salt is put on the top of the cheese and the next the whole cheese is rolled in damp salt, turned and put back in the mold, a liberal quantity of salt being placed on the top. This is repeated every day until the cheese from being soft and elastic becomes hard which as a rule takes 8 to 10 days for a 4 lb. and 12 days for a 10-12 lb. cheese. Finally the cheese is left a few hours in the brine collected in the box, washed, wiped and placed on the shelf in the curing room.

The curing room should be light and well ventilated, never above 72° nor below 45°. Windows must not be opened to admit dry wind or moist air. If too dry the cheese will crack and if too moist it will be covered with deleterious yellowish red fungi. The cheese is turned daily the first month, later every other day or twice a week. When 24 to 30 days old the cheese is soaked for one hour in water of 68 to 77°, washed with a brush, dried for 20 to 40 minutes in the sun and returned to the shelf. This is repeated two weeks later and then the cheese is painted with linseed oil and left on the shelf until shortly before shipping when it is scraped with a sharp knife and painted according to the demand of the particular market for which it is prepared; yellowish with Annatto for England and Spain, red with Turnsole for other countries. When dry it is rubbed with a little butter and red color.

=Swiss Cheese.=—The Swiss Gruyere or Emmenthal also belongs to this class. It is characterized by its form and size, being large, round and flat, weighing 100 to 140 lbs. or more, and by the large holes which are wanted in Swiss, but not tolerated in American or Dutch cheese. It was formerly supposed that first-class Swiss cheese could only be made in the Alps, but very good imitations have long been made in Northern New York and in Wisconsin. Besides in the usual large round form, the same as the genuine imported Emmenthaler, American Swiss or “Switzer” is also made in _blocks_, six inches square and twenty inches long, weighing 25 to 30 lbs.

Until lately Swiss cheese has been made in the old-fashioned way, the factory and tools being of the simplest description. The milk was heated in a copper cauldron hanging on a crane, enabling the cheesemaker to swing it on or off the fireplace. Nowadays the kettle is usually jacketed and heated with steam. The round form is still preferred to the American cheese vat, however, as it adapts itself better to the peculiar method of handling the curd.

[Illustration:

Swiss cheese]

The milk is set with rennet at a temperature of 90° F. in summer and 95° in winter, sufficient rennet being used to make a firm curd in thirty to forty minutes. But very little color is added. The curd is cut with a long, sharp wooden knife, the “cheese sword,” first one way into sheets, then, as soon as the cuts stand clear, beginning to expel the whey, crossways, into vertical sticks, two inches square.

[Illustration:

Scoop]

[Illustration:

Cheese sword]

[Illustration:

Cutting the curd with the scoop]

[Illustration:

Tools for stirring the curd]

No horizontal knife is used, but a few minutes after the last vertical cutting the curd is further broken by the “scoop,” a wooden spoon or ladle about eight inches long, thirteen inches wide, one and one-half inches deep, and provided with a short handle. Standing at one side of the kettle, the cheesemaker scoops off a layer from the top and, drawing the scoop towards himself, drops the pieces of curd close to the side of the kettle. This movement is repeated, at first slowly, then faster, and soon the whole mass of curd is moving, the pieces cut off going down along the side of the kettle and the rest of the sticks sliding upward along the other side, to be attacked by the scoop as soon as they come to the top. All the curd having been cut into square pieces, it is further broken by the stirrer, a stick at the lower end of which a few cross sticks or wings of brass wire are fixed, the whole mass being kept in constant motion.

=Cooking the Curd.=—After breaking up the curd to the size of peas or beans, the stirring is discontinued for about ten minutes, when it is begun again and the kettle is turned over the fire, or steam is applied, to heat the curd to 140° under constant stirring which is continued for 45 to 60 minutes after this temperature has been reached. The condition of the curd is judged by squeezing a handful and noticing its elasticity and consistency. It is important to stop stirring at the right moment. More whey is expelled in making Swiss cheese than for Cheddar cheese.

The cooking and agitating having been finished, the mass, which now consists of grains the size of wheat, is once more stirred up with such force as to make it form a funnel at the center and it is then left at rest for five to ten minutes.

The curd, forming a rather solid cake at the bottom of the kettle, is now lifted out without being broken. One end of a large piece of cloth is folded around a flexible rod. Bending over the kettle the maker takes hold of both ends of the rod and gathering the other end of the cloth between his teeth, pushes the rod down along the farther side of the kettle, letting it follow the bottom towards himself until the whole mass of curd is gathered in the cloth, when it is lifted out of the kettle and placed in the hoop on the press table. The hoop can be enlarged or diminished to take care of a varying amount of curd which is put into it in the same solid cake as formed in the kettle without being broken. Pressure is applied, at first, gently, later heavier and after half an hour the cheese is taken out, turned and provided with fresh bandage, put back into press and left till the next day.

[Illustration:

In Swiss cheese making the curd is lifted out of the vat with a strong cloth]

Curing and Salting.—The cheese is first placed in a curing room above ground and heated in winter. After a few weeks it is removed to the cellar. Sometimes three to five cheese are piled one on the top of the other for a few days with a few handfuls of salt between them. The salting proper is done by rubbing and brushing dry salt and the brine formed from same into the cheese,—altogether 4 to 5 lbs. of salt to 100 lbs. of cheese. Every day it is rubbed with a dry rag and the cheese is turned and salted on the other side until the salt is thoroughly incorporated.

[Illustration:

Swiss cheese press]

The cheese is cured for at least 100 days in the factory and is usually stored for another three to six months by the dealer before it is ready for the consumer.

=Roquefort.=—The French _Roquefort_ is inoculated with a mold from stale bread which spreads through the cheese and produces the peculiar flavor of this type. It is made from sheep’s milk and was formerly cured in cool subterranean caverns, but now in elaborate curing houses. In this country imitation Roquefort is made of cow’s milk and cured in cold storage.

It should be remembered, however, that sheep’s milk is very rich in fat and that a rich Roquefort that will compare favorably with the genuine cannot be made from cow’s milk without an addition of cream if sheep’s or goat’s milk is not available. In France a small addition of cow’s milk to the sheep’s milk—not to exceed 10%—is often used.

Around Roquefort a milk ewe produces on an average 135 lbs. of milk a year, which makes up to 35 lbs. of cheese.

[Illustration:

Milking the ewes at Roquefort, France (G. Ellbrecht)]

The milk is set at about 80° with rennet sufficient to coagulate it in 1½ to 2 hours. To cut or break and stir the curd, tools similar to those used in the manufacture of Dutch cheese are employed and stirring is continued until the pieces of curd are about the size of peas when the whey is dipped off and the curd is further broken with the hand and placed on a cloth to drain. In fifteen minutes it is ready to be put into the hoops which are either of glazed stoneware or perforated tin, 8 inches in diameter by 4 in. high.

Ground stale, moldy bread is sprinkled in the curd as it is put into the hoop, at the rate of 1 part of bread to 10,000 parts of curd. This moldy bread is prepared from 2 parts of wheat flour and 1 part of rye flour leavened with sour yeast and vinegar and baked hard. The loaf is placed in a dark, moist cellar to mold. In six weeks it is penetrated with mold when it is dried at 86° and pulverized, forming the powder used for inoculation into the cheese-curd.

When the hoops are filled they are placed in large wooden boxes at a temperature of 65° to 70° for the whey to drain off. The first few days the cheese is turned three times a day, later once a day, and when five days old it is brought into the curing room where it remains until it is firm enough to be shipped to the large cold storage establishments, where it is taken care of until ready for the general market.

In the “caves” a high degree of moisture, a low temperature—40° to 50°—and pure air are essential conditions.

The cheese is first _salted_ by being rubbed repeatedly with salt on all sides. The slime forming on the surface is brushed or scraped off so as not to prevent the admission of air, which is essential to the curing. In order to further facilitate the penetration with air the cheese is now _pricked_ with numerous needles by means of a machine and placed on the shelf in the cave where the proper moisture and temperature are maintained.

Various fermentations are now developing, one after another, regulated by scraping, ventilation, etc., until in six to twelve weeks the cheese is ready for the market and is packed for shipment in paper or in tinfoil and in wicker baskets or airtight boxes, according to destination,—for home consumption or for export.

[Illustration:

Curing room in a Roquefort cheese factory (G. Ellbrecht)]

=Parmesan Cheese= is an Italian cheese made mostly in the Valley of the River Po and named from the City of Parma. It is produced from partly-skimmed milk and is allowed to become hard and dry, being used grated with macaroni.

The milk is set with rennet at a comparatively high temperature, about 95° F., and when it is firmly curdled it is broken up and stirred rather vigorously, which makes the curd fine and dry. Color is now added—powdered _Saffron_—at the rate of 0.5 gram to 100 kg. milk. The curd is cooked slowly under constant stirring to a temperature up towards 100° when the whey should be perceptibly acid.

The curd is then allowed to settle in the round kettle and when fairly firm it is lifted up in a cloth, the same as in Swiss cheesemaking. The mold is also much the same as the Swiss and the curd is but slightly pressed. In the course of the day the cheese is turned once or twice and put into fresh cloth. The next day it is put into the curing room when it is rubbed with salt. In a few months the cheese is cured and is then scraped and polished with linseed oil. Sometimes it is kept in storage two or three years in a dark room at a temperature of 63° F. The composition averages: 32% water, 21% fat, 41% nitrogenous matters and 6% ash.

[Illustration:

Caccio Cavallo]

=Caccio Cavallo= is made in Southern Italy of a form almost like a beetroot. The milk is set with rennet at about 95° F. and after the curd has been broken up the whey is dipped off and heated to boiling when it is poured back on the curd. The mass is then allowed to ferment eight to fourteen hours according to the temperature of the air. The quality of the cheese depends largely on this fermentation. The fermented curd is cut into pieces and submerged in boiling water and is then kneaded and formed into the

desired shape.

After lying in cold water for two hours and in brine for thirty hours it is dried and smoked until it attains a fine golden color. It is made in various sizes, from 5 to 20 pounds, and the yield is said to vary from 10% to 16% of the milk. Caccio Cavallo is eaten on bread as well as with macaroni and is much relished by the Italians.

=Limburger=, =Brick=, =Munster= and other similar semi-soft cheese of the proverbial strong flavor, originated in Belgium and Bavaria, but are now largely made in Northern New York and Wisconsin as well.

For Limburger the milk is not ripened as for Cheddar but is set with rennet quite sweet at a temperature of about 90°; the curd is cut rather soft, care being taken, however, not to lose butter-fat. The curd is but slightly “cooked,” to a temperature not to exceed 96°, and is not salted in the vat but is dipped out into perforated wooden boxes or molds about 5 inches square and left to drain without pressure. The cheese are placed edgeways like bricks on shelves and are rubbed with salt and turned every day until cured. During the curing process moisture exudes and a fermentation takes place which develops the well-known “Limburger” flavor. After eight or ten weeks the cheese is packed in paper and tinfoil and is ready for the market.

=Brick= cheese is something between a Cheddar and a Limburger, of a milder flavor than either, not as hard as the former but firmer than the latter.

The milk is slightly ripened and is set with rennet at 86° so as to coagulate in 20 minutes. The curd is “cooked” to 110° or more and is not allowed to “mat” as for Cheddar cheese, but is dipped out of the vat before much acidity has developed, into the molds, which are rectangular boxes without top or bottom placed on a draining table where the whey runs off.

The mold is usually 5 inches wide, 8 inches deep and 10 inches long. When it is filled with curd a follower is put on the top and a slight weight, a couple of bricks, on the follower. The cheese is turned a few times and the next day it is taken out of the mold and placed on the salting table. The salting is done by rubbing the cheese on all sides with salt which penetrates the curd and draws out moisture. This is repeated for 3 days and the cheese is then left to cure, being washed and wiped off every week to prevent molding.

Brick cheese is shipped one or two months old. It is wrapped in paper and packed twenty in a box.

=Munster Cheese= is very much the same as Brick except for the form, it being round, molded in a perforated tin hoop instead of the box used for Limburger and Brick.

SOFT RENNET CHEESE

The soft cheese made with rennet may be classified as _fresh_ and _cured_.

=Neufchatel.=—The fresh soft cheese of the _Neufchatel_ or _Cream Cheese_ type is easily made and may be produced in any house from a small quantity of milk. The milk is set at a comparatively low temperature, usually 72° F., with very little rennet, just enough to coagulate the milk in about eighteen hours. During that time a slight acidity develops in the milk. When it is firmly curdled it is carefully dipped on to cheese-cloth suspended on a frame, or into cotton bags where it drains overnight.

To make the cheese quickly a starter is sometimes used and more rennet employed. The milk is heated to 80° F., 25% starter and 7½ c.c. of rennet extract, or one rennet tablet per hundred pounds of milk, are added and the milk curdles in about 30 minutes.

After draining for a few hours the curd is gently pressed for a similar time. When the whey is fairly well expelled, the curd is kneaded or run through a meat cutter with a little salt, not more than 2½ oz. to 10 lbs. of curd. The outfit and the manipulation is essentially the same as described under Cottage cheese.

A superior quality is obtained by pasteurizing the milk and if that is done a pure culture starter should always be used. If the slow setting method is used a very small amount of starter, say ½%, is sufficient, but when the quick process is employed 10% to 25% may be added.

[Illustration:

Molding Neufchatel cheese]

To give it a good appearance for market, the cheese is molded in little tin molds very much like a quarter-pound baking powder can with open ends. The cylindrical roll of cheese is wrapped in parchment paper and tinfoil and is immediately ready for consumption. In an ice box it will keep for a week or so. Neufchatel cheese may be made from whole milk or partly-skimmed milk. The yield is from 10 to 20 lbs. out of 100 lbs. of milk.

=Cream Cheese= is usually made in the same way. A mixture of cream and milk containing about 10% butter-fat is used, though sometimes the cream is not added until the time of salting. The mold is square, 2½" × 1½" × 2" deep. These soft kinds of cheese are often mixed with chopped peppers, olives or nuts and make excellent sandwiches.

=Cured Soft Cheese.=—For _Cream_ or _Neufchatel_ cheese, made for curing, the curd is salted more than for fresh cheese, or the molded cheese is rolled in salt. For a week or two it is placed in a curing room on straw mats or the like where it ferments slightly before being wrapped and packed for shipment.

=French Soft Cheese.=—The many forms of French soft cheese as represented by the _Brie_, the _Camembert_, etc., are subjected to special fermentations which give to each its peculiar flavor. Attempts have been made to use pure cultures of the bacteria active in such fermentations and so reduce the art of cheesemaking to a more scientific process. But it has been found that any desired kind of cheese cannot be made simply by adding a culture of this or that bacterium to pasteurized milk. Of vastly greater importance for the development of the proper bacteria and flavor is the handling of the milk and the curd by the experienced cheesemaker. Inoculation with a pure culture alone does not make the special cheese wanted.

CHEESE MADE WITHOUT RENNET

[Illustration:

Mono-service jar]

=Cottage Cheese.=—Of the sour milk types the common _Cottage Cheese_ is the best known. It is made from skim milk which in a warm room will curdle when sour, whether rennet and a starter are used or not. The thick sour milk is heated to anywhere between 100° and 120° and dipped into bags of cheese-cloth hung up for draining. The next day light pressure is applied for 12 to 24 hours, when the curd is kneaded, slightly salted, formed into balls and wrapped in parchment paper or packed into jars. For this purpose paraffined paper jars are very practical.

The more the curd is heated in the whey the drier will be the cheese. Often it is improved by allowing the curd to become rather dry and then working new milk or a little cream into it, according to the use to which it is to be put—whether it is for bakers' stock or for the table.

Simple directions for making Cottage cheese are given in Farmers' Bulletin 850 and A. I. 17, issued by the United States Department of Agriculture from which we reprint the following and copy the accompanying illustrations:

[Illustration:

Pouring the curdled milk on cloth to drain]

"One gallon of skim milk will make about 1½ pounds of cheese. If the milk is sweet it should be placed in a pan and allowed to remain in a clean warm place at a temperature of about 75° F., until it clabbers. The clabbered milk should have a clean, sour flavor. Ordinarily this will take about 30 hours, but when it is desirable to hasten the process a small quantity of clean-flavored sour milk may be mixed with the sweet milk.

"As soon as the milk has thickened or firmly clabbered it should be cut into pieces 2 inches square, after which the curd should be stirred thoroughly with a spoon. Place the pan of broken curd in a vessel of hot water so as to raise the temperature to 100° F. Cook at that temperature for about 30 minutes, during which time stir gently with a spoon for 1 minute at 5-minute intervals.

[Illustration:

Lifting the cloth back and forth to facilitate draining]

"At the conclusion of the heating, pour the curd and whey into a small cheese-cloth bag (a clean salt bag will do nicely) and hang the bag in a fruit-strainer rack to drain, or the curd may be poured into a colander or a strainer over which a piece of cheese-cloth

has been laid. After 5 or 10 minutes work the curd toward the center with a spoon. Raising and lowering the ends of the cloth helps to make the whey drain faster. To complete the draining tie the end of the bag together and hang it up. Since there is some danger that the curd will become too dry, draining should stop when the whey ceases to flow in a steady stream.

[Illustration:

Pressing the curd]

“The curd is then emptied from the bag and worked with a spoon or a butter paddle until it becomes fine in grain, smooth, and of the consistency of mashed potatoes. Sour or sweet cream may be added to increase the smoothness and palatability and improve the flavor. Then the cheese is salted according to taste, about one teaspoonful to a pound of curd.

“Because of the ease with which the cheese can be made it is desirable to make it often so that it may be eaten fresh, although if it is kept cold it will not spoil for several days. If the cheese is not to be eaten promptly it should be stored in an earthenware or glass vessel rather than in one of tin or wood, and kept in a cold place.”

[Illustration:

Apparatus needed in making cottage cheese]

=Making Cottage Cheese with Rennet.=—In the bulletin mentioned a method is also given for making the cheese with rennet or pepsin. Junket Tablets make a convenient form of rennet to be used for this purpose.

The advantages claimed for this method are:

1. A finer textured and more uniform cheese.

2. The making requires less time and attention.

3. Losses of fat in the whey are reduced.

The process is the same as described above except that a solution of _Junket Tablets_ is added to the milk at the rate of one tablet to 100 lbs. of milk. For less milk use a fraction of a tablet, or dissolve one tablet in ten tablespoonfuls of water and use one spoonful of the solution for each 10 lbs. of milk.

If a starter is used the rennet solution is added immediately after the starter is put in; if no starter is used the milk is left for five or six hours at 80° F. to ripen before adding the rennet. The milk will curdle overnight.

After draining for thirty minutes on cotton sheeting the ends of the cloth are tied together and a weight is placed on top to press the curd gently until the desired consistency is attained.

Salt may be worked in at the rate of 2½ ounces to 10 lbs. of curd. If desired, add sweet or sour cream at the rate of ½ pint to 10 lbs. of curd or ¼ pint of cream to the product from 30 lbs. of milk.

It will be seen that Cottage cheese made with rennet is really the same as Neufchatel cheese, the only difference being in the form and packing or wrapping of the finished cheese.

=Snappy Cheese.=—By allowing the sour skim milk curd to ferment under careful regulation, a variety of sharp, snappy, more or less hard cheese can be made. Though there is no general demand for them, some kinds are quite popular in their own restricted localities. The Danish _Appetite cheese_ is only one of the many varieties which have as many names.

=Club Cheese= and similar varieties are made by grinding up old dry cheese with a little butter and packing the product in jars or other attractive packages. American, Roquefort, or any other well-known type may be used as the stock for these cheeses. Everywhere they are favorites in dining cars and lunch rooms.

[Illustration:

Milking the goat in Norway]

=Whey Cheese.=—In Switzerland the so-called _Zieger cheese_ is made from sour whey, the albumin being coagulated by heat and, with whatever butter-fat there may be left in the whey, skimmed off the top. In Norway _Myseost_ (“Ost” is Norwegian for

cheese) is made by boiling down whey almost to dryness. If goat milk is available to mix in, it improves the cheese. The main substance is sugar of milk and the cheese has a sweet, syrupy flavor.

MILK SUGAR

The by-product, sugar of milk, is produced by acidifying the whey, heating to boiling and neutralizing with lime until the albumin is coagulated. It is then filtered out and the clarified liquid is concentrated in vacuum. From the thick syrup the sugar is allowed to crystallize out, leaving the salts or mineral matters (milk-ash) in the remaining liquid. The use of milk-sugar is limited to medicinal purposes and for modifying milk for infants. The production is therefore not very extensive.

CASEIN

In a number of creameries casein is produced from skim milk by precipitating it with an acid and drying and pulverizing the precipitate. Casein is widely used as a substitute for ivory, in billiard balls, buttons, etc. It is also used as glue, and as a binder in paints.

MILK POWDER

The production and use of dry milk has increased enormously during the last few years and the processes of manufacture have been improved well-nigh to perfection. There are several methods practiced, the most important being the following:

The _Just-Hatmaker_, in which a large metal drum or cylinder revolves slowly in a tank of milk. The drum is heated by steam inside and, as it rolls out of the milk, the metal surface picks up a thin film of milk which quickly dries and is removed by a scraper.

The _Eckenberg_ process employs vacuum evaporating pans, like those used for making condensed milk and maple syrup.

The _Merrell-Soule_ Company's method consists in driving a blast of hot air into a fine spray of milk, which at once reduces the milk to a fine powder.

In the "_Economic_" process the milk is dried by hot air the same as in the Merrell-Soule method, but in dropping through a tower from a height of some 30 feet the milk meets several blasts of air of different temperatures. It is claimed that in this way alone rich milk and cream may be reduced to a powder without injury to, or change of, the original fat globules.

=Skim Milk Powder.=—Beautiful skim milk powders are now made which dissolve perfectly in water. Containing, as they do, the extremely nourishing constituents of the fatless milk in a most palatable form, they can be used in baking and in many food products to great advantage.

=Whole Milk Powder.=—Until recently dried whole milk was not produced of good keeping quality as the butter-fat had a tendency to become rancid before many months. But improvements are constantly being made and milk powders of every degree of richness bid fair to take the place of fresh milk on board ships and in other places where milk must be kept a long time before being used.

In many new food preparations of value, milk powder is filling a long-felt want. Dissolved in 8 or 9 times as much water, milk powder makes a liquid almost identical with pasteurized fresh milk.

It has already been mentioned under the chapter on "Cream" and under "Ice Cream" how skim milk powder and unsalted butter, _emulsified_ in a suitable amount of water or milk, make an excellent material for ice cream.

CONDENSED AND EVAPORATED MILK

Milk cannot be boiled down in a common open kettle or steam boiler without being scorched. Evaporating or condensing is therefore usually done in a vacuum pan at a low temperature. Condensed to one-third of its volume and excluded from the air by canning, milk will keep well for months, and has many uses as a substitute for fresh milk. Often sugar is added as a preservative, and where sugar would be added anyway, as in coffee, ice cream, etc., this is unobjectionable.

For purposes where sugar is not wanted, unsweetened condensed or evaporated milk is on the market, so carefully made that the taste of the original milk is hardly changed at all by the process. When water is added in the proportion of two parts of water to one of the evaporated milk, the fluid obtained excels even that from milk powder in its resemblance to fresh milk.

WHEY

Whey is a by-product in cheesemaking. Usually it is fed to hogs and especially together with grain or bran it makes an excellent food for them. But whey is also prepared for human food. In the hospital or in the home it serves as a substitute for milk when a mild diet of easily digested food is temporarily required for a weak stomach. For such purposes it must not be allowed to become acid as in cheesemaking, but should be prepared as the chief product from sweet new milk or freshly separated skim milk. The sweet milk is set with rennet—one Junket Tablet, dissolved in cold water, to a quart of milk—at a temperature of 90° to 100° F. As soon as a firm curd is formed it is carefully broken up and transferred to a strainer of cheese-cloth. Unless it is to be used at once, the whey strained off should be immediately cooled to 50° or lower. If left at a higher temperature it will soon become sour. A teaspoonful of limewater to a quart, or a pinch of soda, will help to keep it sweet. Still, in any event, it should not be kept long, but prepared fresh when required.

CHAPTER IV

MILK AS A FOOD

Milk is first of all the food for the young,—until a certain age the only food, and a perfect food. It contains but little refuse or waste and is under favorable conditions almost wholly digestible.

NUTRIENTS

All foods contain certain groups of nutrients which may be classified according to various functions in nutrition and their chemical composition.

=Protein.=—The protein group of nutrients contains nitrogen and is necessary for building up the tissues of the body, the muscles and the tendons which also contain nitrogen. Only by this group can tissues wasted by constant wear and tear be rebuilt. Proteins are the flesh-forming group. To some degree the proteins or albuminoids are also active in producing fat in the body, but the other groups of nutrients, especially the fats, also contribute.

=Fats and Carbohydrates.=—Another important function of food is to produce and maintain the animal heat. The main sources of this necessity are the fats and the carbohydrates, so called because they consist of the element carbon combined with oxygen and hydrogen, the last two in the exact proportion in which they are combined in water. All of these three groups furnish the fuel, so to speak, for the body, but they are not equal in this respect. Pound for pound, when burned in the body, the fats yield 2¼ times as much heat as protein or the carbohydrates.

=Mineral Matters.=—Finally there are in all foods the mineral matters, a group containing a number of salts which are indispensable because they are constituents of every part of the body. Phosphate of lime, for instance, makes up one-half of the substance of the bones, and the sulphates and chlorides of potash and soda, iron, etc., are everywhere present in smaller quantities. No food in which any of them is lacking is complete.

=Relation.=—The value of a food depends largely upon the relation of one group of nutrients to another. Proper nutrition can only be obtained when a sufficient amount of flesh-forming as well as of heat-producing nutrients are present, when the “nutritive ratio” is properly balanced for the particular purpose in view, be it the growth of the child, the maintenance of the body, the restoration of matter consumed by labor of body or brain, or the supply of heat to make up for cold surroundings.

=Milk contains all= of these groups of nutrients. The protein is represented in milk by the casein and albumin, the fats by the butter-fat, the carbohydrates by milk-sugar, and the mineral matters by the milk-ash. Human milk contains them in a perfect proportion for infants, and for all purposes of nutrition cow’s milk may be used to make up a “balanced ration,” if not alone, then in connection with other food.

=Nutritive Ratio.=—As we said before, the “nutritive ratio” of a food means the ratio of its flesh-forming constituents—proteins—to its heat-producing nutrients—carbohydrates and fats. Cow’s milk, containing 3.25% protein, 4% fat and 5% milk-sugar, has a nutritive ratio of 1 : 4.3, i. e., 1 part of protein to 4.3 parts of heat-giving nutrients, counting the fat equal to 2¼ of carbohydrates (multiplying the 4% fat by 2¼ makes 9, added to the 5% of sugar, makes 14; 3.25 to 14 equals 1 to 4.3). Skim milk, containing 3.4%

protein, 0.2% fat, and 5.1% sugar, has a ratio of 1 : 1.6 (3.4 : 5.45). Mother's milk, containing 2% protein, 4% fat, and 6.5% carbohydrates, has a ratio of 1 : 7.75. To substitute cow's milk for mother's, it must therefore be "modified."

=Calories.=—Another way of comparing various foods than by the nutritive ratio is by measuring their "fuel value" or energy-producing capacity. The amount of heat required to raise the temperature of one kilogram of water 1° C., or one pound 4° F., is called a calorie. By extensive feeding experiments the caloric value of the various nutrient groups has been estimated as follows:

Protein at 1820 calories per pound[9] Fats at 4040 calories per pound Carbohydrates at 1820 calories per pound

Measured by this rule the fuel value of:

Whole milk is 310 calories per pound

Skim milk is 160 calories per pound

Full cream 1885 calories per cheese is pound

Butter is 3410 calories per pound

Compared with other food, milk, although not suited to act as the sole food of adults, is one of the best and cheapest articles of diet, and should be much more extensively used.

The following table, compiled by specialists of the U. S. Department of Agriculture, shows the quantities of various foods needed to supply as much protein or energy as 1 quart of milk:

■■■

=Fallacy of Theoretical Valuation.=—While the contents of protein and the ratio between digestible protein and fats and carbohydrates on one hand, and the fuel or energy value on the other, have long been the only recognized measures for food values, they are admittedly quite inadequate and insufficient and although they are a great help when used with discrimination in making up food rations, they are often abused by persons who do not take their fallacies into consideration.

[Illustration:

Dr. E. V. McCollum]

"=Something Unknown.="—Recent investigations by Dr. F. G. Hopkins, of Cambridge, England, and Dr. E. V. McCollum, formerly of Wisconsin, now of the Johns Hopkins University, have proven conclusively that one food ingredient cannot always be substituted for another with impunity even though the most searching chemical analysis shows them both alike in contents and digestibility. There is "Something Unknown" in certain foods—"Vitamines" some call it—essential especially in promoting the growth of the young, which our present knowledge of chemistry cannot explain. In Bulletin No. 17 of the Wisconsin Experiment Station experiments with the feeding of rats are described which show how butter-fat could not be replaced in the ration by vegetable fats of apparently the same composition and digestibility without disastrous results, and similar conditions have been found in regard to other foodstuffs, proteins as well as fats. The yolk of eggs and butter-fat contain this unknown something which is absolutely essential for the growth of the child and which is missing in most substitutes, especially in lard and vegetable fats.

[Illustration:

The rat on the left got five per cent of cottonseed oil and the one on the right got instead one and a half per cent of butter-fat, otherwise their rations were alike. These results are typical for any ration made up of purified foodstuffs with butter-fat in them as compared with any fat of plant origin. The plant fats lack an unknown something without which growth cannot proceed.]

The above illustration is from the work of McCollum and Davis at the Wisconsin Experiment Station.

Realizing the fallacy of the old rules for making up rations for the feeding of farm animals, Professor Evvard of Iowa is trying the _reliability_ of the _instincts_ of animals as a guide to the proper selection of the most favorable combinations and proportions of food ingredients.[10]

We mention these experiments as a warning against placing too great reliance on the caloric theory or the relation of nutrients in making up food rations. We have yet much to learn and the good housewife trying to cook according to scientific rules will do well not to neglect the palatability of the food, but to watch the "instinct" which causes the child or the adult to reject or approve of, and enjoy, the food, which in most cases is a better guide than calories or protein contents, or the ration between the various groups of nutrients.

CARE OF MILK IN THE HOME

If received fresh and warm from the cow, milk should at once be strained through absorbent cotton or several thicknesses of cheese-cloth into wide-mouthed bottles or glass jars and placed in running water or ice water to cool as quickly as possible. If obtained from the milkman it may be left in the bottle in which it is received. The practice of delivering milk "loose," dipping it from the wagon, should not be permitted, and is fast being abolished. Public safety demands that it should be bottled on the farm or in the creamery or milk station under sanitary conditions.

=Keep the Milk Cool.=—If the milk when delivered at the house is not cold enough to keep sweet as long as desired, it should, we repeat, be placed in ice water or cold running water until thoroughly cooled. Even if the air is cold, in the ice box, for instance, the milk cannot be cooled quickly enough without water. After it has been cooled in water it may be put in the ice box. In most ice boxes the temperature is allowed to rise higher than is generally supposed, and it is better to keep the milk bottle next to the ice than in the food compartments.

[Illustration:

A clean ice box]

Milk and cream easily absorb flavors from the air and should not be kept in open vessels next to other food. Any housekeeper knows how quickly milk or cream will be tainted by standing in the same compartment with onions or muskmelons; if the bottle is

not covered, milk may also be contaminated by other less noticeable but more harmful vapors from nearby products. Let the milkman furnish you with some extra milk bottle caps, or cover your milk bottle with an inverted tumbler.

As has been shown in previous chapters, milk is a favorable soil for all sorts of germs and bacteria to grow in. It must therefore be kept from contamination with the utmost care, and everything that comes in contact with it must be scrupulously clean.

=Top-Milk.=—When the milk has been standing at rest three or four hours, the top-milk will be considerably richer than the rest. If such rich milk is wanted for any particular purpose it may be poured off, to be eaten with cereals, berries, etc. In twelve hours most of the cream will rise and may be skimmed off, although thirty-six or even forty-eight hours may be required to get all that can be obtained by setting. The half-skimmed milk left when the top-milk has been removed after 3 to 6 hours' setting will still contain 2% or more of butter-fat and is very good for drinking; even the skim milk from which the cream has been taken after 12 hours' setting is still an excellent beverage, provided it is sweet. Perfectly skimmed, almost entirely fatless, milk may be used in various ways in cooking, to make up for lack of protein in many other food products. But care must be taken that it is pure and sweet, or rather, its condition, sweet or sour, must be under the perfect control of the housekeeper. If a sample of milk will stand scalding or even boiling without curdling, it is usually fresh and in good condition for any use. On the other hand, if it curdles by scalding, it is beyond control and it may or may not make good sour milk, depending on the bacteria working in it.

MILK FOR INFANTS

[Illustration]

Comparing cow's milk with mother's milk, it will be seen that the latter contains less protein, about the same percentage of fat and more carbohydrates than the former. A comparison may be made from the following table of average composition in round figures:

■■■

as fresh milk. Every time the baby is fed the milk must be warmed by placing the bottle in a pan of water and heating to the right temperature.

Mrs. Rorer's Recipe

Where cow's milk, even when diluted, or partly modified as in the home fashion, disagrees with the infant, this mixture may be used with good results: heat two quarts of milk to 100° F. Add two Junket Tablets dissolved in a tablespoonful of cold water. When the milk is congealed and perfectly solid draw through it backward and forward an ordinary four-tined silver fork; this will separate the curd. Strain through two thicknesses of cheese-cloth, saving the whey as this is the part you are to use; add a pint of water, a half ounce of sugar of milk, three ounces of cream and four ounces of the white of egg. The whites may be dropped into a quart fruit jar, a pint of the whey added, the top screwed on and the jar thoroughly shaken until the whites are well mixed with the whey; then add them to the remaining quantity and stand at once in a very cold place. This will be given in quantities from two to three ounces in an ordinary nursing bottle.

RECIPES _of the Nathan Straus Laboratories_

Formula by Dr. A. R. Green for 1st to 4th week:—

¾ ounces of 16% Cream 3 ounces of Full Milk 19 ounces of Water 1½ ounces Milk Sugar

This mixture fills 8 bottles—each to contain 3 ounces. Feed 2½ hours apart.

Formula by Prof. A. Jacobi for 3d to 7th month:—

18 ounces of Full Milk 18 ounces of Barley Water 1 ounces of Cane Sugar 20 grains of Table Salt (less than ¼ teaspoonful)

This mixture fills 6 bottles—each to contain 6 ounces. Feed 3 hours apart.

Formula by Prof. R. G. Freeman for 1st to 3d month:—

1½ ounces of 16% Cream 3 ounces of Full Milk 13 ounces of Water ½ ounce Lime Water 1 ounce Milk-Sugar

This mixture fills 6 bottles—each to contain 3 ounces. Feed 3 hours apart.

Formula by Dr. A. F. Hess for 7th to 9th month:—

22½ ounces of Full Milk 7½ ounces of Oat or Barley Water 1½ ounces of Cane Sugar 30 grains of Table Salt (about ¼ teaspoonful)

This mixture fills 5 bottles—each to contain 6 ounces. Feed 3½ hours apart.

Formula by Prof. R. G. Freeman for 2d to 6th month:—

18 ounces of Full Milk 16½ ounces of Water 1½ ounces of Limewater 1½ ounces of Milk Sugar

This mixture fills 6 bottles—each to contain 6 ounces. Feed 3 hours apart.

After 9th month:—

Full pasteurized milk, 8 ounces every 4 hours.

When the modified milk can be obtained from a dairy laboratory where it is prepared with scientific care and accuracy, it is better to use it than to depend on home-made preparations, and in many cases a doctor's prescription may be necessary. Even if the modified cow's milk is prepared so as to contain apparently the same proportion of the various groups of nutrients as mother's milk, there may still be some essential difference. For instance, the protein in human milk consists mainly of albumin, while that of cow's milk is mostly casein. It is often a question whether the individual baby can digest the casein without trouble. A trifle of rennet ferment,—a fraction of a Junket Tablet,—added to the modified cow's milk just before feeding may be beneficial to overcome that defect. A little limewater also is healthful as it neutralizes any acid that may develop in the mixture. For the particular needs of the individual baby, a competent doctor should be asked to prescribe.

MILK FOR GROWING CHILDREN

[Illustration]

When the child is big enough to thrive on undiluted, unmodified cow's milk, it should not only be allowed, but urged, to continue on a diet in which this, the best of all foods, is the most essential part. An excellent form in which to feed milk to the growing child is junket. Eaten slowly with a spoon as a pudding, it is exposed to the action of digestion much better than milk swallowed by the glassful in a hurry and even if it is cold there is no danger of defective rennet action in the stomach because such action has already taken place.

Doctors still disagree as to the desirability of pasteurizing milk for young children (see "Pasteurization," Chapter I), some holding that the digestibility is affected by the process. The truth is probably that strong pasteurization at a temperature above 157° and holding the heated milk unnecessarily long at such high temperature do change the properties of the milk so as to make it harder to digest, but that the main difficulty is in the change of diet from raw to pasteurized milk or vice versa. Let the child get used to the change by making it gradual, diminishing the amount of one and increasing the amount of the other from day to day in a week, until the change is completed, and there will usually be little if any trouble. The secretions of digestive ferments in the stomach soon adapt themselves to the change in the food. The same holds good in case of other changes, as, for instance, from whole milk to more or less fatless milk, with additions of cereals or other partial substitutes;—it is always advisable to make any change in the child's diet gradual.

CHAPTER V

MILK COOKERY

Milk should also be used a great deal more than it is by grown persons, not only as a drink but in the daily cookery. In some homes milk in some form is a part of every menu and the meals are more delicious, attractive and nourishing than the ordinary milkless diet, and are also less expensive, as the milk takes the place of part of the meat. Dr. Graham Tusk of Cornell University, who represented the United States on the Interallied Council of Alimentation, says:

"No family of five should spend any money for meat until three quarts of milk have been purchased, and this should be done even though the price of milk should go to twenty cents a quart. Absolutely nothing in the food line will keep children so healthy as their daily supply of milk."

In cooking with milk it is well to remember:

1. That, although milk is a liquid, it contains a large amount of solid food and of exceedingly nourishing, palatable and easily digestible food, much more than many vegetables or fruits. While milk has 13% of solid matter, water-melon has only 2%, turnips 4%, beets 12%, etc. When substituting milk for water, you add _nourishment_ to the food and it is well to keep in mind the ingredients,—the amount of protein, fat, etc., added in the form of milk, which may take the place of other similar ingredients in the combination.

2. That if milk is even but slightly sour, or if some other acid is added to it,—in the form of fruit, for instance,—it is apt to curdle by scalding or boiling.

The limits of a single chapter do not allow many recipes to be given, but a few are furnished under each of the several kinds of milk dishes, and a clever domestic science pupil or the ordinary good housekeeper and cook can easily add to these recipes indefinitely, by following out the simple suggestions offered.

All measurements are level.

SOUPS

=Cream Soups.=—So-called cream soups may be made with or without the addition of meat stock. For example:

=Asparagus Soup=

3 cups veal or chicken broth 1 can asparagus ¼ cup butter ¼ cup flour 1 qt. scalded milk Salt and pepper

Reserve tips of asparagus. Add stalks to cold stock, boil fifteen minutes, rub through sieve, thicken with butter and flour cooked together, add milk, tips, salt and pepper. If fresh asparagus is used, cut one bunch in small pieces, boil in as little water as will cover, remove tough bits of stalk, add two cups stock and proceed as above.

=Cream of Celery Soup=

3 cups veal or chicken broth 3 cups celery cut in inch pieces 4 cups milk Yolks 2 eggs ½ cup cream Salt and pepper

Boil celery in broth till tender. Rub through sieve, add milk, bring to the boiling point and add egg yolks beaten and diluted with cream.

=Spinach Soup=

4 cups broth 2 qts. spinach 3 cups boiling water 2 cups milk ¼ cup butter ½ cup flour Salt and pepper

Wash the spinach and cook thirty minutes in boiling water to which ■ teaspoon soda has been added. Drain and chop fine. Add stock and butter and flour cooked together, milk and seasoning.

Cauliflower, mushrooms, lettuce, string beans, onions and other vegetables may be used for soups in the same way. _In all of these recipes milk may be substituted for the stock._ The soups will be more nourishing, many like them better, and they are more easily prepared.

If canned vegetables are used they may be added to the thickened milk, which should be made in the proportions of one quart of milk to two tablespoons butter or substitute and two tablespoons flour. One can of beans, peas, asparagus, or corn, may be added to three pints of thickened milk.

If fresh vegetables are used, they should be boiled in as little water as possible and this water added with the vegetables to the hot, thickened milk. The addition of one-half to one cup of cream to these soups improves their taste but is not necessary. If the cream is whipped and added just before serving, the appearance is also much improved. The vegetables may be pressed through a sieve or not, as preferred. If the soup is to be served in cups it is better to do this or chop the vegetables very fine, but if the soup is to be served in soup plates it looks attractive and is more substantial if the vegetables are cut in inch pieces and left in the soup.

All cooks are familiar with _cornlet soup_, _tomato_ _bisque_, and _oyster_ and _clam stews_, the foundation of which is also milk. Plenty of good recipes for them can be found in any standard cook book.

=Cereal Cream Soups.=—There is another class of soups used much in Europe but, unfortunately, little known here. They are very nourishing, easy of preparation, and delicious.

A few recipes will suffice to introduce the housewife to this class of soups and she can then easily add to the varieties herself. Her family will enjoy the new dishes for their good taste and their novelty. Croutons, crackers, zwieback, or toast may be served with any of them. They should always be prepared in a double boiler.

=Rice Soup=

1 qt. milk ■ cup rice 1 tablespoon butter 1 tablespoon sugar

Heat the milk in a double boiler, add the rice and cook two hours. Add sugar and butter. Sprinkle cinnamon on each plate of soup when serving.

=Sago Soup=

1 qt. milk 4 tablespoons sago 1 tablespoon butter 1 egg yolk 2 tablespoons sugar

Heat the milk in a double boiler, add sago and cook one-half hour. Care must be taken to stir the mixture often when the sago is first added or it will lump. Add butter and egg yolk beaten with sugar.

=Oatmeal Soup=

1 cup oat flakes 1 pint boiling water 2 tablespoons sugar 1 pint milk 1 tablespoon butter

Add oat flakes to water and boil one-half hour. Add milk and boil one-half hour, add sugar and butter.

=Farina or Cream of Wheat Soup=

3 pints milk ½ cup farina or cream of wheat 1 tablespoon butter 1 tablespoon sugar

Scald milk and add cereal slowly. Cook one hour and add butter and sugar and a sprinkling of nutmeg.

=Milk Chowders=

Chowders are also a very acceptable way of serving milk. For rich chowders the proportions used are: Two cups of milk or of milk and water, 1 cup of potatoes cut into small pieces and 1 pound of fish. For flavoring add an onion fried in two tablespoons of fat tried out from salt pork. While these proportions make a rich dish, it is possible to reduce the amount of fish greatly, to leave it out entirely, to use small portions of left-over fish or some salt codfish which has been freshened, or to substitute corn for it. Such dishes are palatable and of reasonably high nutritive value, providing the greater part of the liquid used is milk.

Similar, but less rich and thick, is:

=Milk Stew=

1 qt. of milk 1 cupful raw potatoes cut into small pieces 2 tablespoonfuls of butter or bacon fat 1 cupful of codfish cut into small pieces or just enough to flavor the stew

Soak the fish in lukewarm water until it is soft and the salt removed. Cook the potatoes in water until tender, drain them, add the milk and codfish, and bring to the boiling point; add the butter and salt to taste.

In place of the codfish, fresh fish, clams, oysters, or a little chipped beef may be used. Or the fish may be omitted and the soup made savory and palatable by adding a few drops of onion juice, or cheese or a vegetable cut into small pieces and cooked thoroughly.

MILK CEREALS

Most cereals are better cooked in milk than in water and those not familiar with this method have no idea of the many good dishes which they can thus easily provide for their families. Cereals so prepared make an especially good wholesome breakfast or supper for school children and the writer has never seen an adult, who, on a cold night, did not enjoy a dish of rice, or corn meal, boiled in milk and served with cream and sugar for supper. Milk cereals must always be cooked in a double boiler and the milk must be hot when the cereal is added.

Rice 1 cup to 3 cups milk, boil 2 hours Cornmeal 1 cup to 4 cups milk, boil 1 to 2 hours Fine Hominy 1 cup to 4 cups milk, boil 1 hour Cream of Wheat 1 cup to 4 cups milk, boil 1 hour Farina 1 cup to 4 cups milk, boil 1 hour

=Cream of Wheat or Farina Pudding= is also delicious. It is prepared in the same way, but ¾ cup of cereal only is added to 1 quart hot milk. Just before serving, a teaspoonful of vanilla is added, and two beaten eggs are folded in. It is eaten with cream, or milk, and sugar, or with maple syrup.

LUNCHEON AND SUPPER DISHES

Dishes prepared principally of milk, with the addition of either eggs, cheese, meat, or vegetables are particularly adapted for luncheon or supper use. Here again a few standard recipes are given which can be varied to make any desired number of good, wholesome and delicious dishes.

=Creamed Dishes.=—The same sauce may be used to cream _cold chicken_, _lamb_, _veal_, _chipped beef_, and cold boiled or baked _fish_, canned _salmon_, _lobster_ or _shrimps_, according to the following recipe:

=Creamed Chicken=

2 cups cold cooked chicken cut into dice 3 tablespoons butter 3 tablespoons flour 1½ cups milk Salt and pepper

Melt butter and add the flour and milk. Bring to the boiling point and add diced chicken. Season with salt and pepper.

Many grate a small onion into the sauce before adding the chicken. The writer does not favor indiscriminate use of onion as it tends to make all dishes taste alike. It seems better to use sometimes a little celery or celery salt, sometimes an onion, and again frequently no flavor but the chicken or meat or fish. One's cooking is thus more distinctive and varied.

If the creamed mixture is turned into a baking dish, covered with buttered bread or cracker crumbs and browned in the oven, the result is even more pleasing.

Such a sauce flavored with cheese makes a good and very nutritious gravy to pour over cauliflower and cabbage or to serve with boiled rice or hominy or poured over toast.

CREAMED VEGETABLES

In creaming vegetables the proportion is usually 1 cup of sauce to 2 cups of vegetables. _Potatoes_, _asparagus_, _cauliflower_, _boiled onions_, _beans_, and _carrots_, _beets_ or _peas_ are all delicious served in this way.

=Eggs and Asparagus=

Cream asparagus. Arrange in a baking dish, alternate layers of the asparagus and slices of hard boiled eggs. Cover with buttered crumbs and bake till crumbs are a delicate brown.

=Souffles.=—Souffles are always delightful, and while many consider them difficult to make they are really very simple and if made correctly are always to be depended upon. They should, however, be eaten at once when baked.

Salmon, _chicken_, _lamb_, _veal_, _ham_ and _cheese_, and also many vegetables such as _asparagus_, _cauliflower_ and _peas_ may be prepared in this way. Elaborate recipes are often given, but the following is entirely sufficient and always satisfactory:

2 cups chopped meat or vegetables cut fine 2 cups thick white sauce Yolks of 2 eggs Whites of 2 eggs

To the meat or vegetables add white sauce (2 tablespoons butter and 3 tablespoons flour to 1 cup milk) and beaten yolks. Cool and add whites beaten stiff. Bake 30 minutes in moderate oven. This makes a dish large enough to serve four or five persons.

A similar dish, Cheese Fondu, is also good, and can stand longer than a souffle before serving.

=Cheese Fondu=

2 cups milk 2 cups minced cheese 1 cup bread crumbs 2 eggs beaten

Bake in a hot oven for twenty minutes.

Variations of this dish are made by substituting one cup minced ham for one cup of the cheese, or by using two cups of ham and omitting the cheese altogether.

MILK TOAST

A very good way to serve milk toast is to toast bread thoroughly and to pour hot milk over it at the time of serving. In serving milk toast in this way all the dishes should be kept very hot. A heavy earthenware pitcher may be used for serving the hot milk, as it retains heat for a long time.

EGGS POACHED IN MILK

Eggs are much better poached in milk than in water. If served on toast the hot milk may be poured on the egg if a soft toast is desired. If not, dip the eggs out of the milk with a perforated spoon and lay on the toast in the usual way, adding salt and butter.

CHEESE DISHES AS MEAT SUBSTITUTES

Meat is wholesome and relished by most persons, yet it is not essential to a well-balanced meal, and there are many housekeepers who, for one reason or another, are interested in lessening the amount of meat which they provide or to substitute some other

foods for it.

Cheese naturally suggests itself as a substitute for meat, since it is rich in the same kinds of nutrients which meat supplies, is a staple food with which everyone is familiar, and is one which can be used in a great variety of ways. In substituting cheese for meat, pains should be taken to serve dishes which are relished by members of the family. A number of recipes for dishes which are made with cheese follow:

=Cheese Soup=

1 qt. milk 1 onion grated 1 blade mace 2 tablespoons butter 2 tablespoons flour ½ c. grated cheese 2 egg yolks 1 teaspoon salt ¼ teaspoon white pepper

Scald milk, onion, mace and pepper pod. Melt butter in saucepan, blend flour with melted butter. Strain milk and seasonings and add gradually to flour mixture, stirring all the time. Return to double boiler to cook. When creamy, add the cheese, salt and pepper, stirring until cheese is melted. Then pour over well-beaten egg yolks, stirring all the time. Whip until frothing and serve.

=Delmonico Potatoes=

Arrange creamed potatoes and grated cheese in alternate layers. Cover with buttered crumbs and bake till crumbs are brown.

=Stuffed Potatoes with Cheese=

Split hot baked potatoes lengthwise and remove contents without injuring skin of potato. Put potato through ricer or mash, add salt and pepper to taste and enough hot milk to make of proper consistency. Beat until light, refill the skin, piling up lightly. Sprinkle thickly with grated cheese and reheat in oven until cheese is melted and a delicate brown.

=Macaroni with Cheese=

1 cup macaroni 2 qts. boiling salted water 2 cups white sauce 1 cup grated cheese 1 cup buttered bread or cracker crumbs

Break macaroni into one-inch pieces. Cook in boiling water until tender. (If macaroni is put in a wire basket in kettle, it will not stick to the kettle.) Drain and run cold water through it.

Make sauce:

2 tablespoons butter 2 tablespoons flour 1 teaspoon salt 2 cups milk

Add cheese and macaroni. Cover with crumbs and bake until crumbs are brown.

=Rice Baked with Cheese=

1 cup rice 2 qts. boiling salted water ½ lb. grated cheese Milk Buttered crumbs (bread or cracker)

Add rice to boiling water. When tender drain, cover bottom of buttered baking dish, sprinkle with grated cheese and a little paprika. Add alternate layers of rice and cheese until dish is full. Add milk nearly to fill dish. Cover with crumbs and bake until milk is absorbed and crumbs are brown.

=Cheese Souffle with Bread Crumbs=

1 cup scalded milk 1 cup soft, stale bread crumbs ¼ lb. mild cheese, cut in small pieces 1 tablespoon butter ¼ teaspoon salt 2 egg yolks 2 egg whites

Mix milk, bread crumbs, cheese, melted butter and salt. Add yolks of eggs beaten until lemon colored. Cut and fold in whites of eggs beaten until stiff. Pour into a buttered baking dish and bake twenty minutes in a moderate oven.

=Cheese Souffle=

2 tablespoons butter 3 tablespoons flour ½ cup scalded milk ½ teaspoon salt Few grains cayenne ¼ cup grated cheese Yolks of 3 eggs Whites of 3 eggs

Melt the butter in a saucepan, add the flour and mix well; add scalded milk gradually and seasonings; cook two minutes. Remove pan to back of stove and add cheese and well-beaten yolks of eggs. Set pan where mixture will cool. When cold, add the whites of eggs beaten until stiff and dry. Turn into a buttered baking dish and bake twenty minutes in a slow oven. Serve the moment it comes from the oven.

=English Monkey=

1 cup bread crumbs 2 cups milk 1 cup grated cheese ½ teaspoon salt ¼ teaspoon white pepper or paprika 1 egg 1 tablespoon melted butter

Scald milk in double boiler and add bread crumbs to it. Then add grated cheese, melted butter and seasonings. Cook in double boiler until cheese is melted; add the slightly-beaten egg gradually. Cook five minutes and serve on dry toast.

=Cheese Omelette No. 1=

4 eggs ½ teaspoon salt Few grains pepper 4 tablespoons hot water 1 tablespoons butter 1 cup grated cheese

Beat yolks of eggs thoroughly; add salt, pepper and hot water. Beat whites till stiff and dry; add cheese and fold into first mixture. Melt butter in pan, turn in mixture and cook slowly. When well raised and a delicate brown underneath, place pan in hot oven to cook top. Fold and turn on hot platter.

=Cheese Omelette No. 2=

Make as above, omitting cheese. Make two cups of hot, white sauce; add 1 cup grated cheese, melt and pour around the omelette.

=Baked Eggs with Cheese=

4 eggs 1 cup grated cheese 1 cup soft bread crumbs ¼ teaspoon salt Few grains cayenne 2 cups white sauce

Break the eggs into a buttered baking dish and cook in hot oven until they begin to turn white around the edges. Then cover eggs with the white sauce and over this put the mixture of crumbs, cheese and seasonings. Brown in very hot oven, so eggs will not be overcooked by time cheese is brown. If preferred, or for variety, the cheese may be added to the white sauce and only the seasoned crumbs put on the top.

=Boston Roast=

1 can kidney beans or same amount of cooked beans Salt ½ lb. grated cheese Bread crumbs

Mash beans or put them through a meat grinder. Add the cheese and sufficient bread crumbs to make the mixture stiff enough to be formed into a roll. Place in buttered baking pan and bake in moderate oven. Baste frequently with one-half cup hot water, in which one tablespoon butter is melted. Serve the roast with tomato sauce. If desired, a few drops of onion juice or a little finely chopped onion may be added to flavor this dish.

=Camouflaged Cabbage=

Remove the heart from a small cabbage, cut or chop the remainder into half inch pieces, boil in salted water exactly twenty minutes and drain. For one pint of this cooked cabbage make a sauce of:

2 tablespoons butter 2 tablespoons flour ½ cup milk ½ cup cheese

When thoroughly blended add the cabbage; cover with buttered crumbs and bake twenty minutes. The result is a good dish for supper or luncheon and it is well named.

CHEESE SALADS

=Cheese and Pimento Salad=

Stuff canned pimentos with cream cheese, cut into slices, place on lettuce leaves and serve with mayonnaise dressing.

=Cheese and Celery Salad=

Select celery stalks with deep grooves in them; wash and dry on clean towel. Mix a small cream cheese with a bit of salt, and ¼ cup finely chopped nuts (pecans are best). Fill grooves in celery stalk with the cheese mixture and chill. When ready to serve cut stalks into small pieces with sharp knife. Serve on lettuce leaves with French dressing.

For a pleasant addition to fruit salad, fill tender celery stalks with roquefort cheese, and lay one or two on each plate of salad.

=Pepper and Cheese Salad=

Remove top and seeds from a sweet green pepper. Scald it with boiling water, letting it stand in water about ten minutes. Mix soft cream cheese with chopped nuts, or with tiny cubes of cooked beets and fill pepper with this mixture; chill well, cut in thin slices with sharp knife and serve on bed of head lettuce with French dressing.

Apples can also be used (with cheese and nuts) by removing core without breaking the apple.

COTTAGE CHEESE (See also under the chapter on Cheese)

All that has been said of cheese as a valuable food and as a substitute for meat, applies equally to cottage cheese and it is so easily prepared, inexpensive and generally relished that it should be used much more freely than it is.

The following recipes are only a few of the many that might be given, but the careful cook should evolve other combinations equally attractive.

=Cottage Cheese by Government Method=

(From Food Administration Bulletin)

Unit, 1 gallon. For lesser amounts, measurements to be divided accordingly.

Take 1 gallon of sweet skim milk; add ¾ cup of clean, sour milk and stir as it is put in. Raise the temperature in hot water to 75 degrees Fahrenheit, using a dairy thermometer. Remove from heat and place where it is to remain until set. Add ■ of a junket tablet thoroughly dissolved in a tablespoon of cold water; stir while adding. Cover with cloth and leave for 12 to 16 hours in even temperature, about 75 degrees Fahrenheit. At end of this period there should be a slight whey on the top and when poured out the curd should cleave sharply. Drain through cotton cloth, not cheese-cloth. When whey has been drained out, work in 1 or 2 teaspoons of salt to the cheese, according to taste; 1½ to 2 pounds of cheese should be obtained from a gallon of milk.

For table use it is advisable to work in 1 or 2 tablespoons of cream to the pound. For use in cooking, this is not necessary.

One may also make cottage cheese of freshly soured milk by simply heating it in a double boiler till whey forms, letting it stand an hour and then turning it into a cheese-cloth bag to drain. To the dry curd formed add sweet or sour cream and salt to taste. When made in this way care must be taken that the milk is freshly soured—if it is old it will have a bitter taste and the cheese will not be good.

=Cottage Cheese Sandwiches=

Thin slices of rye, brown or white bread, buttered, with fillings of cottage cheese in combination with jelly, marmalade, pimentoes, lettuce or mayonnaise are all good.

=Cottage Cheese Club Sandwiches=

Toast slices of bread, cut diamond shape and spread with butter and cottage cheese or cottage cheese alone and put together with any one of the following combinations:

Tomato, lettuce and mayonnaise dressing.

Thin slices of ham spread with mustard and lettuce.

Sliced, tart apple, chopped nuts and drops of French dressing.

Sliced orange and mayonnaise.

Sliced Spanish onion, a hot fried egg sprinkled with Worcestershire sauce.

Thin slices of tomato, bacon, chicken, lettuce and mayonnaise dressing.

=Cottage Cheese Salad Dressing=

½ cup cottage cheese 1 tablespoon vinegar ½ teaspoon sugar ¼ teaspoon salt 1 cup heavy cream (either sweet or sour) whipped stiff.

Mix in order given. A chopped hard boiled egg improves it.

A similar salad dressing, although containing no cottage cheese, may be given here also.

=Sour Cream Salad Dressing=

1 cup sour cream—whipped 1 tablespoon vinegar 1 tablespoon olive oil ¼ teaspoon salt (1 teaspoon sugar, if desired) 2 hard boiled egg yolks finely chopped

Mix in order given.

Either of these is particularly good with green vegetables.

For a fruit salad the eggs should be omitted and double the amount of sugar used.

=Cottage Cheese Salad=

Lettuce, sliced cucumber or green, sweet peppers, cottage cheese formed in small balls or slices, mayonnaise or French dressing.

=Cottage Cheese Pie=

1 cup cottage cheese ■ cup sugar ■ cup milk 2 egg yolks, beaten 1 tablespoon melted butter Salt ¼ teaspoon vanilla

Mix the ingredients in the order given. Bake the pie in one crust. Cool it slightly and cover it with meringue made by adding 2 tablespoons of sugar and ½ teaspoon of vanilla to the beaten white of 2 eggs and brown it in a slow oven.

=Devonshire Dainty=

Serve on individual plates ½ cup cottage cheese to which has been added 2 tablespoonfuls whipped cream (sweet or sour). Over this pour ½ cup currant jam.

Pass saltines or other dry, unsweetened crackers.

MILK BREADS AND BISCUITS

=Parker House Rolls=

2 cups scalded milk (skim) 3 tablespoons butter 1 teaspoon salt 1 yeast cake dissolved in ¼ cup lukewarm water

Dissolve yeast in water, melt butter, combine all ingredients except flour. Add 3 cups flour gradually, beating vigorously. Let rise till light; cut down and knead in 2½ cups flour. Cover and allow to rise until three times original bulk. Roll ½ inch thick. Cut, spread half with butter and fold over. Put in buttered tins to rise, placing 1 inch apart. Bake when light in a hot oven 15 to 20 minutes.

=Popovers=

1 cup flour ¼ teaspoon salt 2 eggs ½ teaspoon melted butter 1 cup milk

Beat eggs thoroughly. Add gradually, while beating, the milk and flour, to which salt has been added. Add butter and beat two minutes with Dover egg beater. Put a half teaspoon of butter in hissing hot iron gem pans. Fill half with batter and bake thirty minutes in a hot oven. Serve immediately.

=Boston Nut Bread=

½ cup molasses 1 teaspoon soda 2 cups sour milk 2 cups graham flour 1 teaspoon salt ½ cup sugar 1 cup chopped nuts 1½ cups white flour

Mix and sift all the dry ingredients. Add molasses to the milk and combine this gradually with the dry materials. Add the nuts. Half fill baking powder cans, with oiled cover, and let stand one-half hour. Bake three-quarters of an hour in moderate oven.

=Sour Milk Biscuit=

1 qt. flour 1 teaspoon soda 1 teaspoon salt 1 teaspoon sugar 2 tablespoons butter Sour milk to moisten (about 1½ cups)

Sift dry ingredients together, cut in butter with knife, add milk to make a stiff dough. Roll out thin and bake in hot oven. Serve with honey or maple syrup.

=Gingerbread=

4 tablespoons butter ½ cup sugar 1 egg ½ cup molasses 2 teaspoons cocoa ½ cup sour milk 1¾ cups flour ¾ teaspoon soda 1 teaspoon ginger 1 teaspoon cinnamon ¼ teaspoon salt 1 teaspoon allspice

Sift flour and spices, salt and soda together. Mix other ingredients in the order given and combine mixtures. Bake in moderate oven 30 minutes.

=Sour Milk Waffles=

1 egg 1 cup sour milk 1 cup flour 1 tablespoon butter 1 teaspoon soda ½ teaspoon salt

Beat egg thoroughly, add sour milk, flour and salt. Dissolve soda in ½ tablespoon cold water. Add to mixture. Beat thoroughly. Cook on oiled, hot waffle iron and serve hot with maple syrup.

=Sweet Milk Waffles=

2 cups flour 3 teaspoons baking powder ½ teaspoon salt 1¼ cups milk Yolks 2 eggs Whites 2 eggs 2 tablespoons butter

Mix and sift dry ingredients, add milk, beaten yolks, butter and egg whites beaten stiff.

=Buttermilk Griddle Cakes=

2 cups buttermilk 2 cups flour 1 teaspoon soda 1 egg beaten

Mix in order given.

=Sweet Milk Griddle Cakes=

1 egg beaten 2 cups milk 3 cups flour sifted with 3 teaspoons baking powder and ½ teaspoon salt 2 tablespoons melted butter

Mix in order given.

=Boston Brown Bread=

1 cup whole wheat flour 2 cups graham flour 1 teaspoon soda 1 teaspoon salt 2 cups sour milk ½ cup molasses

Mix dry ingredients thoroughly. Mix the sour milk and molasses. Stir in dry ingredients, beating thoroughly. Turn into well buttered pound baking powder cans. Cover tightly and steam three hours. Take from can and slice, ½ cup raisins or nuts can be added to the dough mixture, if desired.

DESSERTS

For desserts the number of custards, creams and puddings made with milk is legion, and they are so well known and can be so easily varied that only a few stock recipes need be given.

=Boiled Custard=

2 cups scalded milk Yolks 2 eggs ¼ cup sugar ■ teaspoon salt ½ teaspoon vanilla

Beat eggs slightly, add sugar and salt; stir constantly while adding gradually hot milk. Cook in double boiler, continue stirring until mixture thickens and a coating is formed on the spoon; strain immediately, chill and flavor. If cooked too long the custard will curdle. Should this happen, by using a Dover egg beater it may be restored to a smooth consistency, but custard will not be as thick. Eggs should be beaten slightly for custard that it may be of smooth, thick consistency. To prevent scum from forming, cover with a perforated tin or sprinkle with granulated sugar when cooling.

=Blanc Mange or Cornstarch Pudding=

1 qt. milk ½ cup cornstarch Pinch of salt 3 eggs ½ cup sugar

Heat milk to boiling, add cornstarch dissolved in a little cold milk and a pinch of salt. Boil five minutes, add yolks of eggs beaten with sugar. Boil 2 minutes longer, remove from fire and beat in the whipped whites of eggs. Flavor with vanilla or lemon. Serve cold with cream and sugar or canned peaches or pears.

This is used also as a filling for cream pie, using the beaten whites of eggs, sweetened for a meringue and browning slightly in oven. Bake the crust before filling with the cream.

=Baked Custard=

4 cups scalded milk 4 eggs ½ cup sugar ¼ teaspoon salt Few gratings nutmeg

Beat eggs slightly, add sugar and salt, pour on slowly scalded milk, strain in buttered mold, set in pan of hot water. Sprinkle with nutmeg and bake in slow oven until firm, which may be readily determined by running a silver knife through custard. If knife comes out clean, custard is done. During baking care must be taken that water surrounding mold does not reach boiling point or custard will whey. Always bear in mind that eggs and milk combination must be cooked at a low temperature. For cup custards allow three eggs to four cups milk; for large molded custard four or five eggs; if fewer eggs are used, custard is liable to crack when turned on a serving dish.

=Baked Apple, Southern Style=

[Illustration]

6 choice apples ½ cup sugar 1 qt. milk Salt 4 eggs ■ cup sugar 1 teaspoon vanilla

Pare and core apples that are not too sour to hold their shape when baked. Put in a pudding dish, sprinkle the half cupful of sugar over and around them, also filling place where the core was taken out. Put in oven and bake. Remove from oven and pour around them the milk mixture made thus: Beat the eggs well, add sugar and beat again, add milk, salt and vanilla. Bake slowly until a knife-blade will come out clean after insertion in the custard. Serve hot or cold, with or without whipped cream. This is an especially good dessert for children.

=Coffee Custard=

2 cups milk 1 cup strong coffee 3 eggs ¼ cup sugar ■ teaspoon salt ¼ teaspoon vanilla

Beat eggs slightly; add sugar, salt, vanilla, milk and coffee. Strain into buttered individual molds, set in pan of hot water and bake until firm.

=Caramel Custard=

4 cups scalded milk 5 eggs ½ teaspoon salt 1 teaspoon vanilla ½ cup sugar

Put sugar in omelette pan, stirring constantly over hot part of range until melted to a syrup of light brown color. Add gradually to milk, being careful that milk does not bubble up and go over, as is liable on account of high temperature of sugar. As soon as sugar is melted in milk, add mixture gradually to eggs slightly beaten, add salt and flavoring, then strain in buttered mold. Bake as custard. Chill and serve with caramel sauce.

=Rice Pudding=

1 qt. milk ■ cup rice ½ teaspoon salt ■ teaspoon ground nutmeg, or cinnamon, or grated rind of ¼ of a lemon

Wash the rice thoroughly, mix the ingredients and bake three hours or more in a very slow oven, stirring occasionally at first.

=Tapioca Custard=

Add to the list of ingredients for boiled custard ¼ cup of pearl tapioca. Soak the tapioca in water for an hour or two, drain it, and cook in the milk until it is transparent. Proceed as for boiled custard.

GENERAL RECIPE FOR CEREAL-MILK PUDDINGS

Bread and rice puddings, made with milk and eggs, are familiar to all cooks. Made without eggs, the following will be found suggestive:

For a quart of milk allow ■ of a cup of any coarse cereal (rice, cornmeal, cracked wheat, oatmeal or barley); add ■ of a cup of brown, white or maple sugar, syrup, honey or molasses; ½ teaspoon salt; ■ teaspoon spice. The flavoring may be omitted when honey or molasses is used.

The above recipe makes quite a large pudding. It is often convenient to make a smaller one, and enough for a child's dinner can be made in the double boiler, allowing two level or one rounding tablespoon of cereal to a cup of salted and flavored milk. Cook an hour and sweeten slightly.

These puddings, if made thin, may be poured over stewed prunes or other cooked fruits, and are a good and economical substitute for the cream or soft custard usually used for that purpose.

A very old recipe for a baked corn pudding has recently been given to the author.

=Indian Meal Custard=

1 pt. sweet milk, when hot add slowly ½ cup cornmeal Pinch salt ½ teaspoon each cinnamon and ginger Sugar to taste 1 tablespoon molasses Boil 5 minutes, and add 2 beaten eggs 1 pt. milk Bake about one-half hour or till set.

=Milk and Fruit Mold[11]=

[Illustration:

Milk and fruit mold]

3½ cups hot milk, ½ cup cold milk, 5 tablespoons granulated sugar 10 tablespoons cornstarch 2 beaten egg whites 1 teaspoon almond extract, ½ teaspoon salt Candied cherries, cut into small pieces

Heat milk in double boiler. Mix cornstarch with cold milk, stir it into the hot milk, add salt and sugar and cook, stirring occasionally, for 10 minutes. Remove from fire, fold in the beaten whites and add the flavoring. Rinse mold in cold water, drain, pour in part of the cooked mixture, add a layer of cherries and continue until mold is filled. Set on ice to chill. May be served in tall glasses, as illustrated, or unmolded on a flat serving platter.

=Caramel Rice[11]=

6 cups milk 1 cup rice 1¼ cups granulated sugar 1 teaspoon salt 2 slightly beaten eggs Grated rind of half an orange

Cook rice, salt, the quarter cup of sugar and milk together in a double boiler until rice is tender. Remove from fire, add grated rind and beaten eggs and mix well.

Put the cup of sugar in a small saucepan over the fire and stir constantly until it is a golden brown liquid. Have a mold heating, and when very hot pour the liquid in it, turning the mold so that all parts are coated. Turn the rice into the mold and set it in a pan of water in a hot oven for 20 minutes, having the mold covered the entire time.

Remove from oven, let stand until cold, unmold and serve with the caramel sauce that is in the mold.

=Milk Cream=[11]

1½ cups hot milk ½ cup cold milk ■ cup granulated sugar 3 eggs ½ ounce granulated gelatine 1 teaspoon vanilla Pinch of salt

Soak gelatine in the cold milk for 10 minutes. Heat balance of milk in a double boiler, add salt, sugar and beaten yolks, stirring constantly. Cook until mixture coats the spoon, remove from fire, add soaked gelatine and stir until dissolved. Then set aside to cool and when beginning to thicken add flavoring and mix in lightly the stiffly beaten whites.

Rinse a mold in cold water, drain, pour in mixture and set in a cold place until firm. Unmold and serve plain or with thin cream.

[Illustration:

Milk cream]

=Plain Junket=

Heat a quart of milk until lukewarm, not to exceed 100° F. Remove from fire; sweeten and flavor to taste, using vanilla or any other desired flavor. Dissolve one Junket Tablet in cold water and stir the solution quickly into the lukewarm milk. Pour immediately into individual serving dishes, sherbet glasses, bowls or the like, and let stand warm until thickened. When “set” remove to ice box or other cool place without stirring and let stand until serving time. Serve with or without whipped cream, a sprinkle of nutmeg, or a few strawberries on the top, etc.

[Illustration:

Plain junket]

=Chocolate Junket=

Sweeten a quart of milk with half a cup of sugar. Melt one square of chocolate or two tablespoonfuls of cocoa, add half a cup of the milk and boil one minute. Remove from fire and add the remainder of the milk, which must not be boiled, and a teaspoonful of vanilla. Probably the mixture will be lukewarm, if not, warm until it is. Stir in dissolved Junket Tablet, pour at once into serving dishes and leave undisturbed until set. Chill and serve. If whipped cream sweetened and flavored with vanilla is heaped upon the Chocolate Junket when serving, a most attractive dessert is obtained, and Chocolate Junket frozen makes a delicious ice cream.

=Coffee Junket=

One-half cup very strong coffee, ½ cup sugar, added to 1¾ pints of heated milk. Dissolve. Add your Junket Tablet and finish as ordinary Junket. Serve with cream.

An endless variety of Junkets can be made by varying flavor and color, by adding fruit or preserves, etc., and in the sick room various medicines or stimulants, peptone, wine, etc., may conveniently be administered as an ingredient in the pudding.

=“Prepared Junket”=

Prepared Junket in which all the ingredients are found except the milk is on the market in the form of a powder called “Nesnah.” It is put up in various flavors and is easily and quickly made when milk is at disposal.

Heat 1 qt. milk lukewarm, remove from fire, add one package of the prepared Junket and dissolve quickly and thoroughly by vigorous stirring for ½ minute only. Pour immediately into individual serving dishes and let stand in warm room until thoroughly set. Place in ice box until serving time. Serve with or without plain or whipped cream.

MILK BEVERAGES

=Whey=

1 qt. fresh milk 1 Junket Tablet 1 tablespoon cold water

Heat the milk until lukewarm and add the tablet dissolved in the cold water. Allow it to set in a warm room. Then break up the curd gently and strain it through two thicknesses of cheese-cloth, being careful to remove all the casein. Cool at once and serve cold,

without or with sweetening, and flavor as desired.

=Lemon Whey=

1 qt. hot milk 3 tablespoons sugar ½ cup lemon juice

Heat the milk in a double boiler and add the lemon juice. Cook without stirring until the whey separates. Strain through cheese-cloth and add the sugar. Serve hot or cold, garnished with small slices of lemon.

=Cinnamon and Milk=

1 qt. new milk Stick cinnamon Sugar

Boil milk with sufficient cinnamon to flavor as desired. Sweeten and serve warm or cold.

=Rice Milk=

1 ounce rice 1 pint milk 1 saltspoon salt 1 teaspoon sugar

Soak the rice twelve hours. Add the scalded milk, salt and sugar. Stir well and cook one hour; then rub through a fine sieve. Thin with more hot milk and serve.

=Kumyss= (see also Chapter II)

■ cake Fleischmann's yeast 1¼ tablespoons sugar 1 tablespoon water 1 quart milk

Make a thin syrup of the sugar and water and cook one minute. Soften the yeast in two tablespoons of lukewarm milk. Heat the milk until lukewarm, add other ingredients and shake. Put in stone, sterile bottles, place in an upright position for twelve hours, at 70° (kitchen heat); then turn on side and leave at a temperature of 50° (lower part of ice box). Ready for use after the first twenty-four hours; often kept several days, but the longer it is kept the less palatable it is. It should look like thick, foamy cream.

=Egg Milk Shake=

1 egg 1 cup milk Sugar Vanilla

Break the egg into a large glass and beat well. Add sugar and a couple of drops of vanilla or a dust of nutmeg and beat again. Fill up glass with rich milk. This makes a very nourishing drink.

=Buttermilk Shake=

1 cup buttermilk 1 egg Sugar Few drops lemon extract Salt

Break egg into bowl, beat thoroughly with egg beater, add sugar, flavoring, a tiny pinch of salt and buttermilk. Beat again till light and foamy. Turn into glass.

=Buttermilk Lemonade=

A variation may be made from ordinary buttermilk by the addition of lemon juice and sugar. "Buttermilk lemonade" usually requires the juice of three lemons to one quart of buttermilk. The quantity of lemon and sugar, however, should be varied to suit the taste of the individual. The beverage is delightful and is especially refreshing on a hot summer day.

One may also use the juice of two oranges and one lemon to one quart of buttermilk, instead of the lemons alone.

Many people like the clear buttermilk slightly sweetened with a few grains of salt added.

=Chocolate=

1½ squares chocolate 4 tablespoons sugar Few grains salt 1 cup boiling water 3 cups milk ½ teaspoon vanilla

Scald milk. Melt chocolate in small saucepan and gradually add boiling water. When smooth add to scalded milk, sweeten and add salt and vanilla. Mill with Dover egg beater, and serve, putting a large teaspoon of whipped cream on each cup.

=Cocoa=

¼ cup cocoa ¼ cup sugar Few grains salt 1 cup water 3 cups milk ½ teaspoon vanilla

Mix cocoa and sugar, add water and stir into milk already heated in double boiler. Cook 15 minutes, add vanilla and salt. Serve with whipped cream. A famous cook known to the writer adds 1 teaspoon cornstarch dissolved in 1 tablespoon cold water to the cocoa when nearly ready for the table. It adds to the apparent richness of the beverage.

MISCELLANEOUS SUGGESTIONS

1. A tablespoonful of milk put in the pan before frying eggs will keep them tender.

2. Covering cold chicken or other meat with buttermilk will keep it for twenty-four hours or more, without affecting the meat except to make it more tender.

3. Custards and ice cream kept too long in warm weather may cause ptomaine poisoning.

4. Keep milk covered to shut out flavors from other food.

5. Milk warm from the cow should not be kept in a closed receptacle.

6. Danish cooks soak a piece of veal in skim milk overnight before roasting it, to improve the flavor.

7. Sliced ham covered with milk and baked in a moderate oven for an hour has delicate flavor and is always tender.

THE THERMOMETER

[Illustration:

Dairy and household thermometers]

In the United States and Canada as well as in England _Fahrenheit's_ thermometer is generally used according to which water freezes at 32° and boils at 212° at ordinary air pressure, leaving 180 degrees between the freezing and the boiling point. In some countries in Europe Réaumur's thermometer is used with 0° for the freezing point and 80° for boiling. In France and for scientific work in all countries, however, the Celsius or Centigrade system is employed for measuring heat and cold, having 0° for freezing and 100° for boiling. As there are 180° Fahrenheit, 80° Réaumur and 100° Centigrade between freezing and boiling, the divisions are therefore as 9° F. to 4° R. and 5° C.

To change from degrees of F. above the freezing point to the other systems deduct 32, divide the remainder by 9 and multiply by 4 or by 5 respectively. To change from C. to F. divide by 5, multiply by 9 and add 32, etc. As the metric system is gradually being introduced everywhere instead of the old systems for weights and measures, so also is the Centigrade thermometer being substituted for the others and in cookery it may soon be used exclusively.

WEIGHTS AND MEASURES

1 pound = 16 ounces = 453.6 grams 1 ounce = 16 drams = 28.35 grams 1 kilogram = 1000 grams = 2.2 pounds 1 gram = 15.43 grains = .035 ounces

1 gallon = 4 quarts = 3.785 liters 1 quart = 2 pints =.9464 liters 1 pint = 16 fluid ounces = .4731 liters 1 fluid ounce = 8 drams = 29.57 c.c. 1 liter = 1000 cubic centimeters = 1.0567 quarts

1 mile = 5280 feet = 1.6 kilometer 1 foot = 12 inches = .3048 meter 1 kilometer = 1000 meters = .6214 mile 1 meter = 100 centimeters = 39.37 inches

1 acre = 43,560 sq. ft. = .4047 hectare 1 sq. ft. = 144 sq. inches = 9.29 sq. decimeters 1 hectare = 10,000 sq. meters = 2.471 acres 1 square meter = 100 sq. decimeters = 10.764 sq. ft. 1 bushel = 4 pecks = .3552 hectoliter 1 hectoliter = 2.8377 bushels

1 U. S. gallon = 128 ounces = 231 cb. inches 1 Imperial gallon (English and Canadian) = 160 ounces = 277 cb. in. 6 U. S. gallons = 5 Imperial gallons

1 gallon of water weighs 8.34 pounds 1 gallon of milk weighs 8.6 pounds A 40 quart can of milk = 86 pounds

Approximate Household Weights and Measures

4 saltspoonfuls = 1 teaspoonful 3 flat teaspoonfuls = 1 heaping teaspoonful 1 heaping tablespoonful of granulated sugar = nearly 1 ounce 1 rounded tablespoonful of butter = 1 ounce 2 ordinary cups of granulated sugar = 1 pound 3 ordinary cups of wheat flour = 1 pound 1 pound of granulated sugar = 1 pint

4 flat teaspoonfuls of liquid = 1 flat tablespoonful = ½ fluid ounce 4 large tablespoonfuls = 1 ordinary wine glass = 2 fluid ounces 1 pint = 2 cups or glasses 1 cup or glass = 8 fluid ounces.

END NOTES

Footnote 1:

From circular No. 85 of a series of statements prepared under the direction of the Secretary of Agriculture, covering the agricultural situation for 1918.

Footnote 2:

The Babcock Test is operated as follows: When the milk has been thoroughly mixed and a true sample has been taken the _pipette_ is filled to the mark by sucking the milk into it until it stands a little above the mark on the stem, then quickly placing a dry finger over the end of the pipette and allowing the milk to escape until it just reaches the mark. The quantity thus measured off is 17.6 c.c. The pipette is then emptied into the _test bottle_ by placing the point in the neck and allowing the milk to flow slowly down the inside of the neck, taking care not to lose any of the milk. Blow the last drops out of the pipette into the bottle.

The _measuring glass_, holding 17.5 c.c., is filled to the mark with _sulphuric acid_ of a specific gravity of 1.82 to 1.83 and this is poured into the milk in the test bottle. The acid is a strong poison and must be handled with care. Pour it slowly down along the wall of the bottle which is held at an angle and turned slowly during the operation.

Now give the bottle a rotary motion to thoroughly mix the milk and the acid, shaking vigorously towards the end of the operation so as to be sure not to leave any of the acid which is heavier than the milk at the bottom of the bottle.

Whirling.—The bottles are then placed in the centrifugal machine and whirled for five minutes at the proper speed—from 600 to 1200 revolutions per minute—according to the diameter of the machine and as stated in the directions which come with the tester. The mixture of milk and acid is hot enough if the whirling is done at once, but if it is allowed to cool the bottles should be placed in hot water of 150 to 170° for about 15 minutes; whirling at full speed for 4 minutes brings all the fat to the top.

Hot water is now added until the bottle is filled almost to the scale on the neck and the bottles are again placed in the machine and whirled at full speed for one minute. Hot water is then again added until the lower end of the fat column is within the scale, preferably at the 1% or 2% mark on the neck of the bottle. Whirl once more for one or two minutes and then read off the percentage of fat on the scale. Each division represents 0.2% fat. The fat column is measured from the lower line between the fat and the water to the point where the top of the fat column touches the wall of the neck. A pair of dividers are handy for measuring the fat column and reading off the percentage of fat in the milk. The bottle with contents should be warm—about 140°—when the measure is taken.

For testing skim milk and cream special forms of test bottles are used—which are described in the circulars coming with the testers and students who desire fuller information are referred to Farrington and Woll's "Testing Milk and its Products," published by the Mendota Book Co., Madison, Wis.

Footnote 3:

The _Acid Test_ depends upon what in the laboratory is called "titration" and makes use of a "burette," a long, graduated measuring tube provided with a pinch-cock. This burette is filled with an alkali solution of known strength, usually a "tenth normal"

solution of caustic soda. A certain amount of the milk to be tested is measured off into a glass or a white porcelain cup. As a 17.6 c.c. pipette belonging to the Babcock test usually is at hand, that may be used for this purpose. A few drops of an _Indicator_ is added to the milk and under constant stirring the soda solution is allowed to drip into it until suddenly it turns pink. The color will quickly disappear, however, and a few more drops of the alkali are added and stirred in several times until a faint but distinct pink color remains for some time. That indicates that the acid in the milk has been neutralized and the amount of the soda solution consumed is then read off on the scale on the burette. By dividing the number of c.c. of the soda solution used by two, the tenths per cent of lactic acid in the milk is found. For example, if it takes 4 c.c. of the soda solution to neutralize 17.6 c.c. milk, the acidity is .2%. This depends upon the fact that 1 c.c. of a tenth normal soda neutralizes .009 gram of lactic acid and that therefore the per cent of acid in the milk is equal to .009 multiplied by the number of c.c. of soda solution used, divided by the number of c.c. of milk and multiplied by 100.

If 50 c.c. of milk is taken instead of 17.6 the calculation is changed accordingly.

Footnote 4:

Farmers' Bulletin No. 602, U. S. Dept. of Agriculture.

Footnote 5:

Butter Color is made of the coloring matter of "Annatto" dissolved in a refined vegetable (salad) oil. The Annatto tree (Bixa Orelana) grows in the tropics and the seed which has a thin coating of this beautiful coloring matter comes mostly from the West Indian Islands, Jamaica, Porto Rico and Guadeloupe. It is perfectly harmless and is used by the natives to flavor and color soup and other foods much as we use tomatoes.

Footnote 6:

The Marschall Rennet Test consists of a graduated cup (a) with a fine hole for an outlet in the bottom. One cubic centimeter of a standard rennet extract is diluted with water in the glass bottle (c). The cup is filled with milk and placed on the corner of the cheese vat, the milk being allowed to run through the fine hole in the bottom of the cup. The moment the surface of the milk reaches the upper mark of the graduation in the cup the diluted rennet extract is added and quickly stirred into the milk with the spattle (d).

When the milk begins to curdle it stops running out. The sweeter the milk is the more will run out before coagulation stops it and the mark on the scale at which it stops indicates the degree of acidity or ripening. The point is to have the milk alike every day and if, for instance, the cheesemaker has found that his cheese is best if he adds the rennet to the milk in the vat when the test shows 2½, he wants to ripen the milk to that degree every day. So, if the test shows 3 or 4, it indicates that the milk is not sufficiently ripened and it should be allowed to stand warm for a longer time before it is set with rennet.

Footnote 7:

The Acidemeter for making an Acid Test is described in Chapter I.

Footnote 8:

Rennet (see under "Ferments" in Chapter I) is prepared from the third division of the stomach of the suckling or milk-fed calf. Fifty years ago cheesemakers used to make their own rennet by soaking salted calves' stomachs in sour whey, and our grandmothers used a piece of a dry, salted stomach to make Junket or "Curds and Whey." About 1868, Christian Hansen, of Copenhagen, Denmark, began the preparation of Commercial Rennet Extract which soon supplanted the home-made rennet in all countries wherever cheese was made. Nowadays rennet in liquid or powder or tablet form for cheesemaking, and Junket Tablets for milk puddings, are prepared pure and of known strength in laboratories and handled by druggists and dealers in dairy supplies.

The fresh stomachs are saved by the farmers or butchers and are either blown up and dried in the air protected from sunlight and rain, or split lengthwise and spread out flat and salted on both sides.

In the laboratory the ferment is extracted by chemicals and a pure, clear liquid extract is prepared, of uniform strength and good keeping quality. Or the extract is condensed into a powder which again is compressed into tablets of great strength.

The ferment acts best when the milk is lukewarm, but it will do the work at temperatures ranging from 50°, or even lower, to 120° F. Strongly pasteurized or sterilized milk will not curdle with rennet, but milk pasteurized at a low temperature is not changed enough

to prevent it from making a firm curd. More rennet does not make a firmer curd but causes the milk to curdle quicker; less rennet makes the process slower. Diluted milk will not curdle firmly, and the failure of milk to make a smooth coagulum of the usual consistency and in the usual time, the temperature being right and the regular amount of a standard rennet being used, is a never-failing proof that something is the matter with the milk. It has been changed from its natural condition by over-heating in pasteurization or by watering or doctoring, or it has not been properly ripened.

The Book of Ice Cream

BY WALTER N. FISK

Cloth, 12 mo

This book is intended to aid the student and the commercial manufacturer in better understanding the principles of making and handling ice cream. It is not primarily intended as a recipe-book, although many recipes are included in the text.

The first five chapters consist in a general discussion of the materials used in the manufacture of ice cream as well as the stabilizers and fillers and flavoring materials. The next chapter deals with the classification of ice creams, and here the recipes are given. The equipment and refrigeration are then explained in a separate chapter, followed by three chapters devoted to the actual making of ice cream.

The concluding pages are taken up with an analysis of the qualities of ice cream and of the bacteriology of its manufacture. Such a discussion should be useful both to the student in the class-room and the progressive manufacturer.

THE MACMILLAN COMPANY Publishers 64-66 Fifth Avenue New York

THE RURAL TEXT-BOOK SERIES

EDITED BY L. H. BAILEY

Butter

BY E. S. GUTHRIE

Professor in the Dairy Department, New York State College of Agriculture, Cornell University

* * * * *

Cloth, 12mo, $1.75.

A practical discussion of the general characteristics of butter, and of all of the problems connected with its manufacture and marketing, together with a brief history of the product. Among the topics considered are the history of butter; composition and food value of butter; cleansing and care of dairy utensils; care of milk and cream; cream separation; grading milk and cream and neutralizing acidity; pasteurization; cream ripening; churning, washing, salting and packing butter; flavors of butter; storage of butter; marketing; whey butter, renovated and ladled butter; margarine, and testing.

The Book of Cheese

BY CHARLES THOM

Mycologist in charge of Microbiological Laboratory, Bureau of Chemistry, United States Department of Agriculture; formerly Investigator in Cheese at Connecticut Agricultural College

AND

WALTER W. FISK

Assistant Professor of Dairy Industry, New York State College of Agriculture at Cornell University

Cloth, 12mo, $1.90.

An exposition of the processes of making and handling a series of important varieties of cheese. The kinds considered are those made commercially in America or widely met in the trade here. The relation of cheese to milk and to its production and composition has been presented in so far as required for this purpose.

After a general statement on cheese, the authors consider the following subjects: The milk in its relation to cheese; Coagulating materials; Lactic starters; Curd making; Classification of cheese; Cheese with sour milk flavor; Soft cheeses ripened by mold; Soft cheeses ripened by bacteria; Semi-hard cheeses; The hard cheeses; Cheddar cheese making; Composition and yield of cheddar cheese; Cheddar cheese ripening; The Swiss and Italian groups; Miscellaneous varieties and by-products; Cheese factory construction, equipment, organization; History and development of the cheese industry in America; Testing; Marketing; Cheese in the household.

A Manual of Milk Products

BY W. A. STOCKING, JR.

Professor of Dairy Bacteriology in the New York State College of Agriculture at Cornell University

Cloth, 12mo, $2.50

This is a very recent addition to the Rural Manual Series under the editorship of L. H. Bailey. The work is intended to serve as a reference book covering the entire subject of milk and its products. There are chapters on The Chemical Composition of Milk, The Factors Which Influence Its Composition, Physical Properties, The Various Tests Used in the Study of Milk, The Production and Handling of Milk, Butter Making, The Cream Supply, Butter Making on the Farm, Cheese Making, and the Bacteriology of Dairy Products.

Milk and Its Products

BY HENRY H. WING Professor of Dairy Husbandry in Cornell University

New Revised Edition, with new illustrations, cloth, 12mo, $1.60

The revolution in dairy practice, brought about by the introduction of the centrifugal cream separator and the Babcock test for fat, by a more definite knowledge regarding the various fermentations that so greatly influence milk, and the manufacture of its products, have demanded the publication of a book that shall give to the dairyman, and particularly to the dairy student, in simple, concise form, the principles underlying modern dairy practice. Such has been Professor Wing's purpose in this work. This is not a new edition of the author's very successful volume published under the same title many years ago; it is, in reality, an entirely new book, having been wholly reset and enlarged by the addition of new matter, both text and illustrations. The author's aim has been at all times to give the present state of knowledge as supported by the weight of evidence and the opinions of those whose authority is highest.

● Transcriber's Notes: ■ Footnotes have been gathered and moved to their own section. ■ Missing or obscured punctuation was silently corrected. ■ Typographical errors were silently corrected. ■ Inconsistent spelling and hyphenation were made consistent only when a predominant form was found in this book. ■ Text that was in: italics is enclosed by underscores (_italics_); bold by is enclosed by "equal" signs (=bold=).

INTRODUCTION

BY UPTON SINCLAIR

Ten years ago, when I was a student at college, I fell a victim to a new and fashionable ailment called “la grippe.” I recollect the date very well, because it was the first time I had been sick in fourteen years—the last difficulty having been the whooping-cough.

I have many times had occasion to recall the interview with the last physician I went to see. I made a proposition, which might have changed the whole course of my future life, had he only been capable of understanding it. I said: “Doctor, it has occurred to me that I would like to have someone who knows about the body examine me thoroughly and tell me how to live.”

I can recollect his look of perplexity. “Was there anything the matter with you before this attack?” he asked.

“Nothing that I know of,” I answered; “but I have often reflected that the way I am living cannot be perfect; and I want to get as much out of my body and mind as I can. I should like to know, for instance, just what are proper things for me to eat——”

“Nonsense,” he interrupted. “You go right on and live as you have been living, and don’t get to thinking about your health.”

And so I went away and dismissed the idea. It was one that I had broached with a great deal of diffidence; so far as I knew, it was entirely original, and I was not sure how a doctor would receive it. All doctors that I had ever heard of were people who cured you when you were sick; to ask one to take you when you were well and help you to stay well, was to take an unfair advantage of the

profession.

So I went on to “live as I had been living.” I ate my food in cheap restaurants and boarding-houses, or in hall bedrooms, as students will. I invariably took a book to the table, and ate very rapidly, even then; frequently I forgot to eat at all in the ardor of my work. I was a worshiper of the ideal of health, and never used any sort of stimulant; but I made it a practice to work sixteen hours a day, and quite often I worked for long periods under very great nervous strain. And four years later I went back to my friend the physician.

“You have indigestion,” he said, when I had told him my troubles. “I will give you some medicine.”

So every day after meals I took a teaspoonful of some red liquor which magically relieved the distressing symptoms incidental to doing hard brain-work after eating. But only for a year or two more, for then I found that the artificially digested food was not being eliminated from my system as regularly as necessary, and I had to visit the doctor again. He gave my ailment another name, and gave me another kind of medicine; and I went on, working harder than ever—being just then at an important crisis in my life.

Gradually, however, to my great annoyance, I was forced to realize that I was losing that fine robustness which enabled me to say that I had not had a day’s sickness in fourteen years. I found that I caught cold very easily—though I always attributed it to some unwonted draught or exposure. I found that I was in for tonsilitis once or twice every winter. And now and then, after some particularly exhausting labor, I would find it hard to get to sleep. Also I had to visit the dentist more frequently, and I noticed, to my great perplexity, that my hair was falling out. So I went on, until at last I was on the verge of a nervous breakdown, and had to drop everything and go away and try to rest.

That was my situation when I stumbled upon an article in the _Contemporary Review_, telling about the experiments of a gentleman named Horace Fletcher. Mr. Fletcher’s idea was, in brief, that by thorough and careful chewing of the food, one extracted from it the maximum of nutriment, and could get along upon a much smaller quantity, thus saving a great strain upon the bodily processes.

This article came to me as one of the great discoveries of my life. Here was a man who was doing for himself exactly what I had asked my physician to do for me so many years previously; who was working, not to cure disease, but to live so that disease would be powerless to attack him.

I went at the new problem in a fine glow of enthusiasm, but blindly, and without guidance. I lived upon a few handfuls of rice and fruit—with the result that I lost fourteen pounds in as many days. At the same time I met a young writer, Michael Williams, and passed the Fletcher books on to him—and with precisely the same results. He, like myself, came near killing himself with the new weapon of health.

But in spite of discouragements and failures, we went on with our experiments. We met Mr. Fletcher himself, and talked over our problems with him. We followed the course of the experiments at Yale, in which the soundness of his thorough mastication and “low proteid” arguments were definitely proven. We read the books of Metchnikoff, Chittenden, Haig and Kellogg, and followed the work of Pawlow of St. Petersburg, Masson of Geneva, Fisher of Yale, and others of the pioneers of the new hygiene. We went to Battle Creek, Michigan, where we found a million-dollar institution, equipped with every resource of modern science, and with more than a thousand nurses, physicians and helpers, all devoting their time to the teaching of the new art of keeping well. And thus, little by little, with backslidings, mistakes, and many disappointments, we worked out our problems, and found the road to permanent health. We do not say that we have entirely got over the ill effects of a lifetime of bad living; but we do say that we are getting rid of them very rapidly; we say that we have positive knowledge of the principles of right living, and of the causes of our former ailments, where before we had only ignorance.

In the beginning, all this was simply a matter of our own digestions, and of the weal and woe of our immediate families. But as time went on we began to realize the meaning of this new knowledge to all mankind. We had found in our own persons freedom from pain and worry; we had noticeably increased our powers of working, and our mastery over all the circumstances of our lives. It seemed to us that we had come upon the discovery of a new virtue—the virtue of good eating—fully as important as any which moralists and prophets have ever preached. And so our interest in these reforms became part of our dream of the new humanity. It was not enough for us to have found the way to health for ourselves and our families; it seemed to us that we ought not to drop the subject until we had put into print the results of our experiments, so that others might avoid our mistakes and profit by our successes.

Historians agree that all known civilizations, empire after empire, republic after republic, from the dawn of recorded time down to the present age, have decayed and died, through causes generated by civilization itself. In each such case the current of human progress has been restored by a fresh influx of savage peoples from beyond the frontiers of civilization. So it was with Assyria, Egypt and Persia; so Greece became the wellspring of art and the graces of life, and then died out; so Rome conquered the world, built up a marvellous structure of law, and then died out. As Edward Carpenter and others have shown us, history can paint pictures of many races that have attained the luxuries and seeming securities of civilization, but history has yet to record for us the tale of a nation passing safely through civilization, of a nation which has not been eventually destroyed by the civilization it so arduously won.

And why? Because when ancient races emerged out of barbarism into civilization, they changed all the habits of living of the human race. They adopted new customs of eating; they clothed themselves; they lived under roofs; they came together in towns; they devised ways of avoiding exposure to the sun and wind and rain—but they never succeeded in devising ways of living that would keep them in health in their new environment.

The old struggle against the forces of nature once relaxed, men grew effeminate and women weak; diseases increased; physical fibre softened and atrophied and withered away; moral fibre went the same path to destruction; dry rot attacked the foundations of society, and eventually the whole fabric toppled over, or was swept aside, to be built up again by some conquering horde of barbarians, which in its turn grew civilized, and in its turn succumbed to the virulent poison that seemed inherent in the very nature of civilization, and for which there seemed to be no antidote.

So much for the past. As to the present, there do not lack learned and authoritative observers and thinkers who declare that our own civilization is also dying out. They point out that while in many directions we have bettered our physical condition, improved our surroundings, and stamped out many virulent diseases (smallpox, the plague and yellow fever, for instance), and have reduced average mortality, nevertheless we have but exchanged one set of evils for another and perhaps more serious, because more debilitating and degenerating set: namely, those manifold and race-destroying evils known as nervous troubles, and those other evils resulting from malnutrition, which are lumped together vaguely under the name of dyspepsia, or indigestion—the peculiar curse of America, the land of the frying-pan.

It is also plain, say the critics of our civilization, that society to-day cannot be regenerated by barbarians. To-day the whole world is practically one great civilization, with a scattering of degraded and dying little tribes here and there. Modern civilization seems to have foreseen the danger of being overrun some day as the ancient civilizations were, and to have forestalled the danger by the inventions of gunpowder and rum, syphilis and tuberculosis.

Are these critics right? I believe that they are, as far as they go; I believe that to-day our civilization is rapidly degenerating; but also I believe that it contains within itself two forces of regeneration which were lacking in old societies, and which are destined ultimately to prevail in our own. The first of these forces is democracy, and the second is science.

To whatever department of human activity one turns at the present day, he finds men engaged in combating the age-long evils of human life with the new weapon of exact knowledge; and their discoveries no longer remain the secrets of a few—by the agencies of the public school and the press they are spreading throughout the whole world. Thus, a new science of economics having been worked out, and the causes of poverty and exploitation set forth, we see a world-wide and universal movement for the abolition of these evils. And hand in hand with this goes a movement of moral regeneration, manifesting itself in a thousand different forms, but all having for their aim the teaching of self-mastery—the replacing of the old natural process of the elimination of the unfit by a conscious effort on the part of each individual to eliminate his own unfitness. We see this movement in literature and art; we see it in the new religions which are springing up—in Christian Science, and the so-called “New Thought” movements; we see it in the great health movement which is the theme of this book, and which claims for its leaders some of the finest spirits of our times.

In the state of nature man had to hunt his own food, so he was hungry when he sat down to eat. But having conquered nature, and accumulated goods, he is able to think of enjoyments, and invents cooks and the art of cookery—which is simply the tickling of his palate with all kinds of stomach-destroying concoctions. And now the time has come when he wishes to escape from the miseries thus brought upon him; and, as before, the weapon is that of exact science. He must ascertain what food elements his body needs, and in what form he may best take them; and in accordance with this new knowledge he must shape his habits of life. In the same way he has to examine and correct his habits of sleeping and dressing and bathing and exercising, in accordance with the real necessities of his body.

This is the work which the leaders of the new movement are engaged upon. To quote a single instance: while I was “living as I had been living” and eating the preparations of ignorant cooks in boarding-houses and restaurants, Dr. Kellogg of Battle Creek was bringing all the resources of modern chemistry and bacteriology to bear upon the problem of the nutrition of man; taking all the foods used by human beings, and analyzing them and testing them in elaborate experiments; determining the amount of their available nutriment and their actual effect upon the system in all stages of sickness and health; the various ways of preparing them and combining them, and the effect of these processes upon their palatability and ease of digestion. Every day for nine years, so Kellogg told me, he sat down to an experimental meal designed by himself and prepared by his wife; and the result is a new dietary—that in use at the Battle Creek Sanitarium—which awaits only the spread of knowledge to change the ways of eating of civilized man.

This new health knowledge has been amassed by many workers and, as in all cases of new knowledge, there is much chaff with the grain. There are faddists as well as scientists; there are traders as well as humanitarians. It seemed to us that there was urgently needed a book which should gather this new knowledge, and present it in a form in which it could be used by the average man. There have been many books written upon this; but they are either the work of propagandists with one idea—containing, as we have proved to our cost, much dangerous error; or else the work of physicians and specialists, whose vocabulary is not easily to be comprehended by the average man or woman. What we have tried to write is a book which sets forth what has been proved by investigators in many and widely-scattered fields; which is simple, so that a person of ordinary intelligence can comprehend it; which is brief, so that a busy person may quickly get the gist of it; and which is practical, giving its information from the point of view of the man who wishes to apply these new ideas to his own case.

Michael Williams was recently persuaded to give a semi-public talk on the subject before an audience of several hundred professional and business people. He was compelled to spend the rest of the evening in answering the questions of his audience; and listening to these questions, I was made to realize the tremendous interest of the public in the practical demonstration which Mr. Horace Fletcher has given of the idea of Metchnikoff, that men and women to-day grow old before they ought to do so, and that the prime of life should be from the age of fifty to eighty. A broken-down invalid at forty-five, Mr. Fletcher was at fifty-four a marvel of strength—and at fifty-eight he showed an improvement of one hundred per cent. over his tests at the age of fifty-four; thus proving that progressive recuperation in the so-called “decline of life” might be effected by followers of the new art of health.

As a result of this address, Williams was invited by the president of one of the largest industrial concerns in the country to lecture to his many thousands of employees on the new hygiene; his idea being to place at their disposal the knowledge of this new method of increasing their physical and mental efficiency.

For business men and women, indeed, for workers of all kinds, good health is capital; and the story of the new hygiene is the story of the throwing open of hitherto unsuspected reserve-stores of energy and endurance for the use of all.

In writing upon this subject, the experiences most prominent in our minds have naturally been those of ourselves, of our wives and children, and of friends who have followed in our path. As the setting forth of an actual case is always more convincing than a general statement, we have frequently referred to these experiences, and what they have taught us. We have done this frankly and simply, and we trust that the reader will not misinterpret the spirit in which we have done it. Mr. Horace Fletcher has set the noble example in this matter, and has been the means of helping tens of thousands of his fellow men and women.

[Illustration: MR. UPTON SINCLAIR AND MR. MICHAEL WILLIAMS Resting from their favorite exercise.]

I have sketched the path by which I was led into these studies; there remains to outline the story of my collaborator. Williams is the son of a line of sailors, and inherited a robust constitution; but as a boy and youth he was employed in warehouses and department stores, and when he was twenty he went to North Carolina as a tuberculosis patient. Returning after two years, much benefited by outdoor life, he entered newspaper work in Boston, New York, and elsewhere, and kept at it until four years ago, when again he fled South to do battle with tuberculosis, which had attacked a new place in his lungs. After a second partial recuperation, he went to San Francisco. At the time of the earthquake he held a responsible executive position, and his health suffered from the worry and the labors of that period. A year later there came the shock and exposure consequent upon the burning of Helicon Hall. Williams found himself hovering upon the brink of another breakdown, this time in nervous energy as well as in lung power. A trip to sea failed to bring much benefit; and matters were seeming pretty black to him, when it chanced that a leading magazine sent him to New Haven to study the diet experiments being conducted at Yale University by Professors Chittenden, Mendel and Fisher. He found that these experiments were based upon the case of Horace Fletcher, and had resulted in supporting his claims. This

circumstance interested him, suggesting as it did that he himself might have been to blame for his failure with Mr. Fletcher's system. So he renewed the study of Fletcherism, and later on the same magazine sent him to Dr. Kellogg's institution at Battle Creek, with the result that he became a complete convert to the new ideas. Like a great many newspaper men, he had been a free user of coffee, and also of alcohol. As one of the results of his adoption of the "low proteid" diet, and of the open-air life, he was able to break off the use of all these things without grave difficulty. A bacteriological examination recently disclosed the fact that his lungs had entirely healed; while tests on the spirometer showed that his breathing capacity was far beyond that of the average man of his weight and size. In less than three months, while at the Battle Creek Sanitarium, tests showed a great gain in the cell count of his blood, and in its general quality. Also, his general physical strength was increased from 4635 units to 5025, which latter figure is well above the average for his height, 68.2 inches.

In conclusion, we wish jointly to express our obligation to Mr. Horace Fletcher, to Dr. J. H. Kellogg, to Professor Russell H. Chittenden, to Professor Lafayette B. Mendel, and to Professor Irving Fisher for advice, criticism and generous help afforded in the preparation of some of the chapters of this book. The authority of these scientists, physicians and investigators, and of others like Metchnikoff, Pawlow, Cannon, Curtis, Sager, Higgins and Gulick, whose works we have studied, is the foundation upon which we rest on all questions of fact or scientific statement. They are the pathbreakers and the roadbuilders,—we claim to be simply guides and companions along the journey to the fair land of health. The journey is not long, and the road is a highway open to all.

I

THE BATTLE OF THE BLOOD

The new ideas of living which are the subject of this book have proceeded from investigation of the human body with the high-power microscope. The discoveries made, which have to do, not so much with the body itself as with the countless billions of minute organisms which inhabit the body, may be best set forth by a description of the blood. "The blood is the life," says Exodus, and modern science has confirmed this statement. From the blood proceeds the life of all the body, and in its health is the body's health.

If you should prick your finger and extract a drop of your own blood, and examine it under a microscope, you would make the fascinating discovery that it is the home of living creatures, each having a separate and independent existence of its own. In a single ounce of blood there are more of these organisms than there are human beings upon the face of the globe. These organisms are of many kinds, but they divide themselves into two main groups, known as the red corpuscles and the white.

The red corpuscles are the smaller of the two. The body of an average man contains something like thirty million of millions of these corpuscles; a number exceeding the population of New York and London are born in the body every second. They are the oxygen conveyers of the body; the process of life is one of chemical combustion, and these corpuscles feed the fire. No remotest portion of the body escapes their visitation. They carry oxygen from the lungs and they bring back the carbon dioxide and other waste products of the body's activities. They have been compared to men who carry into a laundry buckets of pure water, and carry out the dirty water resulting from the washing process.

The other variety of organisms are the white cells or leucocytes, and it is concerning them that the most important discoveries of modern investigators have been made. The leucocytes vary in number according to the physical condition of the individual, and according to their locality in the body. Their function is to defend the body against the encroachments of hostile organisms.

We shall take it for granted that the reader does not require to have proven to him the so-called "germ theory" of disease. The phrase, which was once accurate, is now misleading, for the germ "theory" is part of the definite achievement of science. Not only have we succeeded in isolating the specific germ whose introduction into the body is responsible for different diseases, but in many cases, by studying the history and behavior of the germ, we have been able to find methods of checking its inroads, and so have delivered men from scourges like yellow fever and the bubonic plague.

THE DEFENSES OF THE BODY

An experiment that is often tried in operating rooms furnishes a vivid illustration of the omnipresence of these invisible, yet potent, foes of life. In order to impress upon young surgeons the importance of maintaining antiseptic conditions, they are instructed to thoroughly wash their hands and arms in antiseptic soap and water; then they are told to leave their arms exposed for a few minutes, after which a microscopic examination of the bared skin will result in exposing the presence of myriads of germs. Many of

these are, of course, harmless; some are even “friendly”—since they make war upon the dangerous kinds. But others are the deadly organisms which find lodgment in the lungs and cause pneumonia and tuberculosis; or the thirty odd varieties of bacilli which cause the various kinds of grippe and influenza and “colds,” which plague the civilized man; or others which, finding entrance into the digestive tract, are the cause of typhoid and other deadly fevers.

So it appears that we live within our bodies somewhat in the same fashion as isolated barons lived in their castles in the Dark Ages, beleaguered constantly by hordes of enemies that are bent upon our destruction—these being billions upon billions of disease germs. Every portion of the body has its defenses to protect it against these swarms. The skin is germ-tight in health; and each of the gateways to the interior of the body has its own peculiar guard—tears, wax, mucous membrane, etc. As Dr. Edward A. Ayers points out,—“Many of these entrances are lined with out-sweeping brooms—fine hairs similar to the ‘nap’ or ‘pile’ of carpet or plush—which constantly sweep back and forth like wheat stalks waving in the breeze. You cannot see them with the low-powered eye, but neither can you see the germs. They sweep the mucous from lungs and throat, and try to keep the ventilators free from dust and germs. Behind the scurf wall and the broom brigade of the mucous membranes, the soldier corpuscles of the blood march around the entire fortress every twenty-eight seconds” (the time occupied by the blood in its circulation through the body).

HEALTHY BODIES ARE GERM-PROOF

And again (to quote another authority, Dr. Sadler), “All the fluids and secretions of the body are more or less germicidal. The saliva, being alkaline, discourages the growth of germs requiring an acid medium. The normal gastric juice of a healthy stomach is a sure germ-killer. In the early part of digestion, lactic acid is present, and there soon appears the powerful hydrochloric acid, which is a most efficient germicide....

“The living, healthy tissues of the body are all more or less germicidal; that is, they are endowed with certain protective properties against germs and disease. This is true of many of the other special secretions, like those found in the eye and elsewhere in the body, when they are normal. The blood and lymph, the two great circulating fluids of the body, are likewise germicidal. In some conditions of disease, there may be found various substances in the blood which can destroy germs.”

THE WHITE CELLS ON GUARD

And this definitely brings us to the other kind of inhabitants of the human blood, the leucocytes, or white blood corpuscles,—and so to the germ theory of health, which science is showing to be no less true than the germ theory of disease. In their natural state these cells are transparent, spherical forms of the consistency of jelly drops, which float in the bloodstreams or creep along the inner surface of the vessel. Their function was for a long time not understood; the discovery of the real facts, perhaps the most epoch-making discovery ever made concerning the human body, the world owes to the genius of Metchnikoff, the head of the Pasteur Institute of Paris. These cells are the last reserves of the body in its defense against the assault of disease. Whenever, in spite of all opposition, the hostile germs find access either to the blood or to the tissue, the white cells rush to the spot, and fall upon them and devour them.

In their fight against the hordes of evil bacteria that invade the blood, where the battles are waged, the body’s defenders have four main ways of battling. Again we quote from Dr. Ayers: “The blood covers some germs with a sticky paste, and makes them adhere to one another, thereby anchoring them so that they become as helpless as flies on fly paper. The paste comes from the liquid of the blood, the plasma. Another blood-weapon (the ‘lysins’) dissolves the germs as lye does. A third means of defense is the ability of the white blood corpuscles to envelop and digest the living germs. One white cell can digest dozens of germs, but it may mean death to the devouring cells.

The fourth and recently discovered weapon, or ammunition, of the blood is the opsonins. Wright and Douglas in London in 1903 coined the word, which comes from the Latin _opsono_: “I cook for the table,” “I prepare pabulum for.” This is precisely what the opsonins do in the blood. They manifest this beneficial activity when invading disease germs appear. They attract white blood cells to the germs and make the bacteria more eatable for the cells. They are appetizers for the white blood cells; or sauces, which help the white blood cells to eat more of the bacteria than they could do without this spur to their hunger. Wright and Douglas demonstrated beyond peradventure the ability of the white blood cells to eat a larger number of bacteria when the latter are soaked in opsonins. They also showed that this opsonic sauce, or appetizer, which stimulates the blessed hunger of the white blood cells for disease bacteria, could be artificially produced, and hypodermically introduced into a patient’s blood, thus increasing that blood’s power of defense by raising the quantity of opsonins. They also worked out a practical laboratory technique by means of

which the opsonins can be measured, or counted, with a considerable degree of exactitude, thereby making it possible to estimate within limits of accuracy any one's ability to resist bacterial invasions. If the blood is rich in opsonins, its power to fight disease is strong. Opsonins are now inoculated into the blood at several institutions, notably McGill University in Montreal, and at the Battle Creek Sanitarium.

HOW THE WHITE CELLS DO THEIR WORK

The process by which the white cells fight for us may be watched in the transparent tissue of a frog's foot or the wing of a bat. If a few disease germs are introduced into this tissue, the white cells may be seen to accumulate on the wall of the blood vessel just opposite where the germs have entered. "Each cell begins to push out a minute thread of its tissue," writes Dr. Kellogg, in describing the process, "thrusting it through the wall of its own blood vessel. Little by little the farther end of this delicate filament which has been pushed through the wall grows larger and larger, while the portion of the cell within the vessel lessens, and after a little time each cell is found outside the vessel, and yet no openings are left behind. Just how they accomplish this without leaving a gap behind them is one of the mysteries for which Science has for many years in vain sought a solution. The vessel wall remains as perfect as it was before. Apparently, each cell has made a minute opening and has then tucked itself through, as one might tuck a pocket handkerchief through a ring, invisibly closing up behind itself the opening made. Once outside the vessel, these wonderful body-defenders, moving here and there, quickly discover the germs and proceed at once to swallow them. If the germs are few in number, they may be in this way destroyed, for the white cells not only swallow germs, but digest them. If the number is very great, however, the cells sacrifice themselves in the effort to destroy the germs, taking in a larger number than they are able to digest and destroy. When this occurs, the germs continue to grow; more white cells make their way out of the blood vessels, and a fierce and often long-continued battle is waged between the living blood cells and the invading germs."

Now, it must be understood that this description is not the product of any one's imagination, but is a definitely established fact which has been studied by scientists all over the world. Because of the importance of the discovery, and of the new views of health to which it leads, we have placed a picture of this "battle of the blood" at the front of this book. It shows the leucocytes of the human body in conflict with the germs of influenza: the black dots being the germs, and the larger grayish bodies the leucocytes. We have chosen a photograph rather than a drawing, so that the reader may realize that he is seeing something which actually has existence. We request him to study the picture and fix it upon his mind, for it is not too much to say that from it is derived every principle of health which is set forth in the course of this book.

THE PROBLEM OF HEALTH

The human body is a complex and intricate organism, in some wonderful and entirely incomprehensible way integrating the activities of all these billions of other living organisms. Each and every one of these latter has its function to fulfill, and the life of the individual body is a life of health so long as the unity of all its organisms is maintained. Outside of the body are millions of hostile organisms assaulting it continuously; and the problem of health is the problem of enabling it to make headway against its enemies for as long a period as possible. Every act of a human being has its effect upon this battle; at every moment of your life you are either strengthening the power of your own organism or strengthening your enemies. Once the organism is unable to beat back its enemies, health begins to fail and death and complete disintegration is the ultimate result.

It must be understood that the peril of these hostile germs is not merely that they devour the substance upon which the body's own organisms have to be nourished. If that were all, they might remain in the body as parasites, and by taking additional nourishment a man might sustain life in spite of them. Nor is it even that they multiply with such enormous rapidity; the peril is that they throw off as the products of their own activity a number of poisons, which are as deadly to the human body as any known. These poisons are produced much more rapidly than they can be eliminated from the system, and so they fill the blood, and death ensues.

Thus the problem becomes clear. In the first place, what can we do to keep disease germs from securing entrance to the body; and second, what can we do to strengthen the body's army of defense so that the fate of any which do find entrance may be immediate destruction?

HEALTH, LIKE DISEASE, IS CATCHING

In actual practice it is found that the second problem is by far the more important one. Some germs we can avoid. If we boil all the water that we drink we will not be very apt to have typhoid. If we exterminate rats and mosquitoes and flies and fleas, we will not have yellow fever, or malaria, or plague. But we cannot hope to do this at present in the case of such diseases as, for instance,

consumption, grippe, and influenza. If we live in a city, we take into our lungs and throat millions of the germs of these diseases every day. Therefore the one hope that is left is to keep ourselves in such a condition of health that the army of our bodies shall be able to destroy these germs. When the blood is in a healthy condition, the white cells are numerous, powerful, and active, but when the blood flows stagnantly, or when it is impoverished, then the white cells are few and the forces of disease obtain a foothold.

Healthy men can go through many epidemics with impunity. Because the Japanese army was an army of healthy men, its death rate from those diseases which usually follow in the wake of all armies was lower than the world had ever known before. Robert Ingersoll once said that if he had been God and had made the world, he would have made health “catching,” and not disease. As a matter of fact, health is catching. It abounds in the very air we breathe, in the water we drink, in the movements of every muscle and the play of every fibre and nerve of the body; it comes from and is nourished by each and every one of the bodily actions and functions; while disease is only secured by persistent transgressions of the proper way of living, and by injurious habits and customs that result in lowering the “vital resistance.”

This vital resistance is the innate power of the body to keep itself strong; its very lifeforce. This is what we mean when we say that this or that person has “a good constitution,” or has “a weak constitution.” This is the capital in the bank of each individual life, placed there by Nature at the birth of that life, and increased or diminished by each and every action of our bodies, and also of our minds. As Rokitansky, the eminent German scientist, said, “Nature heals. This is the first and greatest law of therapeutics—one which we must never forget. Nature creates and maintains, therefore she must be able to heal.”

Many of the most notable discoveries and experiments of modern science concur in demonstrating that the natural and innate healing power of the body is man’s greatest resource in combating disease and maintaining health. It is the body itself which cures the sick man; his own vitality, and not the drug or medicants which he may take. These may assist the healing process, but they do not set going the healing processes themselves. More often, indeed, they are distinct detriments. They stamp out or banish the distressing symptoms of ailments, and thus in effect they silence the signal bells of danger which the body rings at the approach of disease.

Modern science has turned its forces upon this question of maintaining at its highest potentiality the ability of the body to resist disease. All the habits of the human race have been investigated in the light of this idea, and some have been found to be wise and others to be unwise. These conclusions, with the evidence therefor, are the subjects of our book.

OUR FOOD IS THE CHIEF FACTOR

It has been found that the most important problems connected with health are those of nutrition—the questions of what and when and how and how much food we ought to eat.

Every language under the sun contains a prayer somewhat similar to that which we have in the Anglo-Saxon tongue, “Give us this day our daily bread.” If we stop to think for a moment, we realize that next to the air we breathe, and the water we drink, our food is the most important consideration in the maintenance of life. All this is the veriest commonplace; yet the fact remains that it is very rarely indeed that we do stop to think upon the subject of our food. It is something that we take for granted, like life itself. In the regular routine of our days our meals become fixed habits, and the taking of food an almost involuntary custom. It requires some extraordinary event to arouse us to a just appreciation of the importance of knowledge on this subject. Or else the coming of one of the myriad forms of digestive diseases will serve the purpose of introducing the subject to our notice.

Our blood is made directly from what we eat, and that old Saxon proverb is true which says that every man has lain in his own trencher. Man is his food. Each human body is made by chemical action from its food. All our actions and all our thoughts come from what we eat, even as the movements of machinery proceed from the coal fed into the boilers of the engine which operate the machine. If we eat the right food, namely, the food which contains the elements our bodies require in the proper proportions, we repair all waste, replace broken down tissue and supply ourselves with physical and mental energy for our toils and joys in life; while if we eat the wrong foods we quickly injure our delicate though powerful physical and mental machinery.

All this would seem to be obvious; yet most people would grant that they have still much to learn concerning what really constitutes the best foods, and about the best ways of preparing, or making, or using those foods. Few of us possess anything more definite to guide us in our eating than the habits we acquired as children, or habits picked up in later life from following the example of our friends, or the food fashions of the day—for there are such things as fashions in foods and in the eating of foods, even as there are fashions in clothes and the making and wearing thereof. In this place it is proposed to study the subject of food from one standpoint,

namely, its effect upon the Battle of the Blood; its relation to the vital resistance of the body whereby health is maintained.

II

HOW TO EAT: THE GOSPEL OF DIETETICS ACCORDING TO HORACE FLETCHER

We shall first of all see what modern science has to tell us concerning the question of _how_ we ought to eat.

It may not seem possible that anything essential remains to be said at this late day on the subject of one of the commonest and decidedly most necessary of all human acts. That there should be knowledge of the utmost importance to learn regarding the actions and movements of the tongue, the teeth, and the jaws, may come with as much surprise to the majority of our readers as it did to us when we first hit upon this disturbing, but illuminating, fact.

The act of eating is the starting point of the long series of processes whereby our bodies are nourished. It is the only act of them all which lies within our control. We can directly supervise the work of our mouths; we can watch over the action of the teeth, and tongue, and palate; but we can not supervise the work of the stomach, or of the intestinal tube. Once we have swallowed our food, our mastery over it has ceased—except for some hit-or-miss participation in the further processes of its digestion by means of pills or potions. Realizing this, we come to recognize the basic importance of knowing the right way of eating.

THE STORY OF HORACE FLETCHER

This knowledge the world owes to Horace Fletcher, the American business man who has made many of the greatest physiologists of our times embark upon years-long series of experiments and inquiries into the problems of man’s nutrition. As a result, the text-books of physiology are now being rewritten; and as a further result, tens of thousands of men and women, among them some of the best known authors, physicians, clergymen, military men, and business men of both Europe and America, have been restored to health by the knowledge of how to eat their food.

[Illustration: MR. HORACE FLETCHER, Whose books on dietetics and good health were the forerunners of the present movement.]

This knowledge Mr. Fletcher gained at the very door of death, and in no more interesting and striking fashion could the importance of it be shown than by the relation of his remarkable case.

At the age of forty-five, after a varied and adventurous career, as miner, and explorer, and sailor, and hunter, Mr. Fletcher had won wealth, and retired from his business in order to devote himself to long-cherished interests in art and philosophy. He was still comparatively young, he was a member of many clubs, he had warm friends in all the capitals and countrysides of the world (Mr. Fletcher being one of the most untiring of globe-trotters), and in all ways except one he was equipped and ready for a long life of ease and enjoyment.

The one way in which he was not equipped was—in health.

HOW A STRONG MAN BROKE DOWN

Once he had been a man of robust physique, a champion gymnast and athlete; he had been president of the far-famed Olympic Club in San Francisco (which he founded, and where the pugilist Corbett was discovered), and had won plaudits even from famous professionals for his prowess with the gloves.

But he had overdrawn his account at the bank of life. He had expended more vital resistance than he had stored up; to such an extent, indeed, that when Mr. Fletcher went to the insurance companies at the time he retired from business he was rejected by them all; he was obese; he was suffering from three chronic diseases, and he was dying fast. Such was the verdict given by the skilled and experienced medical examiners of the life insurance companies. And instead of entering upon a long life of ease and enjoyment, he was thus condemned, seemingly, to a short life of invalidism and suffering.

FIGHTING FOR LIFE

But Mr. Fletcher declined to accept any such decision as that. He decided that he would regain his health—not that he would _try_ to regain his health, but that he _would_ regain his health.

He first turned to the physicians. Possessed of wealth, he was able to secure the services of many of the most able specialists of the world. He visited the most celebrated “cures” and “springs” and sanitariums of Europe and America. Nothing availed. He found passing relief now and then, but no permanent good. He gained no health, in other words, but obtained merely temporary abatement of this or of that disease.

Then he turned to himself. He began the study of his own case. As he attributed most of his bodily woes to faulty habits of eating, the subject of nutrition became uppermost in his studies. He was, coincidentally, deeply immersed and interested in the study of practical philosophy; and in a very remarkable fashion these two subjects, these two interests, nutrition and practical philosophy, became fused into one subject, supplementing and completing each other and jointly forming the burden of the message of Hope, of the tidings of great joy, which it became the mission of Horace Fletcher to deliver to mankind.

MR. FLETCHER’S DISCOVERY

He discovered, or rather rediscovered, and applied, two great and simple truths:

First, that the complete chewing of all food, both liquid and solid, whereby a process of involuntary swallowing is established, foods being selected in accordance with individual tastes, is by far the most important and most necessary part of human nutrition. It is the key that unlocks the door of health, and opens the way to the real hygienic life.

Second, that nothing poisons the body, and aids the forces of disease, more than worry—which Mr. Fletcher has named Fearthought. It is our nature to look forward, to anticipate. We can anticipate in two ways—anticipate evil, or anticipate good. The first way is to use fearthought; the second way is to use forethought. Forethought will produce cheerfulness and health, even as unspoiled rose seeds will produce roses. Fearthought will produce disease and trouble, even as the germs of putrefaction will produce sickness and death.

So great an authority in philosophy and psychology as William James has given the sanction of his use to Mr. Fletcher’s phrases; and has also named him as a shining example of those exceptional men who find in some mental idea a key to unlock reservoirs of hidden and unsuspected energy. While there is no doubting the fact that Horace Fletcher is decidedly an exceptional man, yet the records prove that his key is not merely for the use of exceptional people, but that it is one susceptible of being used by everybody possessing willpower enough to enable them to say “yes” when offered something good.

Like other great discoveries, Mr. Fletcher’s discovery of the right way to eat came partly as an accident. Happening to be in Chicago at a time when his friends were all away, and being forced to stay in the city, he took to lingering over his meals in order to pass away the time. He began to taste every spoonful of soup, to sip every mouthful of anything liquid, with great deliberation, noting the different tastes and searching out new flavors.

He chewed each morsel of meat or bread or fruit or vegetable until, instead of being gulped down, it was drawn in easily by the throat. And in this manner did he stumble upon his pathway to deliverance. He had not been “toying” with his food—as he then considered he was doing—for more than a few weeks before he noticed that he was losing a great deal of superfluous fat, that he was eating less, but with far greater enjoyment, than ever before in his life, that his taste for simpler foods increased as his taste for highly seasoned and complex dishes decreased, and that he was feeling better both physically and mentally than he had felt in many years.

THE MAGIC OF MASTICATION

What did these things mean? Some hidden virtue in the food he was eating? Some hitherto quite unsuspected tonic in the smoke of Chicago? Or a lesson in health furnished by the “how” of his eating? At this point there flashed through Mr. Fletcher’s memory the story of Gladstone’s advice to his children to chew each morsel of food thirty-two times (once for each tooth in their heads) if they would preserve their health. In that moment, Mr. Fletcher began his investigation of the many processes that go to make up the simple act of mastication, an investigation which has now been going on for more than ten years, and which has resulted in directing public attention to the supremely important subject of nutrition with more emphasis, and in the arousing of more general interest and the production of more telling effect than any other circumstance or event has done in the history of physiologic science. The word “Fletcherizing” was first applied by Dr. J. H. Kellogg, of Battle Creek, after the analogy of “pasteurizing,” in describing the act of mastication as recommended by Mr. Fletcher. “Fletcherism,” as Mr. Fletcher’s system of mental science and of physical culture through mastication has come to be known, after first being for years a stock jest of the newspaper funnyman, has

now been recognized, even by those scientists who detest all “isms,” as a most valuable bridge from the land of bad food habits and disease to the land of good food habits and health.

The bridge certainly afforded its builder a passage from one region to the other. Following a constant improvement in his general condition, beginning almost simultaneously with the adoption of his new way of life, Mr. Fletcher is to-day one of the strongest and most enduring men alive. Tests of his strength and endurance made at the Yale gymnasium at different times prove beyond a doubt that this is so. The following is a quotation from the report of Dr. William G. Anderson, director of the Yale Gymnasium:

DR. ANDERSON’S REPORT

“In February, 1903, I gave to Mr. Horace Fletcher the exercises used by the ‘Varsity’ crew. He went through these movements with ease and showed no ill effects afterwards. At that time Mr. Fletcher weighed 157½ pounds, and was in his fifty-fifth year. On June 11, 1907, Mr. Fletcher again visited the Yale Gymnasium and underwent a test on Professor Fisher’s dynamometer. This device is made to test the endurance of the calf muscles.

“The subject makes a dead lift of a prescribed weight as many times as possible. In order to select a definite weight, the subject first ascertains his strength on the Kellogg mercurial dynamometer by one strong, steady contraction of the muscles named—and then he finds his endurance by lifting three-fourths of this weight on the Fisher dynamometer as many times as possible at two or three second intervals. One leg only is used in the lift, and as indicated, the right is usually chosen.

“Mr. Fletcher’s actual strength as indicated on the Kellogg machine was not quite four hundred pounds, ascertained by three trials. In his endurance test on the Fisher machine he raised three hundred pounds three hundred and fifty times and then did not reach the limit of his power.

“Previous to this time, Dr. Frank Born, the medical assistant at the Gymnasium, had collected data from eighteen Yale students, most of whom were trained athletes or gymnasts. The average record of these men was 87.4 lifts, the extremes being 33 and 175 lifts.

[Illustration: MR. HORACE FLETCHER Making a World’s Record on the Dynamometer without previous training. Dr. William G. Anderson, Director of the Yale Gymnasium, in the Background.]

“You will notice that Mr. Fletcher _doubled_ the best record made previous to his feat, and numerous subsequent tests failed to increase the average of Mr. Fletcher’s competitors. Mr. Fletcher informs me that he had done no training nor had he taken any strenuous exercise since February, 1907. On two occasions only during the past year he reports having done hard work in emergencies; once while following Major-General Wood in the Philippines in climbing a volcanic mountain through a tropical jungle on an island near Mindanao for nine hours; and once wading through deep snow in the Himalayan Mountains, some three miles one day and seven miles the next day, in about as many hours. This last emergency experience came through being caught in a blizzard near Murree, in Northern India, at 8500 feet elevation, on the way to the vale of Kashmir. These two trials represented climatic extremes, and Mr. Fletcher states that neither the heat nor the cold gave him discomfort, a significant fact in estimating physical condition.

“Before the trial on the Fisher machine, the subject’s pulse was normal (about 72); afterwards it ran 120 beats to the minute. Five minutes later it had fallen to 112. No later reading was taken that day.

“The hands did not tremble more than usual under resting conditions, as Mr. Fletcher was able to hold in either hand immediately after the test a glass brimming with water without spilling a drop. The face was flushed, perspiration moderate, heart action regular and control of the right foot and leg used in the test normal immediately following the feat. I consider this a remarkable showing for a man in his fifty-ninth year; 5 feet, 6½ inches in height, weighing 177½ pounds and not in training.”

In order to make a more thorough test of Mr. Fletcher’s power of endurance under varying degrees of physical strain, he underwent on the 17th, 18th, 19th, 21st and 22nd of June, 1907, a number of other exceedingly severe tests, of which Dr. Anderson says: “After each test the respiration and heart action, while active, were healthy, and, under such conditions, normal.

“There was not the slightest evidence of soreness, stiffness or muscular fatigue either during or after the six days of the trials. Mr. Fletcher made no apparent effort to conceal any evidence of strain or overwork and did not show any. He informs me that he felt no distress whatever at any time. Should any one wish to become more familiar with the strenuousness of the movements selected, let him try them. The effort will be more convincing than any report.

“During the thirty-five years of my own experience in physical training and teaching, I have never tested a man who equalled Mr. Fletcher’s record.

“The later tests, given in June, 1907, were more taxing than those given in 1903, but Mr. Fletcher underwent the trials with more apparent ease than he did four years ago.

“What seems to me to be the most remarkable feature of Mr. Fletcher’s test is that a man nearing sixty years of age should show progressive improvement of muscular quality merely as the result of dietetic care and with no systematic physical training. The method of dietetic care, too, as given by Mr. Fletcher, is so unusual that the results seem all the more extraordinary. He tells me that during the four and a half years intervening between the first and the recent examinations he has been guided in his choice of foods and in the quality also, entirely by his appetite, avoiding as much as possible any preconceived ideas as to the values of different foods or the proportions of the chemical constituents of the nourishment taken.

“During this four year period he has more than ever catered to his body nourishment in subservience to instinctive demand. He has especially avoided eating until appetite has strongly demanded food, and has abstained from eating whenever he could not do so in comfort and enjoyment. Mastication of solid food and sipping of liquids having taste to the point of involuntary swallowing, according to his well-known theory of thoroughness in this regard, has also been faithfully followed.

“There is a pretty good evidence that taking food as Mr. Fletcher practices and recommends limits the amount ingested to the bodily need of the moment and of the day, leaving little or no excess material to be disposed of by bacterial agency. This might account for the absence of toxic products in the circulation to depress the tissue.

“The possible immunity from lasting fatigue and from any muscular soreness, resulting from the unaccustomed use, and even the severe use, of untrained muscles is of utmost importance to physical efficiency.

“My own personal observance and trial of Mr. Fletcher’s method of attaining his surprising efficiency, strengthened by my observation of the test-subjects of Professors Chittenden and Fisher who have come under my care meantime, lead me to endorse the method as not only practical but agreeable. As Mr. Fletcher states, both the mental and mechanical factors in selecting and ingesting food are important, the natural result of the care being a wealth of energy for expression in physical exercise.”

FLETCHERISM

So much for Horace Fletcher’s own case.

Yet when he first announced his discovery, his own family laughed at him, and the medical world called him crank. But by quiet, sane, persistent work—by applying to the propaganda of his idea the same methods that had brought him success in business, he succeeded in impressing the scientific world with the value of his method.

An extensive literature has grown up around Mr. Fletcher’s own books. The most important medical bodies in Europe and America have invited him to lecture before them. Hospitals in larger cities have printed his own code of the rules of mastication for distribution. And no large sheet of paper was required, for the whole system could be printed on a postal card, and room would be left for a picture of its author.

Why is complete mastication the best way of eating? Why does its practice lead to recovery of lost health, or increase of health; to increase of strength, to increase of endurance. Is it not a very tedious method, and thus of more trouble than its promised benefits are worth? Does it not waste time? Does it not lead to loss of enjoyment of food?

These are a few of the questions which a discussion of Fletcherism invariably arouses. We speak with a deep conviction of truth when we say that Fletcherism leads to saving of time, instead of loss of time; that it brings increase of sensuous enjoyment of food instead of decrease of it; and that if it is tedious or a bore, then it is not Fletcherizing. The very essence of Fletcherism is the dropping of worry, the elimination of stress and strain. If you do as Fletcher says, instead of doing as somebody says that Fletcher says, you will chew for taste, and not for time; you will take a crust of bread, or a morsel of potato, for instance, into your mouth and roll it with your tongue, and press it against the roof of your mouth, and pass it to and fro, and crunch it, and crush it; and all the while you will not be counting the chews, nor even thinking about chewing, but on the contrary you will be thinking of the taste of the morsel, and seeking that taste—and finding it.

Yes, finding it, even in a crust of bread or in a morsel of potato, in those humble foods which the most of us seem to take more as matters of habit; for by giving the saliva in the mouth a chance to fulfill the work for which it is put in our mouths by nature, we find that the starch in the bread and in the potato is turned into a sweet, toothsome and partly digested morsel of sugar.

Here is a point that answers another of the questions which arose a paragraph or so back. This turning of the starch in bread into sugar by the action of saliva is only one of the numerous acts of digestion which is accomplished in the mouth by the teeth, the tongue, the palate, and the various kinds of juices, or saliva, which are in the mouth. Horace Fletcher pointed out, and medical science now confirms his assertions, that many of the most important parts of the digestive process are meant by nature to be carried out in the first three inches of the alimentary canal. And this is the only place in all the thirty feet or so of the alimentary canal where digestion is in our own control. If we bolt or insufficiently masticate our food, these mouth processes of digestion are simply not accomplished; and for this the whole system suffers sooner or later. The stomach and the intestines are called on to do a great deal of extra work, and much of this extra work is of a kind which they are unable to do. Consequently, what food can not be digested must decompose in the intestines, with the consequent production of poisonous fluids and gases which permeate the body. The whole machinery of digestion is thrown out of gear. All the various germs of disease race to be first to enter the disarranged mechanism, as criminals rush to a city that is in disorder. The blood not being as well nourished as it should be, the white army of the soldiers of the body begin to weaken and to die, and the forces of disease penetrate through their warding lines and attack the fort of life from many sides, or else concentrate their strength in the form of some virulent sickness.

Thorough mastication, on the other hand, means the reverse of these conditions. Almost incredible seem the hundreds of stories which we personally know to be true of men and women who have used Mr. Fletcher's method as a means to enter the land of good health. In the opinion of Dr. Kellogg of Battle Creek, "There is no doubt that thorough mastication of food solves more therapeutic problems than any other thing that can be mentioned. It solves the whole question of the right combination of foods; solves the question of the quantity of foods, and the quality of foods, after one has got his appetite trained, his natural instinct trained; and when it comes to certain diseases like acidity of the stomach, hyper-acidity or hypo-acidity, dilation of the stomach or cirrhosis of the liver, or any other trouble with the digestive organs, if it does not effect a radical cure it makes it possible to tolerate a condition which otherwise would be deadly in a short time. It makes it possible for a patient to live a long time, enjoying comfortable health, where otherwise he would be crippled so that he could not live long at all."

Although we insist upon the fact that Fletcherism is simple, and easy, too, once you have really begun its proper use, yet we also know that there are many difficulties which the average man or woman has to face at the outset. Professor Fisher encountered these difficulties when experimenting with his students at Yale, and we are indebted to him for enumerating some of them. And these difficulties, like the habit of hasty eating itself, are products of our civilization.

We mean such difficulties as, first, _conventionality_, or the desire to eat what others eat, and the unwillingness to appear different; _politeness_, the desire to please one's host, or hostess, and eat "what's set before you," or to eat something which you know you don't want or which you know is bad for you, because you fear to offend somebody or other who has cooked it, or bought it for you; _food notions_, or the opinion that certain foods are "wholesome," and that certain foods should be avoided as injurious even if delicious to the taste; _narrowness of choice_, as at a boarding house table (and a great number of home tables!) which often supplies what is not wanted and withholds what is; and, lastly, habit, by which the particular kinds and amounts of food which have become customary through the action and interaction of the causes previously named, are repeated day after day, without thought.

"Habit hunger" is another of our handicaps. Habit hunger is said by Mr. Fletcher to be responsible for a vast deal of overeating. He refers to the fact that when we are children we eat at least one-third more proteid or tissue-building foods, in proportion to our size, than we require as adults, for the reason that our growing frames must then be nourished and upbuilt; but when we reach the adult stage we are apt to maintain this excessive consumption of proteid food—and proteid, as we shall see later on, is the chief source of dietary ills.

These are some of the difficulties to be encountered by the person who sets out upon the road to health. But they are very slight barriers, indeed, to the person possessed of willpower, and when the benefits and pleasures to be gained are so enormously in excess of the few initiatory troubles, it is not to be wondered at that more than a million persons in England and America are already following Horace Fletcher's system in whole or in part.

HOW CHEWING STIMULATES DIGESTION

Certain remarkable experiments conducted by Rogers, Metchnikoff, and Pawlow in Europe, and by Cannon and Kellogg in America, have thrown a new and interesting light upon the ideas of Fletcher; proving that the act of chewing the food gives to the nerves that control the digestive fluids an opportunity to assay the food, to test it and select for it the particular kind of digestive fluid which that particular kind of food requires. It appears that there are many different kinds of saliva, and each one of these kinds has a particular kind of work to do, which no other kind is able to do. Metchnikoff has shown that if one takes cane sugar into the mouth with or without other food, there is manufactured by the salivary glands a certain peculiar fluid which digests cane sugar. If the cane sugar is not taken into the mouth, then that substance is not made. The saliva that flows into the mouth when there is food there but no cane sugar with the food, will not digest cane sugar. So it readily can be seen that if cane sugar should be hastily swallowed, it is much less likely to be properly digested. And this holds good with nearly all other kinds of food.

THE “FOOD FILTER”

“But how is a person to know when he has chewed a mouthful long enough?” the reader asks. Mr. Fletcher answers that nature has provided us with a food filter—an automatic safety device. Professor Hubert Higgins, formerly demonstrator of anatomy at Cambridge University in England, and Professor Hasheby of Brussels, Belgium, have lately conducted a series of experiments which throw light on this question on its scientific side. At the back of the tongue there are a number of little knobs, which are really taste buds, or apparatus for the tasting of food. During the time that mastication is going on, the mouth is closed and is completely air tight, and germproof. This fact one can readily demonstrate by filling out the lips with air. The mouth is full of air, yet one can breathe behind this curtain of air, showing that the mouth is thoroughly cut off. This is what happens during mastication, for of course one should masticate with the lips closed. Now, when the food has become sufficiently ensalivated, or mixed up, the circumvallate papillæ at the back of the throat, where the taste buds are, relax, and behind that the soft palate forms a negative pressure. This soft palate is muscled just as it is in the horse—which is an animal that masticates, but is not found in the dog, which is an animal that bolts its food. Whenever the food is ready for the body, the soft palate relaxes, and is sucked back, and the swallowing of a mouthful of the prepared food takes place involuntarily.

The body is thus supplied with as perfect a protection as could be devised, and perfectly automatic; all that is necessary being that one should masticate the food until it naturally disappears. One must not attempt to keep the food too long in the mouth, but let it have its own course. There are some sorts of food which, when one has chewed them three or four times, are sucked up, showing that they have received all the mouth treatment that nature requires they should. With other foods one can masticate up to one hundred and fifty times, and still they are not sucked up.

This food filter is a perfectly instinctive apparatus; but as people have acquired the habit of flavoring foods with artificial sauces and relishes, most of them have spoiled this protective device. In the words of Mr. Fletcher himself: “This is a gift of Nature to man which we have been neglecting. It is not a gift which has been given to me and a few others alone. I think everybody could acquire the use of it if they would give Nature a chance by eating slowly, by eating with a sense of enjoyment, and by never eating save when they are really hungry and in a mood to enjoy the food.”

III

THE YALE EXPERIMENTS

At Yale University, Professor Russell H. Chittenden, Director of the Sheffield Scientific School, Lafayette B. Mendel, Professor of Physiological Chemistry, and Irving Fisher, Professor of Political Economy, have carried on a long series of experiments, begun six years ago as a test of the claims made by Fletcher. The net results of these experiments up to date (for they are still in progress) may be put into a nutshell. The following statement was drawn up by one of the writers of this book and submitted to Professors Chittenden and Fisher, who have accepted it as a summary of their present views:

“The commonly accepted standards which claim to tell the quantity of food needed each day by the average man are based upon many careful observations of what men actually do eat.

“We challenge these standards, however, as the exact science of to-day cannot accept as authority common customs and habits in any attempt to ascertain the right principles of man’s nutrition, since experiments have demonstrated how readily one set of habits may be substituted for another and how easily wrong habits become hardened into laws. The evidence presented by observers of common customs, while they must be duly considered, cannot, therefore, be taken as proof that these habits and customs are in

accord with the true physiological needs of the body.

“We believe that the following propositions have been demonstrated as truths by the experiments we have made at Yale.

“People in general eat and drink too much.

“Especially do they eat too much meat, fish and eggs.

“This is so because meat, fish and eggs are the principal proteid-containing foodstuffs.

[Illustration: PROF. RUSSELL H. CHITTENDEN, PH.D., LL.D., SC.D., Director Sheffield Scientific School, Yale University. He has conducted many dietary experiments from the physiologist’s point of view.]

“Proteid is an essential food element, absolutely necessary for the upbuilding of tissue, for the maintenance of life. It is one of three main elements into which all foodstuffs may be divided—the others being Carbohydrates (the sugars and starches) and Fat. While it is indispensable, it is also the element which the body machinery finds most difficult to dispose of. Proteid is ‘nitrogenous.’ Nitrogen is never wholly consumed in the body furnace as fats, sugars and starches are. There is always solid matter left unconsumed, like clinkers in a furnace; which clinkers the kidneys and liver have to labor to dispose of. If the clinkers are produced in excess of the ability of these organs to handle them without undue wear and tear, damage of a serious, and sometimes permanent, nature follows. The ideal amount of proteid is the amount which will give the body all of that substance which it needs without entailing excessive work upon the body machinery.

“Excessive consumption of proteid foodstuffs—like meat, fish and eggs—is the greatest evil affecting man’s nutrition. The excess of proteid not only remains unburned in the bodily furnace, but this waste matter very often decays in the body, forming a culture bed for germs which effect the whole system, a condition scientifically known as autointoxication, or self-poisoning of the body through the action of the germs of putrefaction, and of other germs, which are bred in the colon, or large intestine. The researches of Metchnikoff, Bouchard, Tissier, Combe, and other eminent scientists, have shown that autointoxication is the source of a great number of the most serious chronic diseases which afflict mankind.

“We say, then, that the existing dietary standards place in all cases the minimum of proteid necessary for the average man’s daily consumption at far too high a figure. It may be safely said that it is placed twice as high as careful and repeated experiments show to be really necessary.

“There can be little doubt that the habit of excessive eating and drinking, combined with the habit of too hasty eating and drinking, especially of meat, fish and eggs, are probably the most prolific sources of many bodily disabilities affecting men and women, and are consequently the greatest deterrents to the attaining by men and women of a high grade of efficiency in work, of better health, of greater happiness, and of longer life.

“We believe that it has been demonstrated as a fact that health can be bettered, endurance increased, and life lengthened, by cutting down the commonly accepted standards of how much meat, eggs, fish and other proteid food we should eat and drink by about one-half.”

* * * * *

After Horace Fletcher had attracted the notice of the scientific world in 1902, Professor Chittenden invited him to become the subject of a series of experiments at Yale, where the Sheffield Scientific School possessed an equipment suitable for an elaborate inquiry of this kind much superior to any to be found in Europe.

FLETCHER’S CLAIMS SUPPORTED

Professor Chittenden first made certain, by experiments which precluded any chance of error, that Horace Fletcher’s claims were justified so far as Horace Fletcher himself was concerned. But this, of course, by no means solved the problem. Mr. Fletcher might simply be a physiological curiosity—a digestive freak—of whom there are many known cases. He lived and thrived on an amount of proteid food startlingly less than was deemed necessary by all existing standards, but this could not be taken as proof that people in general could do likewise. Only an exhaustive series of tests on a large number of people of varying ages and conditions of life could prove this. Professor Chittenden resolved to make these tests.

At the very outset, however, he faced this difficulty. If Mr. Fletcher's was merely a freak case, there would be a grave danger in putting other men upon his dietary. Mr. Fletcher was flourishing on a daily consumption of proteid foodstuffs amounting to an average of only 45 grams, and the fat, sugar and starch consumed by him were in quantities only sufficient to bring the total food value of the daily food up to a little more than 1600 "calories," or units of fuel energy. The Voit standard—which is the typical one, the one most commonly accepted, and which is based upon thousands of studies of what men and women actually eat—demands that the average man shall eat at least 118 grams of proteid, with a total fuel value of 3000 large "calories" for the daily ration.

To make clear to the non-scientific reader just what quantity of foodstuffs is represented by 50 grams of proteid, which is 5 grams more than that consumed daily by Mr. Fletcher in his tests, and is approximately the amount consumed daily by other men in the Yale experiments, it may be said that 50 grams is about equal to 772 grains, which are equal to about 1¾ ounces. This quantity would be represented by the proteid contents of 9½ ounces of lean meat, or 7 eggs, or 27 ounces of white bread. Nine and one-half ounces of meat (using comparisons furnished by Dr. Edward Curtis) is about the weight of a slice measuring 7 by 3 inches and cut ¼ of an inch thick. Twenty-seven ounces of bread represent somewhat less than two loaves, the standard loaf weighing one pound (16 ounces). Of course, few people ever eat 7 eggs, or 2 loaves of bread in a day; but the vast majority of people in America do eat a great deal more proteid than would be represented by 7 eggs, or 2 loaves of bread or a slice of meat of the size named, since proteid is found in a great number of other foodstuffs besides those mentioned.

CHITTENDEN'S EXPERIMENTS ON HIMSELF

Professor Chittenden realized that to ask a number of men to subsist on a ration similar to that which nourished Mr. Fletcher might possibly result in seriously weakening their constitutions. This is the problem which has often confronted other scientists, and Professor Chittenden solved it in a way characteristic of the true scientist—the devoted warrior in humanity's cause who wages warfare against the forces of evil. He began his experiments upon himself.

The result rewarded his self-sacrificing spirit; for within a few months a severe case of muscular rheumatism (which had plagued him for years, refusing to yield to treatment) disappeared; and with it went a recurrent bilious headache. And it may be stated that these have never returned. Professor Chittenden has adopted as a habit of life the dietary which he began as an experiment five years ago. At that time he was a hearty eater of three meals a day, meals rich in meat and other proteid foodstuffs.

THE OTHER CHITTENDEN TESTS

Professor Chittenden then began experiments with a group of university professors and instructors, with a group of thirteen enlisted men of the army, and a group of eight college athletes in training. All three of these groups of men were subjected to careful laboratory observations for continuous periods of many months, during which the proteid ration was reduced from one-half to one-third what had been customary. The professors and athletes followed their customary vocations during the period of observations, while to the ordinary drills of the soldiers were added severe gymnasium work under the supervision of Dr. Anderson.

Results were as follows: The subjects usually lost some weight, especially such as were fat. But it was found that having got down to a new standard, they held this steadily. They all maintained muscular and nervous vigor. Careful tests determined that the soldiers and athletes positively gained in muscular strength. All kept in good health; and many got rid of illnesses with which they had been suffering in the beginning. Appetite was thoroughly satisfied; and quite a number of the subjects permanently adopted the new method of living. Nine of the soldiers went in a body to a new station, and from thence they afterwards wrote, through one of their number, to Professor Chittenden, saying: "The men are in first-class condition as regards their physical condition, and all of them feeling well. We eat little meat now as a rule and would willingly go on another test."

At the beginning of the experiments these soldiers were subsisting on a daily ration which allows one and one-quarter pounds of meat per day apiece; and toward the end of the experiments they were subsisting and increasing their strength on a daily ration of meat equivalent to about one small chop or less!

These experiments constituted the first series made by Professor Chittenden. He later carried through a series with dogs: prior experiments having supported the view that the dog, a typical high proteid-consuming animal, declined or died when forced to subsist on quantities of proteid less than the amount ordinarily consumed. Professor Chittenden, however, challenged here the methods, as well as the results, of previous investigators. In previous experiments with dogs the animals had been invariably handicapped by being confined in dark and dismal quarters, too cramped to permit of exercise, and at times unsanitary in condition. He reversed these conditions—and reversed the results. His dogs lived and thrived on a diet far less rich in proteid than former

investigators deemed necessary.

PROFESSOR CHITTENDEN'S CONCLUSIONS

Summing up the conclusions reached by him after arduous years of experiment and study, Professor Chittenden declares that 60 grams of proteid (about the quantity which a single small chop would supply) are all that are required by the average man of 150 pounds body weight. This is one-half the Voit standard, and far below the common practices of the majority of mankind in Europe and America.

"But there should be no practical use of the terms 'standard diets' and 'normal diets' by people in general," says Professor Chittenden. "What is needed to-day is not so much an acceptance of the view that man needs so many grams of proteid per kilogram of body weight, as a full appreciation of the general principle that the requirements of the body for proteid food are far less than the common customs of mankind, and that there are both economy and gain in following this principle in practice."

HOW TO INCREASE ENDURANCE

The most broadly interesting of these Yale food experiments are those having to do with the question of endurance. The vast majority of people are not ambitious to excel as athletes; they find better and more enjoyable forms of work in life than putting up big dumb-bells, or breaking records on the athletic field. Of course, everybody wants to be strong, and to have well-trained and active muscles; but on the whole, what the majority of people need is physical and mental stick-to-itiveness—the ability to work without deterioration, without running down like worn-out machinery. Professional men, day laborers, students and athletes, all need this invaluable quality of endurance—this quality that is the true capital in the bank of life to be at their command day in and day out, with a reserve ready to be drawn upon whenever an emergency arises. And it is precisely here that the new art of health bestows its benefits upon those who follow it.

It was to ascertain the relation between diet and endurance in the light of the new knowledge shed upon the subject by Professor Chittenden's experiments, that Professor Irving Fisher inaugurated his own experiments at Yale University. He conducted two series of tests, as follows:

First, to ascertain the effect of thorough mastication on endurance, following the rules laid down by Horace Fletcher, with the help of nine healthy students.

Second, to ascertain the influence of flesh eating on endurance as compared with the effect of abstinence from flesh, with a group of forty-nine persons, splitting the group as follows,—first, athletes accustomed to a flesh, or high proteid dietary; second, athletes accustomed to a low proteid, or non-flesh dietary; third, sedentary persons accustomed to a low proteid, or non-flesh dietary.

[Illustration: PROF. IRVING FISHER, PH.D., Professor of Economics at Yale University. His investigations have had to do largely with the cost of necessary food.]

The flesh-eaters were Yale men, including some of the best known athletes of the university. The abstainers were nurses and physicians attached to the Battle Creek Sanitarium.

Professor Fisher's interest in the subject was that of a political economist. Meats, as a general rule, are the most expensive part of the national diet, and it is apparent that if a fleshless, or low proteid, diet will increase endurance, it will also increase the national earning capacity, and thus add to the national wealth. When Professor Fisher began his experiments he encountered a singular fact, which was that the science of physiology had given very little attention to the study of endurance. "That strength and endurance are not identical, is only partly recognized," he writes. "The strength of the muscle is measured by the utmost force that it can exert once; its endurance, by the number of times it can repeat any exertion within its strength. The repetition of such exertion, if not stopped by the refusal of the will, is finally stopped by the reduction of the strength of the muscle till it is unable to perform further. Thus endurance may be expressed in terms of loss of strength. It is related to fatigue, and it is only through the study of fatigue and fatigue poisons, made by Mosso and others, that light has been thrown on the nature of endurance."

When these tests were held Professor Fisher had not then invented the machine for registering endurance which is now in use in the Yale gymnasium; therefore, three simple tests were employed: first, holding the arms horizontal as long as possible; second, deep knee bending; third, leg raising with the subject lying on his back.

VICTORY FOR THE LOW PROTEID DIET

The results of the competitive tests were all in favor of the flesh-abstaining athletes. In the first test, which was holding the arms horizontal, only two of the fifteen flesh-eaters succeeded in holding their arms out over a quarter of an hour; whereas twenty-two of the thirty-two abstainers surpassed that limit. None of the flesh-eaters reached half an hour, but fifteen of the thirty-two abstainers exceeded that limit. Of these, nine exceeded one hour, four exceeded two hours, and one exceeded three hours, the last going exactly two hundred minutes, or three hours and twenty minutes.

In the leg raising test the record showed little difference. None of the abstainers reached their absolute limits. The highest record for the abstainers was one thousand times. A flesh-eater reached one thousand, three hundred and two, but did so after the one-thousand mark had already been set for him by an abstainer, and he went into the test with the expressed intention of defeating his rival. Professor Fisher states that it was evident from his fatigue at the end of the test that he could not have repeated the performance on the next day, as did his flesh-abstaining rival.

In respect to deep-knee bending, Professor Fisher pointed out that of the nine flesh-eaters who went into this contest, only three went above three hundred and twenty-five times, while of the abstainers, seventeen surpassed this figure. Only nine of the flesh-eaters reached one thousand, as against six of the twenty-two abstainers. None of the flesh-eaters surpassed two thousand, while two of the abstainers did. One abstainer, an athlete, S. A. Oberg, did two thousand and four hundred dips or deep knee bends, almost doubling the highest figure set by the flesh-eating athlete, which was one thousand, two hundred and ninety-two. Most of the Yale flesh-eating athletes were so severely crippled by their efforts in this particular set of movements that Professor Fisher resolved not to employ them again, and went to work on his device for mechanically registering endurance. One of the Yale athletes, who in the deep-knee bending test had reached five hundred times, fainted. Several had to be carried down the gymnasium stairs, and others were made so stiff and sore that for days they could not walk up and down stairs with comfort, while in the case of the abstainers from flesh foods there were comparatively little painful after-effects. Two of the abstainers, one a Yale athlete, were almost free from physical after-effects. The Yale man ran on the track of the gymnasium after his performance, and took a long walk afterward; while the other athlete, Oberg, a Sanitarium nurse, who made the highest record of all, two thousand four hundred times, continued his duties and found little annoyance from stiffness or soreness. (Another flesh-abstaining athlete, John E. Granger, of Battle Creek Sanitarium, has since made a new record of five thousand and two dips in two hours and nineteen minutes.)

Professor Fisher tried many means to stimulate the flesh-eating athletes to do their very best. He called upon their “Yale spirit” to rally to their aid, and he states that the advantage of rivalry as between the flesh-eaters and the abstainers was decidedly upon the side of the flesh-eaters, for their tests, with two exceptions, came after all the records of the abstainers had been completed. The Yale men felt that their tests would go on record as tests of Yale athletes, and Professor Fisher states that the “Yale spirit” which aided them appeared to be as great a stimulus as any “vegetarian” spirit could possibly be.

THE RESULT OF THE MASTICATION TEST

As to the experiment with the nine healthy students, Professor Fisher says:

“The results of the experiment demonstrated so great an increase of endurance as to seem at first incredible. It certainly was a surprise, both to the men and to me. But statistics which I have been collecting during the last two years have prepared me to find great differences and changes in endurance. The special result of the present experiment is to show that diet is an important factor in producing such alterations. The fact that endurance, even among persons free from disease, is one of the most variable of human faculties—far more variable than strength, for instance—is evident to any one who has made even a superficial examination. Some persons are tired by climbing a flight of stairs, whereas the Swiss guides, throughout the summer season, day after day spend their entire time in climbing the Matterhorn and other peaks; some persons are “winded” by running a block for a street car, whereas a Chinese coolie will run for hours on end; in mental work, some persons are unable to apply themselves more than an hour at a time, whereas others, like Humboldt, can work almost continuously through eighteen hours of the day.

[Illustration: MR. JOHN E. GRANGER BREAKING THE WORLD’S RECORD FOR DEEP KNEE BENDING. The spectator at the extreme right is Mr. Alonzo A. Stagg, coach of the Chicago University football team. Mr. Michael Williams is between the two.]

“It is, to say the least, remarkable that hitherto so little effort has been directed toward discovering the factors which explain such differences in endurance. That exercise is one of the most and perhaps the most important factor has long been recognized. A correspondent assures me that by means of moderate _regular_ exercise he succeeded in increasing his endurance between 100

and 200% in three weeks as measured by leg-raising and “dipping.” The influence of diet has always been regarded as small or negligible, and the opinion has almost been universal, until recently, that a diet rich in proteid promotes endurance. Even among those whose researches have led them to the opposite conclusion, there is very little conception of the extent to which diet is correlated with endurance. Such a person, a medical friend of the writer, stated, when the present experiment was planned, that he did not think the dietetic factor strong enough compared with others to produce any marked effect. We have all heard, of course, of the enthusiastic reports of vegetarians as to their increased endurance, but these we have discounted as exaggerations. The result of the present experiment, however, would seem to indicate that one’s improvement in endurance is usually not less, but greater, than he himself is aware of. Probably it is also true that we may lose a large fraction of our working power before we are distinctly conscious of the fact.

“While the results of the present experiment lean toward ‘vegetarianism,’ they are only incidentally related to that propaganda. Meat was by no means excluded; on the contrary, the subjects were urged to eat it if their appetite distinctly preferred it to other foods.

“The sudden and complete exclusion of meat is not always desirable, unless more skill and knowledge in food matters are employed than most persons possess. On the contrary, disaster has repeatedly overtaken many who have made this attempt. Pawlow has shown that meat is one of the most, and perhaps the most, ‘peptogenic’ of foods. Whether the stimulus it gives to the stomach is natural, or in the nature of an improper goad or whip, certain it is that stomachs which are accustomed to this daily whip have failed, for a time at least, to act when it was withdrawn.

“Nor is it necessary that meat should be permanently abjured, even when it ceases to become a daily necessity. The safer course, at least, is to indulge the craving whenever one is ‘meat hungry,’ even if, as in many cases, this be not oftener than once in several months. The rule of selection employed in the experiment was merely to _give the benefit of the doubt_ to the non-flesh food; but even a _slight_ preference for flesh foods was to be followed.

“Under flesh foods are included all meat and ‘stock’ soups. It has been shown that although these extracts of meat contain a large amount of nitrogen, it is not in the form of proteid which can be utilized, but only of waste nitrogen which must be excreted. Apparently the sole virtue of such soups is that they supply the ‘peptogenic’ stimulus above referred to.

ANYBODY CAN APPLY THE NEW KNOWLEDGE

“The practical value of the experiment consists in the fact that any layman can apply it, with or without a knowledge of food values, though with more advantage if he possess than if he lack such knowledge. If the dietetic rules of the present experiment are followed, no self-denial as to foods is required. It is, however, absolutely necessary that there should be _self-control_ enough to break up the habit of hurried eating to which modern civilization has brought us—habituating us, as it were, to eat against time.

“Experience indicates that appetite does not lead to a diet fixed in amount or constituents, but moves in undulating waves or cycles. The men who took part in the experiment were encouraged, after any of the symptoms which seemed to be associated with high proteid (such as heaviness, sleepiness, stiffness, or soreness after exercise, or catching cold), to cut down on their proteid and substitute fat to restrain the gastric juice. This advice was intended to make application of the theories of Folin that we usually carry a reservoir of proteid, enough to supply our needs for body-building for a fortnight. If this reservoir is exhausted, proteid starvation occurs and the body feeds on itself; if it is filled too far it overflows and causes the evils of excessive proteid. If this theory is correct, the art of eating may consist largely in maintaining a golden mean, such that the proteid reservoir is neither empty nor overflowing much. Many persons fear to reduce their proteid to the Chittenden minimum for fear of proteid starvation; but the experience of those who have tried it would seem to show that this fear is groundless, _provided_ no violence is done to natural appetite. This may be trusted, so it would appear, to raise a warning in the form of ‘nitrogen hunger,’ before the danger point is reached.” In other words, the body will ask in the language of hunger for proteid food, if you are not eating as much as you should. Professor Fisher considers that an amount of meat equivalent to about one small chop will supply all the proteid necessary in the daily ration, since proteid is also consumed in bread, potatoes and nearly all other foods.

It might be added that one of the writers has found the remedy for continual bilious headaches in the rigid exclusion from his diet of all foods that are rich in proteids, including meat, fish, eggs, milk, cheese, peas and beans; and maintains weight and working efficiency upon such amount of proteid as he derives from ordinary breadstuffs. He has found that the craving for high proteid foods soon disappears if it is not gratified; and that the quantity of bread, potatoes, etc., which the average person would eat at dinner and supper supplies all the nitrogen which his system needs, without leaving any to cause autointoxication.

IV

HOW DIGESTION IS ACCOMPLISHED

In order not to interrupt the narrative of the Yale experiments, we have foregone defining certain of the technical terms which it was necessary to use. It will be well, before going further, to give a simple description of the manner in which the food we eat is transformed in the body into tissue building material and energy: a process the many parts of which are grouped by physiologists under the name of Metabolism.

When you take a mouthful of food it enters on a journey through the body in which it traverses more than thirty feet of the intestinal tube before that part of it which the body cannot use is ejected; the process of metabolism begins the moment the lips touch it. The six salivary glands which are located in the mouth manufacture saliva, which flows out through numerous openings, and mixes with food as it is chewed. The saliva not only moistens the food, thus allowing it to be more easily swallowed, but it also has a most important chemical office, converting all starchy food matter into sugar, and thus performing the first and one of the most essential steps in the process of digestion.

After the food has been masticated and saturated with saliva, it passes down the throat through the gullet, which performs a peculiar muscular contraction, thrusting downward the particles of food. The conversion of the starch in food into sugar, or glucose, which is begun by the saliva in the mouth, is continued as the food passes into and down the gullet, but stops almost completely when the food once reaches the stomach.

THE WORK OF THE STOMACH

It is in the stomach, on the other hand, that most of the work of digesting the albuminoids, or proteids, of food is performed by the gastric juice. The stomach is a pear-shaped bag, that holds about three pints of material, or three-quarters of an ounce for every inch of the individual's height. Food enters it through the gullet on the upper left hand side, just below the heart. Myriads of glands in the walls of the stomach are active in the formation of either pepsin, or an acid fluid which, when combined with pepsin, forms the gastric juice.

At the back of the stomach, partly overlapping it, lies the liver, which discharges a liquid called the bile into the alimentary canal just below the stomach. Behind the stomach, lies a large gland called the pancreas, which discharges a remarkable fluid, named pancreatic juice, into the intestine through the same opening which the liver uses for its bile. Connected with the stomach is the small intestine, which is the narrow portion of the alimentary canal, and the largest and most important of all the digestive organs. It is some twenty-five feet in length, and its walls are everywhere covered with glands which secrete and exude mucous and other fluids.

At the lower end of the intestine is the colon or large intestine which is not a digestive organ in itself, but is a reservoir in which the food is stored up for a short time, to allow opportunity for complete absorption of the digested portions.

THE ELEMENTS OF FOOD

Although there may be thousands of different dishes, and combinations of foodstuffs, fundamentally they are all closely akin, and can be all resolved into a few quite simple elements: Proteid, Carbohydrate, Fat or Mineral Salts, or combinations of these; the Proteid class having many subdivisions, and the Carbohydrates being made up of the various sugars and starches.

We also know definitely just what use the body makes of these various substances. The Proteid is the up-builder of tissue, the essential foodstuff without which life cannot exist. If we compare the human body to an engine, as nearly all physiologists seem bound to do, we may say that Proteid is like the brass, or other metal, of which the structure is composed. The various Carbohydrates and the Fats are the fuels from which are derived the energy which animates and operates the mechanism. The Mineral Salts are used to supply various important bodily needs, such as elements required by the bones, or the delicate tissue in the eyes, the enamel for the teeth, and so forth.

THE WORK OF THE DIGESTIVE JUICES

As there are five main food elements, namely, proteid, starch, sugars, fats, and salts, so also there are five main digestive fluids, the saliva, the gastric juice, the bile, the pancreatic juice, and the intestinal juice.

The saliva is an alkaline fluid that digests starch. Its work is checked by the presence of acid substances; which explains why the digestive action of saliva ceases soon after it enters the stomach. Hence the importance of giving the saliva ample opportunity to perform its function, by complete mastication, is obvious.

The gastric juice, of which about seventy ounces is formed by the stomach daily, contains in addition to hydrochloric acid, a quantity of pepsin, which with the acid dissolves all sorts of proteids or albuminous substances, like meat and eggs; and it also contains rennet, which coagulates milk. The gastric juice digests proteids by converting them into pepsin, an exceedingly soluble substance which passes readily into the blood.

The bile manufactured by the liver has the function of digesting fats. Fats are not changed chemically, as are starches and proteids. They are only broken up into particles so small that the cells of the mucous membrane can take them up and effect their removal into the blood stream.

The pancreatic juice is able to perform the work of all the three digestive fluids which we have already named. In fact, it is even more powerful than saliva in the digestion of starch, since it is able to digest raw as well as cooked starch, which the saliva cannot do. It is also able to convert proteid into peptone, as does the gastric juice; and it emulsifies fats, as does the bile.

The intestinal juice digests cane sugar, and is supposed to have a digestive influence upon all the other food elements.

The mineral salts which are taken into the body are dissolved by all the digestive fluids which we have named, some by the saliva and the juices of the intestinal tube, and others, which require acids for their solution, by the gastric juice.

Nearly all these digestive fluids are also powerful antiseptics and are able to destroy germs when the health of the body as a whole is good. The gastric juice, for instance, acts as an antiseptic, preserving the stomach contents from putrefaction during the digestive process. It is a remarkable fact that the gastric juice, although it is so essential to life, is a deadly poison, which, when introduced into the blood produces insensibility and death.

These digestive juices and organs are able completely to dispose of all the food elements which are introduced into the body, save proteid alone. The sugars and starches are either completely absorbed and oxidized, or stored up in the form of surplus fat. The oxidation or burning up of proteid, however, is never complete. There is always a certain amount of unburnable substance left behind from the processes of metabolism, which the liver and kidneys of the body have to dispose of. If only as much proteid as is needed by the body for the upbuilding of its tissue, and the repair of waste, is taken, the body can very readily handle it; but an excess of proteid is highly disadvantageous. Professor Chittenden, in his great work, “The Nutrition of Man,” has set forth in elaborate detail the process of the assimilation of proteid. It appears that there are many kinds of proteid; the proteid of eggs is different from that of meat, and that again from the proteid of beans, and so on; and human proteid is different from all. Consequently, the body is obliged to transform every kind of proteid which is brought to it. This proteid is then absorbed by the blood, and carried to the tissues, which are kept perpetually bathed in a supply of nutritive material. The taking of more proteid than is needed would not be so dangerous if it were simply passed on without being digested; nor even if it were digested and transformed, and then promptly eliminated. But what actually happens is that the new proteid taken in is passed through all the stages of assimilation, and drives out in front of it, so to speak, the proteid which has already been prepared, but has not yet been used. And the result is, of course, to throw a double strain upon the liver and the kidneys, the organs of elimination.

Professor Chittenden also points out the common blunder which is made in assuming that persons who are doing hard work need an additional amount of proteid substance. One commonly hears the phrase that laborers and athletes can eat meat in large quantities, and “work it off.” As we have seen, one can “work off” sugars and starches and fats completely; but one cannot “work off” proteid completely. Professor Chittenden is now recognized as the leading authority of the world upon this particular question; and he sets forth clearly in his book the fact that the quantity of proteid needed is not increased by muscular activity. One may work as hard as he pleases, but his body will use no more nitrogen, save only in the case where a sufficiency of other food elements is not supplied. Only as a last resort will the system undertake the labor of burning up proteid to make energy.

HOW MUCH SHOULD WE EAT

When foodstuffs are taken into the body, digested, assimilated, and used up, they produce the same amount of heat and other forms of energy as if burned outside of the body; and hence it follows that the number of calories, or units of heat, represented in a given foodstuff, is taken by scientists as a common measure of its food value.

A calory is a heat unit, which has been adopted as a means of estimating the nutritive value of foodstuffs. It represents the amount of energy required to raise the temperature of four pounds of water one degree Fahrenheit. The number of calories contained in food is obtained by burning the food and measuring the heat produced by means of a calorimeter.

It has been calculated that the normal, average person needs from one hundred and sixty to two hundred and forty calories of proteids every day, in order to build blood and tissues. He needs daily from five hundred to nine hundred calories of fats, which supply heat.

He needs of carbohydrates, which are the starches and sugars, and which the body uses to produce energy for work and heat, from one thousand to one thousand four hundred calories daily. It is declared by Chittenden and Kellogg, whose work has overset the old notions, that the total number of calories, or food units, should rarely exceed two thousand.

Two thousand calories are furnished respectively by twenty-eight ounces of bread, or ninety-six ounces of milk, or sixty-two ounces of potatoes, or nine ounces of butter. One quarter of each of these, or any other fractions which together equal unity, will make up a ration containing two thousand calories.

It is quite impossible, however, to make a hard and fast rule in this matter. Every individual differs from others in his requirements. Moreover, the weather, the season of the year, the amount and kind of work done, are all factors in the situation. Hard physical work and exposure to cold demands the largest food supply. A person who naturally perspires freely needs more food than a person who does not, because of the large amount of heat carried off from his body by the evaporation of sweat from the skin. Adults require food chiefly to repair waste and losses. Growing children require in addition to food to repair waste and losses, material for tissue building. According to the best authorities upon the diet of children, a growing infant utilizes fully one-third of its total intake of food in tissue building. When an adult becomes emaciated he requires more tissue building material than the normal adult, his need for it being practically the same as that of a growing child.

We give below a table showing the average number of food units or calories required daily by people of various heights and weights. This table is one drawn up by Dr. J. H. Kellogg, Superintendent of the Battle Creek Sanitarium. In calculating the number of calories required in a given case, the estimate should be based not upon the actual weight of the individual, but upon the weight of the average person of his height.

“Persons who are in good health,” says Dr. Kellogg, “and find their weight somewhat greater than the figures given in the table, should not necessarily consider themselves obese. While above the average in weight, their condition is probably natural, and no attempt should be made to reduce the weight to any considerable amount, as injury may result. The average for adults applies especially to healthy adults between twenty and thirty years of age. Most people who are above forty years of age have a natural tendency to increase of flesh, which requires no attention unless it becomes excessive. Any reduction in foods made by an obese person should be in carbohydrates rather than in proteids or fats, unless these latter have been taken in excess.”

TABLE NO. 1

Showing for different ages the average height, weight, and the number of food units or calories required daily.

Boys

Height in Weight in Calories or Age Inches Pounds Food Units 5 41.57 41.09 816.2 7 45.74 49.07 912.4 9 49.69 59.23 1,043.7 11 53.33 70.18 1,178.2 13 57.21 84.85 1,352.6

PRACTICAL APPLICATION OF DIETARY RULES

While dieticians have ascertained the number of food units daily required by the average person, yet on no point do they reach more thorough agreement than in saying that the average person should not establish any hard and fast rules as to the quantity and kinds of food he consumes. It is really only an invalid, one who is in a physician's care, who needs to have his food regulated in this precise fashion. The average person should be careful to practice thorough mastication, and should see to it that the proteid part of his meals is not excessive, but he should avoid worrying about his food habits. Any person who fusses and fumes about the kind of foodstuffs and the number of calories they contain, will be apt to cause himself harm; for science has proved by laboratory experiments, which we shall describe later on, that worry, in fact any of the unpleasant emotions, exercises a prohibitive effect upon the flow of digestive juices.

The really important thing to do is to follow a simple dietary, which at the same time is well balanced in its food elements, well cooked, and tastefully served. The housewife will see to it that the foodstuffs she chooses represent more of carbohydrates and fats than of proteids; her guiding rule in this matter being that _the proportion of proteids to the other food elements be ten per cent._ The United States Department of Agriculture has prepared a list of foodstuffs, comprising all those in common use, which shows the proportion of their constituents, and their total energy value, in calories, per pound of material.

This is "Bulletin No. 28, Revised Edition," the work of two of the leading physiological chemists of America, W. O. Atwater and A. P. Bryant; and may be had on sending five cents to the Department. We have inserted in the Appendix a selected list of foodstuffs taken from this publication; and we give here a rough classification of foods, from which one can see at a glance their leading elements:

FOODSTUFFS WHICH ARE RICH IN PROTEIDS

Eggs White of Egg Skimmed Milk Buttermilk Yogurt Cottage Cheese Nut Products

FOODSTUFFS WHICH ARE RICH IN FATS

Butter Nut Oils Olive Oil Cream Olives Nuts (except chestnuts) Egg Yolks

FOODSTUFFS WHICH ARE RICH IN CARBOHYDRATES

Potato Rice Breads Cereal Preparations

PURE CARBOHYDRATES

Fruits (raw and cooked) Fruit Juices Fruit Jellies Honey Malt Honey Marmalades

FOODSTUFFS WHICH ARE RICH IN PROTEIDS AND FATS

Nuts Nut Butters Eggs Cheese Nut Products

FOODSTUFFS WHICH ARE RICH IN PROTEIDS AND CARBOHYDRATES

Peas Beans Lentils Chestnuts Skimmed Milk Gluten Preparations.

FOODSTUFFS WHICH CONTAIN ALL THE FOOD ELEMENTS IN FAIRLY GOOD PROPORTION

Crackers Batter Breads Pastry Malted Nuts Custards Puddings Salads Sandwiches Soups (other than meat or fish soups).

V

HOW FOODS POISON THE BODY

In our survey of the processes and organs of digestion, we saw that after food has traversed the stomach and small intestine it passes into the colon, where it must remain for some considerable time, while the absorption of its digested elements is completed. And this brings us to the most important of the discoveries of the new hygiene. It has been found that some of the foods which human beings eat are loaded with injurious bacteria, and with the poisons which these bacteria produce. And others of them are indigestible, and when they reach the colon, become a source of incubation for countless billions of other bacteria. It was demonstrated by Metchnikoff that these poisons are absorbed into the system, and are the cause of manifold evils. This is the process which is called “autointoxication.”

It would not be regarded as an exaggeration by the leading physiologists of the world to-day to speak of autointoxication as the primary source of nine-tenths of the afflictions from which humanity suffers. Any one would be prepared to admit that the banquet he had attended on the previous night was responsible for the headache which he has on the present morning; but the investigations of bacteriologists have revealed that the food habits of which banquets are typical are responsible for a chronic ailment, of which such diseases as gout, rheumatism, Bright’s disease, consumption, and pneumonia are merely symptoms.

THE INVESTIGATIONS OF METCHNIKOFF

Elie Metchnikoff, sub-director of the Pasteur Institute of Paris, is a philosopher, as well as a physiologist; a philosopher who brings to the support of his speculations the exact methods of the laboratory. He, with the other great leaders of the new art of health, is at last removing from science the reproach leveled at it by Metchnikoff’s great fellow-country-man and friend, Tolstoi, who said that science was useless to man, since it did not direct its attention to the problems which mean most to humanity, such as the great questions of life and death, but confined its efforts to investigating useless birds and butterflies.

[Illustration: M. ELIE METCHNIKOFF, OF THE PASTEUR INSTITUTE OF PARIS. His researches have thrown great light on autointoxication. He believes that the normal life should be over 125 years long.]

The books in which Metchnikoff has recorded the results of the investigations which for many years he has been making into the problems of old age and death, have caused a profound sensation in the scientific world. In these books, the great Russian emphatically and definitely ranks himself with the optimists. He states that scientific study of the constitution of man, and of the workings of man’s nature, and of his environment in the world, do not support the view that man is born unto sorrow as the sparks fly upward—to quote the words of the Psalmist—but can really be fitted to live a useful and happy life, ending in a calm and peaceful old age—if man will but turn his attention to the knowledge by which he can really live in harmony with his environment. Metchnikoff has arrived at the conclusions that man and woman would live to be at least one hundred years old, if they could enable their bodies to eliminate those deadly toxins which are the product of the activities of the bacteria which inhabit the human body, as well as of the body’s own organic processes.

Age is not always to be computed in years. As a common saying puts the case, “A man is as old as he feels, a woman as old as she looks.” A famous French physiologist has altered this to read, “A man is as old as his arteries.” The primary change produced by the coming of old age is the hardening and withering of the arteries. As the result of this withering process, a large number of the smaller arteries disappear, so that the blood supply of the muscles, brain, heart, and other important organs, is cut off. This is the change that is technically known as “arterio-sclerosis.” It is quite often found in persons of less than fifty years of age. On the other hand, Harvey, the famous discoverer of the circulation of the blood, declared that in the post-mortem examination made of Old Parr, the celebrated Englishman who died at the age of one hundred and fifty-two years and nine months, he found not a trace of this degenerative change.

In the United States the average length of life is about forty-two years; but a large and growing school of modern scientists (comparative anatomists) declare that the natural age of the human family cannot be much less than from one hundred, to one hundred and twenty-five years. Any death that comes at least before one hundred years, is not a natural death but accidental or violent. From the point of view of science, death through disease is just as accidental and violent as the extinguishment of life in a railway wreck or by drowning in the sea; and the fact that the average life of man is to-day only about one-third of that which nature designed for him is due to the operation of autointoxication more than to any other cause.

Natural death in man is therefore more a possibility than an actual occurrence. Nevertheless, instances have been recorded of the actual appearance of the instinct in aged people, where the wished-for death came not because life was burdensome, not because of poverty, disease, or loneliness, but seemed to arrive as naturally as sleep to a younger person, or the wish for more extended life which all of us possess. Metchnikoff states that instances of veritable cases showing an instinct of death are extremely rare, yet this

instinct really does seem to lie deep in the constitution of man. And if the cycle of human life followed an ideal course, he concluded men and women after living a healthy and useful life extending over at least a century, with their usefulness and satisfaction in life at maximum during the latter portion of that period, would then give themselves up calmly and gracefully to the arms of death, as to the arms of a friend laying them down to earned and wished-for rest. Old age would have no terrors, and death no victory.

It has been, perhaps, Metchnikoff's crowning discovery, that the immediate cause of old age is not merely the accumulation of poisonous wastes, but is due to a destruction of the tiny cells which make up the tissues by certain cells of the body, which he describes as macrophages. These are of an especial kind, which wander through the body and devote their energies to the destruction of waste particles and organic débris—particles of material which are not used in the building up of tissue, just as particles of brick and wood might be left on the ground after the erection of a house. These macrophages enact the part of scavengers, very much like the turkey buzzards, which in southern cities eat up the refuse from the back alleys. Just so long as these wandering cells confine themselves to this useful and necessary work, all goes well; but when the vigor of the body cells has been lowered by the accumulation of tissue poisons, these scavenger cells turn traitor to the cause of the body and attack the very cells which they formerly guarded. They have been photographed in the very act of devouring nerve cells in the brains of old people.

HOW TO PREVENT DEGENERATION OF TISSUE

It can readily be seen that if the pernicious activity of these macrophages can be prevented, the coming on of degenerative changes in the body tissue will be much delayed. The practical question, which Metchnikoff therefore asked himself was, How may this revolt of the macrophages, this rebellion of the body's army, be prevented?

It is not possible to attack the macrophages themselves without at the same time doing damage to the body. For these wandering cells are more hardy and vigorous than the higher cells by which the bodily functions are performed, and which they attack, so whatever might be done to weaken the attack of the wandering cells would to a greater degree damage the higher cells of the body. The conclusion that Metchnikoff reached was that the only direction in which we can hope for success in the attempt to prolong human life, lies in giving attention to the predisposing causes which weaken the vitality of the higher body cells and thus expose them to the successful attacks of the scavenger cells. In other words, if we are to prolong human life, we must make the conditions of life such that the premature accumulation of body wastes or poisons shall be prevented.

One of the first steps to take to affect that end is, obviously, the avoidance of the introduction of poisons, and poison-forming foods, into the body. Out of all proportion to all other causes which lead to the formation of body poisons, is the production of toxins in the colon or large intestine. Metchnikoff's studies show beyond a doubt that there is a close connection between the size of the colon and the duration of life in various birds and animals. Where the colon is used, and has attained large proportions, as in man, in the horse, and many other animals, life is comparatively short, and death is premature. Where the colon is rudimentary, or where only such foods are eaten as do not decay or ferment in the colon, then life is long.

Thus the most important problem, according to Metchnikoff, is how to prevent the development of poisons in the colon. He believes that the colon, indeed, is quite superfluous, and that man would be better off without it. He quotes several curious cases in which the colon has been removed from the body, and the subjects of the operations have recovered impaired health and lived for long periods afterwards. Since the colon cannot be generally removed from the body, however, the practical problem comes down to this: How may we avoid the evils which result from the fermentative and putrefactive processes which go on in this organ?

If the large intestine is kept clean, if only those foods which are antitoxic are eaten, then there will be very few poisons generated in the colon, and the health of the body will be maintained in a higher degree and for a much longer period than can be possible when toxic foods are freely partaken of. It is here that the great argument for vegetarianism on its scientific side arises. All meats and fish are not only "toxic" foods in themselves, but they are quite likely to contain parasites of various kinds.

Ordinary bread has been shown to contain a sufficient amount of proteid to supply all the body needs, as do also rice and other cereals and potatoes. Nuts and dried peas and beans are exceedingly rich in proteid, like meat, and therefore should be eaten sparingly. The best foods in the order of excellence are given by Dr. Kellogg, as follows—the antitoxic foods being in italics: _fresh ripe fruits_, _cooked fresh fruits_, _cooked dried fruits_, nuts, cooked cereals, _rice_, _zweibach_, _toasted corn flakes_, _potato_, _cauliflower_, _and other fresh vegetables_, _honey_, _malted nuts_, _yogurt_, _or buttermilk_, sterilized _milk_, and cream, peas, beans, lentils, _raised bread_, and sterilized butter.

HOW TO ENLIST THE SERVICES OF FRIENDLY GERMS

Since the poisons which are produced in the colon are due to the growth and cultivation of germs, the remedy which naturally suggested itself to a bacteriological specialist like Metchnikoff was to find some harmless or comparatively harmless germ with which the poison-forming germs might be fought—or, in other words, to introduce into the body an extra battalion of soldiers to assist the warrior cells in the battle of the blood.

After years of study and research, Metchnikoff found this beneficient germ in various lactic acid forming microbes, particularly an especial microbe known by the name of Bulgarian bacillus, or Yogurt. This bacillus grows in milk, and in growing it produces large quantities of pure lactic acid. It does not decompose fats, nor does it produce alcohol, as do other lactic forming germs, such as those found in kumyss, matzoon, and kephir.

Milk is first sterilized by boiling for a few minutes, then allowed to cool and a quantity of the ferment is added. In a few hours a sour taste which is pleasant to all whose palates relish mild buttermilk, is developed. Metchnikoff advises that a pint or a pint and a half of this sour milk be taken daily. By this means large quantities of the acid forming and beneficient germs are taken into the intestine, and by degrees the poison producing germs are killed or driven out. Thus the work required of the kidneys, the liver, the skin, and other excretory organs is lessened, and the vigor of the living cells is maintained so that the macrophages do not attack and destroy them.

In Bulgaria where Yogurt is a staple article of food, there are more centenarians, and more vigorous old people to be found than anywhere else on earth. Not only are the Bulgarians and the Hungarians the longest lived races in Europe, but they show a remarkable freedom from appendicitis, colitis, and other diseases due to intestinal infections, circumstances which called the attention of European physicians to a study of the milk ferment which produced Yogurt, and led to the scientific investigations, first by Masson of Geneva and later and more completely by Metchnikoff and Kellogg, which have placed its use both as a curative and a preventive agent upon a thoroughly scientific basis.

Its use is bound to supersede that of kumyss, kephir, matzoon, and other lactic acid ferments on account of the fact that these ferments are able to live only in the small intestine, while Yogurt bacillus thrives in the colon, where it may be found weeks after the administration of Yogurt has ceased. The importance of this fact will be seen at once when it is recalled that the colon is the chief seat of the anaerobic infection and poison production which are the causes of intestinal autointoxication. Thus the last word of modern science on this subject would seem after all to be but the confirmation of a means for reaching natural old age which has been known for hundreds of years. But to-day we are learning to use means for the prolongation of life by the light of knowledge; no longer blunderingly, handicapped by evil habits which nullify the value of the small fraction of hygienic truth which we possess. To-day, Hygeia, while it holds out to our lips an elixir of life, insists that if it is to have its maximum power, we must also breathe rightly, sleep rightly, and eat and drink rightly.

VI

SOME IMPORTANT FOOD FACTS

The importance of avoiding constipation will be obvious to those who have followed this account of the process of autointoxication; one should see that his daily bill of fare contains a generous supply of laxative foodstuffs, such as sweet fruits, ripe figs and prunes, acid fruits and fruits juices, fresh vegetables, fats and all grain preparations. It is of the utmost importance that the bowels should move regularly once a day. There is another reason for eating food in the shape of fruits or salads, which is that the body may have a sufficient supply of mineral salts.

Nuts and fruits are a splendid combination, since the fat of the nuts and the sugar of the fruits supply the energy and heat producing substances. Fruit sugar indeed is merely a digested form of starch—the digestive process having been accomplished by the heat of the sun in the ripening of the fruit. Fruits contain no fat and practically no starch, and with the exception of the fig, the banana, and a few others, they contain so small an amount of proteid that that element may be considered practically missing. Fruits are used for the sugar, the acids, and the water they contain. Nuts and fruits may be eaten and digested raw by persons who have sound teeth, and who will thoroughly masticate these foods.

Bananas should never be eaten until they are completely ripe, this condition being shown by the appearance of black or dark brown spots on the skin. When in this condition they are usually thrown into the garbage can by the fruit dealer.

Before eating them, one should scrape off the outside fluff, which is next to the skin, as experiments have shown this to be highly indigestible. Eaten when ripe no fruit is more nutritious or delightful than the banana. The only way in which unripe bananas should be used is baked, the same as apples, when they make a succulent and nutritious dish.

Sweet apples will digest more quickly than any other raw fruit substance; but if eaten raw, apples should be thoroughly ripened, and most thoroughly masticated, else hard pieces of apple will enter the stomach and give rise to fermentation. A mealy apple is considered by physiologists as a food substance almost completely predigested, and ready for absorption. If such an apple is reduced to a smooth pulp by chewing, it will pass out of the stomach within an hour. Baked, sweet apples are digested by persons whose stomachs will not tolerate any other fruit.

The acid of sour apples is an excellent corrective for foul conditions of the stomach, such as exist in biliousness. The germs of typhoid, of cholera, and others likely to produce acute disease, are quickly killed by solutions of citric and malic acids, the acids of the lemon or the apple. The juice of a lemon added to an ounce of water will render that water sterile within half an hour, even though it may contain the germs of typhoid fever and cholera. The antiseptic properties of fruit juice render it exceedingly valuable as a means of killing the germs in the stomach and the alimentary canal; a fact which explains the benefits derived from various “fruit cures,” which have been for many years practiced in Europe, and more recently have been employed in various parts of the United States.

The indigestion which many people complain of as arising from the use of fruit comes not from fruit in itself, but from its improper use in combination with other foods with which it does not agree. It is sometimes supposed, for instance, that fruits conduce to bowel disorders; but the truth is that an exclusive diet of fruit is one of the best known remedies for chronic bowel disorders. Care should be taken, however, to avoid fruit juices which contain a large amount of cane sugar; only the juices of sweet fruits should be employed, or else a mixture of sour and sweet fruit juices without sugar. Raisins, figs, prunes, sweet apples and sweet pears may be mixed with sour fruits. Fruit that is sweetened with sugar to a large extent is indigestible, since cane sugar often proves an irritant: while the combination of cream and sugar which is so often used with many fruits is a very bad one. Fruits should be eaten with vegetables only if both are thoroughly masticated, for the reason that the cellulose in vegetables takes a long time to digest, while fruit takes a very short time, and is held in the stomach and ferments. Fruit combines well with cereal foods, breads, and the like, and with nuts.

WHAT COOKING DOES FOR GRAINS

Cooking does for grains what the sun does for fruit; it performs a preliminary digestion. In undergoing digestion the starch in food passes through five stages: first, it is converted into amylodextrin, or soluble starch; second, erythrod extrin; third, achroödextrin; fourth, maltose; and fifth, levulose, or fruit sugar. Cooking can carry the starch through the first three of these processes, rendering it ready for almost instant conversion into maltose, on coming into contact with the saliva in mouth and stomach. In the intestine maltose is converted into levulose or fruit sugar and the process of digestion is completed. Modern science has shown by experiments that the preliminary digestive work done by cooking varies greatly with the method of cooking adopted. There are practically three methods used in the cooking of cereals, kettle cooking (that is, boiling and steaming), over cooking, or roasting, and toasting, or dry cooking. Kettle cooking changes the raw starch into soluble starch; in other words, it carries the starch through the first step of the digestive process. Baking, or very prolonged kettle cooking, will convert the starch into erythrodextrin, the second stage of starch digestion. Toasting, or dry cooking, in which the starch is exposed to a temperature of about 300 Fahrenheit, advances the starch one step farther, yet.

ABOLISH THE FRYING PAN!

One important thing to remember in connection with cooking is that fried foods, the use of which is so prevalent in America is an unmitigated evil. “Of all dietic abominations for which bad cooking is responsible, fried dishes are the most pernicious,” says Dr. Kellogg. “Meat fried, fricasseed, or otherwise cooked in fat, fried bread, fried vegetables, doughnuts, griddle cakes, and all similar combinations of melted fat or other elements of food are most difficult articles of digestion. None but the most stalwart stomach can master such indigestibles. The gastric juice has little more action upon fats than water. Hence a portion of meat or other food saturated with fat is as completely protected from the action of gastric juice as is a foot within a well-oiled boot from the snow and water outside.”

This same reason explains why rich cake, shortened pie crust and pastry generally, as well as warm bread and butter disagree with sick stomachs and are the cause of many diseases. Not only does the interfering with the digestion of the food by its covering of fat set up fermentation, but the chemical changes occasioned in the fat itself develop exceedingly injurious acids which irritate the mucous membrane of the stomach, causing congestion and sometimes even inflammation. The frying-pan is an implement that should be banished from every kitchen in the land.

For many years past America has been deluged with various breakfast foods, the virtues of which have been loudly trumpeted. Yet in the ordinary process of cooking these breakfast foods, oatmeal, cracked wheat, etc., it is seldom that more than half the starch completes even the first stage of conversion. Hence it cannot be acted upon at all by the saliva, which does not begin the process of digestion with raw starch. The use of imperfectly cooked cereals is without doubt responsible for a great share of the dyspepsia prevailing among Americans. Oatmeal porridge, and similar preparations, unless most thoroughly cooked, are not wholesome foods, and when cream and sugar are added, there is a combination calculated to create a marked form of dyspepsia. Cereals must be cooked dry in order to be thoroughly cooked, and when prepared by dry cooking or toasting, they are well adapted to the human stomach, are easily digested and in combination with fruits and nuts, constitute a good dietary. Cereals must not only be cooked dry in order to be promptly digested, but they should also be eaten dry. Experiments show that an ounce of dry, well cooked cereal food when well masticated will produce two ounces of saliva; whereas mush, gruel, and other moist cereal foods cause the secretion of only a very small quantity of saliva, less than one quarter of the amount produced by the same food in a dry state.

In connection with the cooking of cereals, it is well to remember that the chief vegetable proteid, gluten, is also rendered very much more easily digested by thorough cooking. On the other hand, the digestibility of animal proteids, in the form of both meat and eggs, is greatly diminished by cooking.

The potato is another important foodstuff; when it is well cooked it is one of the most nutritious and wholesome of all foods. The starch of the potato is more easily digested than that of cereals, as has been shown by numerous experiments conducted of late in Germany and in America. A good way of preparing potatoes so as to increase their digestibility is to cut them into slices after cooking and then place in an oven until slightly browned; but the admixture of fat of any sort should be avoided.

On the other hand, cabbage is one of those vegetables which is less likely to create stomach trouble when eaten raw than if cooked. The food value of cabbage, however, is so small that it is hardly worth eating, save as a relish. The same remark may be made as to such other foods as celery, spinach, and greens of all sorts. They are only valuable for the sake of the small quantity of mineral salts they contain, and for the sake of adding another taste to the bill of fare. Onions have a higher nutritive value, but this is offset by their containing an irritating volatile oil, which when onions are used too freely may harm the mucous membrane. The onion plays its best part in cookery when used as a flavoring substance.

The mushroom is another article of food, popular among those who can afford it, which modern science shows to be practically unfit for human use. Paradoxically enough, although chemical analysis of mushrooms show them to be so rich in proteids as to earn for them the name of vegetable beefsteak, yet researches have shown that these proteids are not available by the body, and hence that mushrooms have no nutritive value whatsoever.

DAIRY PRODUCTS NEED ATTENTION

Milk is commonly considered a wholesome and easily digested food, but this is true only in a modified sense. Thousands of infants die annually because of indigestion set up by the use of cows' milk, and hundreds of adults are more or less injured by the too free use of unsterilized cows' milk, which produces biliousness, sick headache, inactive bowels and a variety of other disturbances. These are not alone due to the toughness of the curds which are formed by milk, and which set up fermentative and putrefactive processes in the stomach unless the milk is thoroughly cooked beforehand.

Federal departments at Washington were, not long ago, almost crippled by the prevalence of typhoid fever among the employees; and the public health service under Surgeon-General Walter Wyman traced more than ten per cent. of the cases to the milk supply. Professor Lafayette B. Mendel of the Sheffield Scientific School of Yale University, told one of the writers of this book that he went to a certain city that had suffered an epidemic of typhoid, and made a map showing each house that had contained a case of typhoid fever. He made a similar map showing the houses where certain milkmen stopped—and the two maps were almost completely identical. It has also been established beyond a doubt that tuberculosis is communicated from the cow to the human being, and in certain sections of the world it is believed that milk from tubercular cows is the chief channel of infection. It has been shown that even if the udder of a cow be healthy, a tubercular cow may give infected milk, and that the presence of a single

tubercular cow in a herd may be responsible for the infection of the milk of healthy animals. Several international medical congresses have lately declared that all milk should be boiled in order to kill the germs.

[Illustration: PROF. LAFAYETTE B. MENDEL, PH.D., YALE UNIVERSITY, Who has carried on researches in conjunction with Prof. Chittenden.]

The United States Department of Agriculture issued in Circular No. 111 of the Bureau of Animal Industry, and in Circular No. 114, the recommendations made by a conference of some twenty of the foremost scientists of the United States, and few more important documents concerning the public health have ever been issued by a government. In brief, these recommendations may be thus stated: Raw milk is highly dangerous. Boiling or pasteurizing kills the disease germs and makes the milk safe without seriously impairing the taste or digestibility. Milk produced under the most ideal conditions, such as “certified” milk, is only relatively safe. Pasteurization, when properly done, makes the milk absolutely safe.

Butter, of course, is subject to all the arguments that can be advanced against milk, with the additional one that it is even more subject to infection with germs than milk itself, since the time that elapses between its manufacture and its consumption is usually far longer than the time that elapses between the drawing of milk from the cow and its use. Only butter that is made from sterilized cream should be used.

Cheese, of course, is open to all the objections urged against unsterilized milk and butter, and in addition has a disagreeable quality all its own. The cheese eater may at any time swallow a serious or even a fatal dose of “cheese poisons,” which are substances produced in cheese by the action of germs. These are not ordinarily present in sufficient quantity to render their presence apparent; nevertheless, a great number of cases of cheese poisoning are annually reported by various boards of health all over the country. Cheese made from sterilized milk is less open to these objections. A delicious cottage cheese may be made from Yogurt milk.

The too free use of sugar at the table and in cooking, not only in its pure form, but in the shape of preserves, syrups and sweet beverages, has been shown to be a most prolific source of injury to the stomach. Sorghum, maple sugar, and maple syrup are essentially the same as cane sugar and molasses. It has been shown that if we eat freely of fruits we will obtain all the sugar our system requires in a form that is easily digestible.

The constitution needs quite a good deal of fat; wholesome fats are contained in nuts, and in cereals, and are also provided liberally by ripe olives and olive oil. Emulsified fats are those in which the minute particles are broken up; and these are far more readily absorbed by the tissues of the body. The fat in ripe olives is emulsified fat—as likewise is olive oil when used in mayonnaise dressing. It should not be mixed with vinegar, however, as vinegar is an irritating substance that works harm, when used freely, to the mucous membrane of the stomach. Lemon juice is not only much safer, but makes a much more delicious dressing.

The objection which applies to vinegar, applies also to pepper, mustard, and other condiments and spices.

The too free use of salt, of which nearly everyone is guilty, is another habit upon which modern physiologists frown. While salt is essential, it is contained as an element in many foods, and there is no more reason why it should be sprinkled upon each and every article of food that is taken than we should have castors containing all the other kinds of inorganic salts, that the system needs, and which are supplied to it in fresh foods. Salt using is merely a habit, and a disastrous one, since it has been shown to be one of the factors in the causation of kidney troubles, such as Bright’s disease.

The large use of glucose in the form of candy, syrups, adulterated honey, and various sweets which are in common use, is said by physiologists to be responsible for a large number of cases of diabetes, a disease which is rapidly increasing in America. There is now produced a malt sugar, called malt honey or “meltose,” which can be used freely for all the purposes that cane sugar is used.

The case of food reform against fish would merely lead to the relating of the arguments against meat. Fish contains nearly seven per cent. of uric acid. It is exposed like meat to the presence of tape worms and other parasites. Even when fresh out of the water its flesh is filled with fatigue poisons, the result of its struggles to escape from the net or the hook; and Mosso of Turin and other authorities have shown that these fatigue toxins have a bad effect upon the body. No food will so quickly decompose and putrefy as fish, and unless perfectly fresh it will always be found full of the putrefactive bacteria which are the active agents in causing autointoxication.

It may be stated, however, that the person who follows that careful and helpful mode of eating recommended and practiced with such marked benefits by Horace Fletcher and his converts, will assuredly minimize the dangers that lurk unsuspected by the uninformed in many of our commonly used foods, and will derive a greater benefit from all food than it is possible for those to gain who eat in the hasty and careless fashion characteristic of most Americans.

VII

HOW OFTEN SHOULD WE EAT?

WE have discussed the question how to eat and what to eat; there remains the question of when to eat. English people, as a rule, eat four meals a day. The French are practically a two meal a day nation, eating a very light breakfast.

Of late years there has been a strong tendency on the part of American dieticians to advocate a reduction in the number of daily meals, the ideal aimed at being the establishing of the custom of two meals a day, with at least six hours intervening between them.

It may be asked whether appetite is not a safe guide to follow, and whether it is not the part of wisdom to follow personal inclination in the choice and quantity and number of meals. Does not a study of dietetic customs and habits definitely decide the essential rules of dietetics? While it is true that habits and customs are very strong factors in everybody's life, yet it is also true that they are very unreliable guides. We are constantly acquiring new habits, and sloughing off old ones; and even the most deeply impressed of habits may be changed for others. And while the common customs of mankind would seem to indicate that three or four meals a day is the rule, at least among civilized nations, yet the facts are that the most primitive people take one meal a day, and the great majority of people in the world, as a rule, eat certainly less than three.

TWO MEALS A DAY THE BEST

Physiological facts argue for the two meal plan, or else for very light and easily digested food, if an extra meal be taken.

Healthy digestion requires at least five hours for its completion, and one hour for rest before another meal is taken. This makes six hours necessary for the disposal of each meal. If food is taken at shorter intervals than this, when ordinary food is eaten, the stomach will be allowed no time for rest. Again, if a meal is taken before the preceding meal has been digested and has left the stomach, a portion remaining, one is likely to undergo fermentation, in spite of the preserving influence of the gastric juice; thus the whole mass of food will be rendered less fit for the nutrition of the body, and the stomach itself will be likely to suffer injury from the acids developed.

[Illustration: MR. UPTON SINCLAIR'S CHILDREN, Well nourished on two meals a day.]

These facts make it plain why eating between meals is a gross breach of the requirements of good digestion. The habit of nibbling at confectionery, fruit, nuts, and other things between meals, is a positive cause of dyspepsia. No stomach can long endure such usage. There is a continual irritation of the mucous membrane of the stomach, and a continual excitation of the glands, which, in the long run, work great harm.

The same reasons which are advanced against the habit of eating between meals fit the case of irregularity of meals. Those who have regular duties, regular hours of work, should have regular meal hours. The human system is continually forming habits, and seems in a great degree dependent upon the performance of its functions in accordance with the habits that are formed. This fact is especially observed in respect to digestion. When meals are taken at regular times the stomach becomes accustomed to receiving food at those times, and is prepared for it. If meals are taken irregularly, the stomach is taken by surprise, so to speak, and is never in that state of rest in which it should be for the prompt and perfect performance of its functions. The habit which many business and professional men form, in the stress of their occupations, of allowing their meal hours to be intruded upon, at times depriving themselves of a meal, will undermine the best digestion in the long run. There is no physiologist who would not endorse the following words of Kellogg: "Every individual ought to consider the hour for meals a sacred one, not to be intruded upon under any ordinary circumstances. Eating is a matter of too momentous importance to be interrupted or delayed by ordinary matters of business or convenience. The habit of regularity in eating should be cultivated."

DON'T EAT BEFORE SLEEPING

The meal which most people would find it advantageous either to drop altogether, or to reduce in quantity, is supper. The physiological law which is now come to be recognized is, that the brain must be active to insure good digestion; and that the stomach must be empty to insure good sleep. That sense of drowsiness which so often follows a hearty meal is not a physiological condition; it is not evidence of a naturally sedative effect in eating; but is really an evidence of indigestion. Those who practice eating before retiring often sleep soundly until an hour or two after midnight, then awake, and find difficulty in getting to sleep again. This is due to irritation of the solar plexus set up by the labor of digesting under unfavorable conditions. The lack of appetite for breakfast after a late supper is evidence of the exhausted state of the stomach. Fruits and cereals are the ideal supper rather than the ideal breakfast—though good at any time!

DRINKING AT MEALS

It is nearly always the case that a hasty or over-hearty eater is also in the habit of drinking copiously of water or other fluids at his meals. He “washes his food down” instead of legitimately drinking. The body, of course, needs liquid, but, as a rule, meal times are not the times for the taking of this liquid supply; except for what is contained in the food itself. The hasty eater thus associates two great evils.

Liquid of any kind in large quantity is inimical to digestion, because it delays the action of the gastric juice, and weakens its digestive qualities, and also checks the secretion of saliva. In case the fluid taken is very hot, as tea, coffee, cocoa, or a considerable quantity of soup—it relaxes and weakens the stomach. On the other hand if it is very cold, it checks digestion by cooling the contents of the stomach, and reducing its temperature to a degree at which digestion cannot proceed. Even a small quantity of cold water, ice cream, or other very cold substance will create a serious disturbance if taken into a stomach where food is undergoing digestion. The process of digestion cannot be carried on at a temperature that is less than the body, which is about one hundred.

The old notions about the processes of digestion were chiefly drawn from the experiments of Dr. Beaumont made nearly a hundred years ago up in Northern Michigan, around Mackinac; with a Canadian hunter, Alexis St. Martin, as the subject. Most people have probably read of St. Martin and Beaumont in the physiologies they studied in their school days. Beaumont was a very capable physician, and a man of the truest scientific spirit. It happened that through an accident he was given an opportunity to make the most valuable contribution to the study of the stomach of man that so far had been furnished by any investigator. The hunter, St. Martin, had suffered a gunshot wound in his stomach, and Beaumont kept him alive for years with the wound open so that he might study the movements of the man’s interior organs. For the first time, here was a human body with a window in it, so to speak, and through this window the scientist patiently watched and studied for years. Of course, however, the window gave only a limited view of what was going on inside this particular house of life, and a great number of Beaumont’s ideas and theories have been proven erroneous; nevertheless, he obtained much important knowledge. When Dr. Beaumont peered through that curious window which he made in the stomach of Alexis St. Martin, he noticed that when the latter drank a glassful of water at the usual temperature of freshly drawn well water, the temperature of the food undergoing digestion fell immediately to 70. The process of digestion was checked absolutely and did not resume until the body had regained its proper temperature, which it did not do for more than half an hour.

Another way in which drinking at meals proves harmful is because of the fact that particles of food not thoroughly masticated are washed from the mouth into the stomach. If any drink at meals is taken at all, it should be a few minutes before eating. Of course, sipping of a little water will not be harmful, if care is taken not to sip at the time when food is in the mouth. It will be found, however, that unless the meal is composed of very dry foods, there will be little inclination to drink at meals. When, however, the food is rendered either fiery or irritating with spices, and other stimulating condiments, it is small wonder that there is an imperious demand for water or liquid of any kind to allay the irritation.

HOW THE BODY PRODUCES “APPETITE JUICE”

He who is really hungry, however, has no need of condiments, and usually small relish for them.

The old saying that hunger is the best sauce is one of those proverbs of the people which modern science is proving to be firmly established on truth. No sauce can equal appetite. Experiments by Professor Pawlow of St. Petersburg, Director of Department of Experimental Physiology in the Imperial Literary School of Medicine, have shown that there is a real “appetite juice” formed by the body when it is hungry.

Appetite, and hunger, are not synonymous terms with the mere habit-craving for food which most people consider to be either appetite or hunger. Real hunger, or appetite, only comes to the body when the body has earned it. There must be an expenditure of tissue, which the body requires to be repaired; or there must be a real need for energy to carry on work before the body will manifest its need for energy-supplying material. In other words, the body cares nothing about our likes or dislikes, our whims or our fancies, in the nature of food, save when it has a real need for food. Professor Chittenden demonstrated that most people simply eat the entire round of meals from mere habit. The disturbance when for any reason they miss one or two meals from the accustomed routine is simply the outcry of a habit and not the outcry of a real need. While Dr. Kellogg advises that no meal be missed, yet he also strongly advises us not to eat unless really hungry, merely drinking a little fruit juice or something of the kind at the meal hour in order to keep up the normal action of the digestive organs.

The digestive juice which is manufactured by the body when it is really hungry and food has been given to it has been shown by Pawlow and Hanecke to be the most important element in digestion. The chemical juices produced in the stomach and intestines while food is in them is of small importance and value compared with the juices that are formed while food is being chewed when the body has a good appetite or is really hungry.

This juice begins to flow at the very sight of food, and continues to from three to five minutes after beginning mastication. The production of juice in the stomach is stimulated by the contact of food with the mouth, and only during that contact; so it is obvious that the longer the food is held in the mouth, if it is held there in enjoyment, and the more completely it is chewed, so long as chewing is accompanied by taste, the more thoroughly are the flavors set free by the act of chewing, and the higher becomes the stimulating effect of these flavors upon the psychic centers which cause the appetite juice to flow into the stomach.

These facts prove the dependence of gastric digestion, or stomach digestion, upon mastication. Pawlow was experimenting with gastric juice when he hit upon this demonstration; and he has concluded that we cannot have gastric digestion at all well without thorough mouth digestion; that the complete mastication of food, in other words, is the thing necessary to prepare the stomach to receive the food. Thus, if you chew your food well, the food will be predigested in the mouth, and when it enters the stomach it will find already there waiting for it not only enough gastric juice to digest it, but just the particular kind of gastric juice that is needed.

Pawlow turned this discovery of his to a very practical use. He has a dozen or more healthy dogs which he calls his Dog Dairy. From these dogs he collects daily a quart or more of gastric juice, or appetite juice; and the dogs produce this large quantity without taking a particle of food into their stomachs. The juice is carefully filtered, and bottled and shipped all over the world to those physicians who are in touch with Pawlow and his work, and by them are administered to human patients. It is given to those patients who are deficient in gastric juice, and is used in very obstinate cases of indigestion.

Pawlow collects his juice by having openings made in the throat and in the stomachs of the dogs. When the dogs are hungry they are given food of kinds which they particularly like, and they are allowed to smell the odor and to become excited over the prospect of eating it before they are actually allowed to have it. With the first sight and odor of this food, the dogs begin to secrete the appetite juice, which flows from the opening made in their stomachs through tubes into receptacles. Then when they begin to eat their food, the food does not reach the stomach at all, but simply passes through the openings in the throat into a receptacle before the dog, and the dog can go on eating the same meal over and over again. They thus enjoy themselves thoroughly for a long time. When the appetite juice ceases to flow, the process of feeding them in this manner stops, and they are given a real meal.

VIII

HEALTH AND THE MIND

This account of Professor Pawlow's experiment leads directly to the all important subject of the influence of mental states upon digestion and assimilation. Dr. Saleeby has published a book called "Worry, the Disease of the Age"—the very title of which shows the attitude of physicians upon this question; and the bad opinion which mankind has always entertained of such states of mind as "the blues" has now been scientifically justified. The effects of pain and pleasure upon digestion have been demonstrated by actual experiments in the laboratory of the St. Petersburg professor.

A vivid account of these experiments has been given to the writers by Dr. J. H. Kellogg, who witnessed them about a year ago. Dr. Kellogg writes:

“Professor Pawlow took Professor Benedict and myself into a quiet corner of his laboratory, and there we found a dog that had his salivary glands or ducts arranged so that by means of little tubes passing through the skin all the saliva, instead of passing down his throat, passed out through the tubes and could be collected in small glass bottles suspended beside his neck.

“The dog had been prepared beforehand by the attendant. Little empty bottles were attached to the collecting tubes, and as soon as the dog saw Pawlow, he seemed to be very happy, and wagged his tail, and his eyes gave evidence of satisfaction; but there was no flow of saliva until Professor Pawlow brought near to his nose a bottle containing some powdered meat. He took out the cork in the presence of the dog, turned out a little of it in his hand, shook it in the bottle and brought it near to the dog’s nose. The dog began to sniff it, licked his chops, snapped his jaws, reached out after it, and in less than two minutes the saliva began to flow very profusely, and it was not more than fifteen or twenty seconds before the saliva was pouring down into the bottles.

“Professor Pawlow, then, after holding the bottle out before the dog for about thirty seconds, put the stopper into it, and put it behind him out of sight, and in a very few seconds the saliva ceased to flow. Then he brought it back again, showed it to the dog, brought it near his nose, allowed him to smell it but kept it just out of his reach all the time, and the saliva poured out again freely. He continued this until the dog finally made up his mind he was not going to get any meat, and when the powder was brought near to him he paid no attention to it, but turned his head around and looked very disappointed and very ugly, and at that point, the saliva ceased to flow.

“That was a very remarkable thing to me. The meat was right there, he could smell it, but he knew he was not going to get it, so he was angry, and as his state of mind changed, the secretion of saliva was wholly arrested. I was very much surprised. Of course, I believe thoroughly in the importance of being in a happy state of mind when eating, but I really did not appreciate thoroughly the importance of those things; I did not fully appreciate how positive an inhibitor of the activity of the salivary glands an unhappy state might be.

“But a common experiment made in India shows the same idea. When an Anglo-Indian has lost anything of value, he has his whole family of servants brought to him to find out which one has stolen it. A common test is to stand them all up in a row, and then to give each one a morsel of dry rice to chew. They must chew this rice for five minutes, and then the master goes around and examines each man’s mouth. The mouth which is dry is the mouth of the culprit, and the state of that man’s mind has the effect of arresting the flow of saliva. Pawlow has shown that this is a positive physiologic law and operates upon the dogs as well as upon human beings.

“Another experiment astonished me even more than this. We followed Pawlow down through a long narrow hall and upstairs into a room which was small and secluded, in a very quiet part of the laboratory, remote from any noisy occupation, and there we found a brown dog standing on a high table. It was a delicate and very intelligent looking animal. The attendant sat near by, and the dog was prepared as the other had been. As we came in, the Professor beckoned to us to sit down on a little bench beside the wall and indicated that we should be quiet. He stepped up to the dog, looked at him, and the dog recognized him with a smile in the dog’s way of smiling!—and presently the saliva began to flow.

“Professor Pawlow was very much surprised. We had come into the room and he had offered the dog nothing, but the saliva was flowing. That was contrary to his expectation. He looked with considerable astonishment at the attendant. The attendant quietly said, ‘You have been feeding meat to the other dog, and he smells the meat on your hands.’

“The dog had such a keen sense of smell that the odor of meat on Pawlow’s hands even at a distance of several feet was sufficient to cause the saliva to flow. So he went out, washed his hands and came back. At this time, not a drop of saliva was flowing. The arrangement was such that every particle secreted must come outside of the mouth into these bottles. While we were waiting in silence, watching the dog quietly, suddenly the attendant pressed his foot without making any motion of the body at all, upon a little lever beneath his toe and the result was the causing of a high musical note to be sounded, a very high pitched tone.

“Instantly, in less than three seconds, the saliva was flowing into the tube. We waited a little while until the saliva ceased to flow, then the note was sounded again. Instantly the saliva began to flow.

“Professor Pawlow has been experimenting upon this line for a long time. Other experiments were made. One interesting experiment was with a large number of dogs. He had upon one counter a long row of dogs, about a dozen, which had their stomachs fixed in such a way, and their throats fixed also in such a way, that upon the secretion of the gastric juice in the stomach the juice would flow out into a flask.

“The dogs were suspended in a sort of harness. They had had their throats fixed so that food instead of going into the stomach came out at the throat. So as the dog ate the food, the food fell back into the plate and the dog continued eating the same breakfast over and over. These dogs had been eating the same breakfast for four hours, from six to ten o’clock in the morning, and they were still eating, and just as hungry as ever because there was no food entering their stomachs at all and their appetites were growing keener every moment, and they were having a wonderfully good time. I thought that some people I have met might enjoy such an arrangement. This really has the same effect without having your throat cut.

“I noticed that if these dogs got disgruntled, or tired, or dissatisfied, then the gastric juice would cease to flow. Sometimes the food, having been chewed a very long time, lost its flavor, and the dogs secreted no more juice; then the attendant would come along and put a little fresh food into the plate and the dogs would seize this with great avidity, and the gastric juice would begin to flow again in a perfect stream.

“These experiments have demonstrated in the most positive manner the definite connection there is between psychic conditions and the process of digestion, and have shown us that the food must be palatable, that it must address the olfactory sense agreeably, and that the mind must be in a happy state in order that the digestive process may proceed.”

And then Dr. Kellogg goes on to tell of the work of Professor Cannon, of Harvard University, who actually has made visible the digestive processes in the stomach by means of the X-ray. By feeding cats food colored with certain substances which are impervious to the X-rays, he was enabled to photograph all the actual movements of the organs concerned in the acts of digestion. It was demonstrated that certain emotions, such as anger and fear, positively stopped the whole process of digestion.

Depressing thought will affect injuriously the circulation of the blood; it will also affect the breathing. The mere attitude of the body assumed by the despondent person has its bad influence. The head droops in a melancholy fashion—and this very attitude prevents normal action of the lungs and the blood veins. Depressing thoughts destroy the appetite; and when the body does not receive its proper nourishment, the blood becomes impoverished.

“Any severe anger or grief is almost certain to be succeeded by fever in certain parts of Africa,” says Sir Samuel Baker, in the British and Foreign Medico Chirurgical Review. “In many cases, I have seen reasons for believing that cancer had its origin in prolonged anxiety,” says Sir George Paget, in his “Lectures.” “The vast majority of the cases of cancer, especially of breast or uterine cancer, are probably due to mental anxiety,” says Dr. Snow, in the London _Lancet_. “Diabetes from a sudden mental shock is a true, pure type of physical malady of mental origin,” says Sir B. W. Richardson in “Discourses.” “I have been surprised how often patients with primary cancer of the liver lay the cause of this ill health to protracted grief or anxiety. The cases have been far too numerous to be accounted for as mere coincidences,” says Murchison.

“Eruptions on the skin will follow excessive mental strain. In all these and in cancer, epilepsy and mania from mental causes there is a predisposition. It is remarkable how little the question of physical disease from mental influence has been studied,” says Sir B. W. Richardson.

“My experiments show that irascible, malevolent and depressing emotions generate in the system injurious compounds, some of which are extremely poisonous; also that agreeable, happy emotions generate chemical compounds of nutritious value, which stimulate the cells to manufacture energy,” says Elmer Gates, the celebrated American scientist. Gates’ experiments show with minute exactitude just how it is that one’s impalpable thoughts and emotions affect the battle of the blood, and his work makes it easier for one to understand and appreciate the portion of truth underlying such manifestations as the New Thought and Christian Science movement. There can be no doubt that men and women have practically remolded their bodies and changed the whole course of their lives by using the impalpable yet potent force of their wills. Sometimes these have been men and women seemingly without a vestige of will; and yet, by comprehending the necessity for will, they took the first steps towards attaining possession of it. Many very remarkable stories could be told illustrating this point. Professor William James, of Harvard, introduced one of the writers to a man who had been afflicted with what had seemed a helpless case of mental trouble, accompanied by physical ailments which were rapidly breaking him down; and this man had affected a complete cure through his own unaided efforts. He resolved that he could be cured, and cured he was.

We remember another instance; this time of a consumptive; a man who was so far gone that all the physicians gave up his case as hopeless. To all intents and purposes he was already a dead man, when there came to him the light of a new hope. He had spent a great deal of money in taking various “treatments” for tuberculosis, without deriving permanent benefit, and then had come to believe utterly that in only one way was there hope for the consumptive, namely, by living entirely in the open air. When seemingly

at his last gasp he arrived at a branch of the Battle Creek Sanitarium at Boulder Creek, Colorado. In certain photographs of this establishment you may see on a bare hillside that stands back of the building, a narrow foot-path. This path has many turnings and windings in its lower course, but towards the top of the hill it aspires upward in a straight line. That trail was made by the consumptive who had determined that he would live, crawling on his hands and knees up the side of the hill. He positively refused to go under a roof for any consideration whatsoever. His meals were brought to him where he lay on the road side. At first he was so weak that he could only go a few feet in the course of a day, and had to drag himself along in a wavering line. But he began to improve—he went on improving—until, finally, along the track on which he had crawled he was running at top speed.

And a little while ago this man was one of the athletes who took part in Professor Irving Fisher's endurance competition between flesh-eating athletes and vegetarians; and he proved to be best of them all! He doubled the best record made by any Yale man in the deep-knee bending contest. The most enduring Yale man was able to make the deep-knee bend—which is a very severe test of physical endurance—twelve hundred times. The consumptive who had cured himself went twenty-four hundred times. He thinks nothing of a ten or fifteen mile ran before breakfast in the morning.

It is important to apply these truths to the question of nutrition. It is positively harmful to eat food when one is gloomy or low spirited or worried or angry.

You may object to this that you cannot at will make an optimist of yourself at meal times, and turn on a flow of good humor as you draw water from a tap. But you can at least refrain from eating, and if you do you will discover that the real hunger which is bound to develop is a very strong emotion. It will drive away any ordinary attack of the blues very quickly; and will call up pleasant anticipations of the joy of food to assist the digestive processes.

IX

THE CASE AS TO MEAT

"I wish there was a science of nutrition worthy of the name," writes Bernard Shaw in a private letter. "The mass of special pleading on behalf of meat eating on the one side and vegetarianism on the other, which calls itself the science of metabolism to-day, seems to me to be so corrupt as to be worthless." The fact that Shaw himself is a perfervid vegetarian lends additional significance to this statement. Until quite recently the advocacy of either dietary has been based upon considerations the opposite of physiologic. It has been the sentimental aspects of the controversy—vegetable versus animal foods—which have received most emphasis. The vegetarian supported his position on the ethical ground that the eating of animal food, involving as it does the taking of life, is wrong. On the other hand, the advocate of meat eating based his arguments on the support given to it by common custom, and a belief that a meat diet is that which supplies vigor and manly force. As Dr. Woods Hutchinson, the most prominent of the champions of meat eating, puts the case: "Vegetarianism is the diet of the enslaved, stagnant, and conquered races, and a diet rich in meat is that of the progressing, the dominant and the conquering strains. The rise of any nation in civilization is invariably accompanied by an increasing abundance in food supplies from all possible sources, both vegetable and animal."

At the same time, even Dr. Hutchinson admits that human life can be maintained upon a vegetarian diet. "Nearly one-half of the human race," he writes, "has been compelled from sheer necessity to prove that thesis in its actual experience; but we find absolutely no jot of evidence in support of the contention that there is any advantage or superiority in the vegetable diet as such—no more than that there is any inherent superiority in a pure animal diet as such.... There is no valid or necessary ground, so far as we have been able to discover, for the exclusion of any known article of food, whether vegetable or animal, from our diet list in health."

Dr. Hutchinson's views were printed in a popular magazine, and have been very widely quoted, but he seems to have written without paying attention to a number of scientific investigations which suggest ample grounds for the radical reduction of the meat portion of the ordinary diet. Among these are the experiments of Dr. Horter of New York, Professors Mendel, Chittenden and Fisher of Yale, Dr. Fenton B. Turck, and such world-known physiologists as Combe of Lausanne, and Metchnikoff, Gautier, and Tissier of Paris. The elaborate researches of Dr. Kellogg of Battle Creek are dismissed by Woods Hutchinson, because of the fact that Dr. Kellogg not only upholds the exclusion of meat from the diet for purely scientific reasons, but also on ethical grounds. The writers of this book, however, have discarded meat from their dietary for scientific reasons, paying as little attention to the ethical side of the question as Dr. Hutchinson could desire. They will give in this place a brief summary of these scientific reasons.

THE BELGIAN EXPERIMENTS

We have already told of the experiments whereby Professor Fisher of Yale proved the superior endurance of vegetarians over meat-eaters. It happens that experiments of the same nature were carried on at about the same time by two women scientists in Belgium, Dr. J. Ioteyko, head of the laboratory at the University of Brussels, and Mlle. Varia Kipiani. They studied the question of vegetarianism by several methods, and became convinced that the vegetarian régime is a more rational one.

Their experiments were for the most part comparisons of strength and endurance between men and women subsisting on the usual high proteid, or flesh diet, and men and women who for longer or shorter periods had abstained entirely from meat. The results tally remarkably with those obtained by Professor Fisher. So far as strength was concerned, very little difference was discovered between vegetarians and "carnivores." In endurance, on the other hand (and it is endurance that most people need) a very remarkable difference was found, the vegetarians surpassing the carnivores from 50 to 200%. The Brussels investigators found also that the vegetarians recuperated from fatigue far more quickly than the meat eaters, a discovery which was one of the most remarkable features of the Yale experiments.

[Illustration: MR. SINCLAIR'S CHILDREN, Brought up according to good health principles.]

In commenting upon the Belgian experiments, Professor Fisher writes:

DR. TURCK'S INVESTIGATIONS

It is possible that flesh-eating, as ordinarily practiced, is injurious both because of excessive proteid and because meat, as such, contains poisonous elements. It is well known that Liebig came to repudiate the idea that the extractives of meat were nutritious, and that investigation has shown them to be poisonous. Professor Fisher also points out that Dr. F. B. Turck has found that dogs, mice, and rats fed on meat extractives exhibit symptoms of poisoning and often die. The poisonous effect is aggravated by intestinal bacteria, which find in these extractives an excellent culture medium. Dr. Turck concludes:

"(1) It is clearly evident from these experiments, which correspond to the investigations of others, that the injurious effects of meat are due not so much to the muscle proteid, myosin, as to the extractives.

"(2) That the injurious effects of the extractives are increased through the action of intestinal bacteria."

Dr. Turck does not find any evidence that the extractives in small quantities are injurious.

Dr. Turck therefore concludes that the "high liver" who uses much flesh and also an excess of starch and sugar is a "bad risk" for life insurance companies. He recommends, if meat is to be used, that the extractives first be removed by special processes, which he explains.

These investigations, with those of Combe of Lausanne, Metchnikoff and Tissier, of Paris, as well as Herter and others in the United States, seem gradually to be demonstrating that the fancied strength from meat is, like the fancied strength from alcohol, an illusion. The "beef and ale of England" are largely sources of weakness, not strength.

THE DANGER OF INFECTION FROM MEAT

It has always been conceded that by eating raw or underdone beef or pork one may acquire tape worms; and that in eating raw or underdone pork one runs the same risk of contracting that uncurable malady, trichinosis. The danger from these sources, however, is comparatively slight, since most people eat their meat well cooked; but in the view of many modern scientists all meat eaters are open to a particular form of germ infection which involves all kinds of meat, fish, flesh and fowl, cooked as well as uncooked.

Everybody knows how readily meats of all kinds, and particularly seafood, such as fish, oysters and clams, undergo putrefaction. The processes of decay in fish and animals begin within an hour or two after death, under the influence of putrefactive bacteria, which are always present in the colon, or large intestine of animals, upon the skin and in the atmosphere about them. Ordinary cooking does not destroy them, for they are able to stand the ordinary cooking temperature. Salt and smoked fish, and other meats have these germs present in vast multitudes; and beef and game that is "hung" for a long time in order to become "tender," are so far advanced in decay before they are brought to the table that every minute particle of them is alive with these germs.

These facts are granted by all; but the physiologist who favors the use of meat, says that unless excessive quantities are consumed, the healthy person undergoes little risk. The argument is, that when the germs are swallowed into the stomach they are

there destroyed by the action of the gastric juice, which is germicidal; but experiments have lately proved that some of these germs escape destruction by the gastric juice, and find their way to the colon, where they continue to multiply in the mucous which covers the intestinal wall, and thus maintain constant and active putrefactive processes in that part of the body.

THE NUMBER OF GERMS WE EAT

Dr. Kellogg of Battle Creek has lately made public the results of a carefully conducted series of observations made by Dr. A. W. Nelson, bacteriologist of the clinical laboratory of the Battle Creek Sanitarium. Various specimens of meat were purchased in the ordinary way in the market, wrapped in clean paper, and immediately taken to the laboratory, where samples were removed for observation under the microscope. The meat was then taken to the diet kitchen and well cooked, after which cultures were again made.

The germs found in meat are classed as aerobes and anaerobes. The aerobes are for the most part acid-forming germs, and comparatively harmless. But the anaerobes are poison-forming germs, and are the agents of putrefaction and of various diseases. They are to-day considered as the most potent causes of many chronic maladies, and especially of that most common of diseases, intestinal autointoxication.

Dr. Nelson found that in one specimen of raw beef, there were present per moist gram of material 105,000 aerobes and 90,000 anaerobes. On the outside of the beef after it had been fried, there were no germs present, but on the inside of the fried beef, he found 3000 aerobes and 2000 anaerobes per gram. With three other specimens of beef, that were broiled, and boiled, and roasted, respectively, the results were generally similar. Of all modes of cooking, roasting seems to have least effect upon the bacteria, for in specimen No. 3, while there were fewer bacteria than in specimen No. 1 before cooking, there were found after it had been well roasted 150,000 aerobes and 160,000 anaerobes.

In fresh fish raw there were found 870,000 anaerobes per gram; in sardines in oil, 14,000,000; while in codfish that had been soaked to remove the salt, there were found 47,600,000. In another experiment specimens of meat were secured such as were served on the dining tables of one of the prominent city hotels, and taken at once to the laboratory, where without delay bacterial cultures were made. A specimen of sirloin steak was found to contain 378,000,000 anaerobes per gram of moist material.

An interesting experiment which showed the increase of anaerobes or poison-forming germs in dead flesh, was that made with two chickens of equal size, one of which was drawn, and the other undrawn. Both were placed under the same conditions in a room the temperature of which was maintained at 70° Fahrenheit. Bacterial cultures were made at frequent intervals, with results as given in the following table, the figures showing the number of bacteria per gram of moist material.

No. 11 Drawn No. 12 Not Drawn Aerobes Anaerobes Aerobes Anaerobes

3 hrs after death 4,500 5,650 5,000 6,500 2d day 8,500 9,000 10,000 12,000 3d day 17,000 16,000 60,000 20,000

It must be remembered that these chickens were freshly killed, and that the anaerobes had no such opportunity to increase as in ordinary market beefs.

Specimens of several other kinds of meat were purchased in the market, and at once taken to the laboratory for study. Cultures were made immediately on reaching the laboratory, and again after the meat had been allowed to stand (covered) at room temperature for twenty hours. The following table shows the results of the bacterial counts:

BACTERIA PER GRAM (MOIST)

Immediately after purchase

Specimen Aerobes Anaerobes No. 13 Large sausage 560,000,000 420,000,000 No. 14 Small sausage 834,400,000 663,000,000 No. 15 Round steak 420,000,000 560,000,000 No. 16 Roast beef 252,000,000 560,000,000 No. 17 Smoked ham 47,320,000 43,120,000 No. 18 Hamburger steak 138,000,000 129,000,000 No. 19 Pork 635,600,000 126,040,000 No. 20 Porterhouse steak 31,920,000 30,800,000

After being kept at room temperature for twenty hours.

Specimen Aerobes Anaerobes

No. 13 Large sausage 770,000,000 490,000,000 No. 14 Small sausage 770,000,000 640,400,000 No. 15 Round steak 750,000,000 840,000,000 No. 16 Roast beef 728,000,000 750,000,000 No. 17 Smoked ham 616,000,000 750,000,000 No. 18 Hamburger steak 784,000,000 700,000,000 No. 19 Pork 952,000,000 1,036,000,000 No. 20 Porterhouse steak 336,000,000 700,000,000

These experiments were made in the winter time, when, because of the diminished amount of dust in the air, germs are less abundant. Even in the winter time, however, certain meat products simply swarm with germs. A specimen of raw liver examined in January was found to contain 269,800,000 bacteria per ounce or gram. Raw sausage contained 48,280,000 bacteria per ounce or gram.

“A food which introduces these deadly organisms, the anaerobes, at the rate of ten to twenty-five billions to the ounce, as do pork, beef and sausage, must certainly be classed as unclean,” said Dr. Kellogg, in summing up the report on his experiments. “When thousands are daily indulging themselves in this dietary, what wonder that Bright’s disease, enteritis, and other maladies due to germs and germ poisons are so rife and so rapidly increasing? It is quite as important to keep the inside of the body in a sweet, clean and wholesome condition as to maintain a wholesome state of the external portion of the body.”

CANCER AND MEAT EATING

That nothing could seem more definite than the connection between cancer and the practice of eating inferior meat, is the conclusion reached by Dr. G. Cook Adams, who made a series of statistical studies under the direction of the Chicago Board of Health. “There cannot be the slightest doubt,” says this expert, “that the great increase in cancer among the foreign born of Chicago over the prevalence of that disease in their native countries, is due to the increased consumption of animal foods, particularly those derived from diseased animals.” This conclusion substantiates the original deductions made by Dr. Adams from investigations carried on over a number of years in Australia and London.

Dr. Woods Hutchinson stated that the rise of any nation in civilization is invariably accompanied by an increased abundance in food supply; and the rise of these foreign born in Chicago in civilization substantiates Dr. Woods Hutchinson’s views. Receiving more wages than in their native homes, where their diet was simple, they are enabled to indulge in a meat diet denied them in Europe. The result is an increase in the death rate from cancer between the years 1856 and 1866 of 680%, while from 1866 to 1905 the increase was 232%.

In 1905 cancer was responsible for one in every twenty-three deaths, while in 1906 one death in every 21.8 was due to this horrible disease. The Italians and the Chinese were the only two of all the races represented in Chicago that do not show a far greater death rate from cancer than in their own homes. The Italians keep up the use of macaroni and spaghetti, while the Chinese adhere to their native diet of rice. The nations showing the higher mortality consume large quantities of canned, preserved, dried and pickled meats, sausages, etc. It was also shown that the bulk of the fresh meat prepared at the plant of a slaughtering company was stock condemned by official inspectors, and this was the meat eaten by the poor.

INVESTIGATIONS IN NEW YORK

Dr. W. H. Guilfoy, of the New York Health Department, recently published the results of investigations of the death rate among foreigners in New York, and showed that cancer, heart disease and chronic Bright’s disease have increased alarmingly in recent years, and his statistics show that foreigners of flesh eating nations reveal the highest rates for the three diseases mentioned, in marked contrast with nations that consume from 50 to 400% less meat per capita. The following list shows the exact comparison:

DEATHS PER 100,000 AMONG FLESH-EATING FOREIGNERS

Chronic Heart Bright’s Cancer. Disease. Disease.

Irish 166.6 381.2 410 German 151.9 231.5 212 English 140 207 209 Bohemian 246 237.4 255.7

DEATHS PER 100,000 AMONG NATIONALITIES NOTED FOR SMALL CONSUMPTION OF MEAT

Chronic Heart Bright’s Cancer. Disease. Disease.

Austro-Hungarian 151.5 190.7 131.2 Swedish 84.7 69.7 99.6 Polish 130 170 121 Italian 63.7 161 107.7

Another argument which the opponents of meat-eating bring forward, is based upon the fact that in eating flesh which contains blood, we consume a great deal of waste material and poisons from the body of the animal. When the blood flows from the heart outward to each organ of the body it is a life-stream containing life-giving oxygen and particles of fresh food material for the use of the tissues, but when it flows back it is freighted with the elements of disease and death, with poisonous substances which are the bi-products of organic activity, and which, if retained in the body for any length of time invariably cause disease. The rapidity with which the blood becomes impure and poisonous may be easily noted by winding a string about the finger, when the flesh will quickly turn a blue color. Animals die as men and women die, with their ailments within them, and if you eat of them you eat the products of their disease process. Tuberculosis is known to be one of the maladies sometimes transmitted by the use of flesh. Numerous epidemics of typhoid fever have been traced to the use of oysters.

THE PROTEID ARGUMENT

It had generally been assumed by physiologists that the great virtue of meat lay in the greater digestibility of its proteid matter. Recent experiment investigations, however, have shown that the vegetable proteids are as a rule not less digestible than those from animal sources. The vegetable proteids are often packed away and enveloped in cellulose or other material difficult of digestion, or are permeated with fats, as in some of the nuts; but modern methods of preparing grains for the market, and also the thorough cooking of them, remove this difficulty.

The deficiency of ordinary vegetable dietaries in proteids has been a ground for criticism by the opponents of this regimen. Since, however, the researches of Chittenden, Mendel, Metchnikoff, Dr. Folin, and others have shown us that we need much less proteid than the elder school of physiologists so long supposed, this objection loses its weight. And, furthermore, there are many nut foods which are even richer in proteids than cooked meats. Cooked meat contains 25% of proteids, while peanut butter contains 29%. The edible portion of walnuts contains 27%, and the edible portion of pine nuts 35%.

To sum up the argument in this matter it is our belief that modern science has demonstrated that excessive meat eating is dangerous, because of its high proteid content and its liability to germ infection; and, also, that we can obtain all the elements which meat contains from other kinds of food which are not open to the objections fairly to be made against the use of meat. Nevertheless, here, as elsewhere, it may be said that “Fletcherism,”—complete mastication—is again the key that unlocks the solution of this problem for many. Thorough mastication leads to the use of less meat; it also gives the germicidal saliva a chance to kill harmful germs; and it aids the digestive organs very materially. Eat meat—says the rational physiologist—if you feel you must, or if it is difficult to abandon its use, but be careful to chew it well.

It is true, to be sure, that the digestion of proteid is accomplished not by saliva, but by stomach juices, which would seem to be an argument in favor of bolting meat (as the dog does), but the mere maceration of the meat by the teeth, if nothing more, is a help to the stomach in its work of digestion.

X

THE CASE AGAINST STIMULANTS

The dominant note of the discussion that for years has been waged in scientific and medical circles as to the effect of alcohol on the human constitution has been, to the puzzled layman at any rate, the insistent, reiterated cry of the fundamental “mystery” of alcohol. Alcohol is poison! cries one school. It is not anything of the sort, being, as a matter of fact, a food! retorts the opposing school. Its use in health or its administration to patients sick of any ailment is hardly short of a crime, declares one leading physician. Tut! tut! alcohol in moderation does no harm, and it is invaluable in the treatment of many diseases! replies another. And so the arguments proceeded.

Summing up his views of the deliberations of the British Association for the Advancement of Science, recently held at Leicester, England, and which formed a storm center for the great alcohol debate, a noted chemist in London “Science,” said that we know how far the sun is, and can tell the weight of the earth, predict when the next comet may be expected, and give true answers to many other important questions, but we do not know “anything to speak of” on the subject of alcohol. As to the discussions that have waged at Leicester and elsewhere on the question of the medical use of alcohol, the general impression left on the world of laymen is that they all (the noted authorities) disagreed with one another more or less, and that nobody can declare with any scientific authority whether alcoholic liquor is good for us or bad for us.

We propose here to describe the work of one scientist who has made experiments which enable him to declare with authority that alcohol is injurious. This investigator is Charles E. Stewart, M. D., of the Battle Creek Sanitarium. He has closely studied the work of Sir Edward Wright, London, the discoverer of “Opsonins”; and his experiments were suggested by those of Wright. They led him to the discovery that alcohol has a harmful effect on the blood by lowering its supply of opsonins.

It has been demonstrated to the satisfaction of most students of Wright and Metchnikoff, and their allies, that the opsonins form one of the most valuable of the body’s defences against disease. And if Dr. Stewart has demonstrated that alcohol poisons the opsonins, it must be admitted that at last a positive and tangible proof has been brought forward of alcohol’s harmful qualities. What nourishes and strengthens the blood, helps the lifeforce within us; what weakens or poisons the blood, is an attack upon the very citadel of vitality. Alcohol, says Dr. Stewart, is such an enemy.

In such diseases as pneumonia and tuberculosis, the white cells, according to Wright, cannot effectually combat the germs unless there are plenty of opsonins present to aid them. Now, in treating pneumonia and tuberculosis, many practitioners encourage the use of alcohol. Dr. Stewart believed that alcohol was injurious. Having heard Sir W. Edward Wright’s lectures, he asked himself the question:

“Can the evil effects of alcohol be due to its lowering of the opsonic power of the blood?”

He instituted a series of experiments to determine, if possible, the facts in the case. He first of all administered to four persons who all their lives had been total abstainers, two ounces each of port wine. The normal opsonic power of each of these individuals had been determined as being 75 or above—that is to say, it was well above the point at which the opsonic power must be maintained in order that the white cell may do effective fighting. At the time when the subjects took the port wine, the first subject had a normal amount of opsonic power to resist the germ of tuberculosis which may be expressed by the term 1.13., and a normal power of resistance to the pus germ, which infects wounds, of 1.06. After drinking the wine, both those powers of resistance were lowered most perceptibly; the first to .85, and the second to .67. Similar results, in greater or less degree, followed in all other cases. The port wine decreased the power of the blood to make opsonic sauce for the white cells.

In a second series of experiments, two ounces of Scotch whisky were taken an hour apart; that is, the normal index was taken, and immediately afterwards an ounce of the Scotch whisky was taken, an hour later another ounce, and an hour after this the index was taken again. The results here were similar. For the germs of tuberculosis it was discovered that the opsonic power had dropped 10% and for the streptococci (or pus-forming) germs about 8%.

In another experiment where two ounces of sherry wine were used, the opsonic power for the germs of tuberculosis dropped 11% and for the streptococci 5%.

In another experiment where four ounces of champagne were taken, the opsonic power dropped 9% for the germs of tuberculosis and 19% for the streptococci germ. Many other experiments were performed, but they gave practically the same results. The opsonic power decreased in proportion to the amount of alcohol contained in the liquor.

Dr. Stewart carried on his experiments in the laboratory of the Battle Creek Sanitarium, with the assistance of Dr. A. W. Nelson. He reported his results to the American Society for the Study of Alcohol and Drug Neuroses:

“I realize that there are a great number of factors which influence the opsonic power of the blood, and that there is considerable variation in even what may be considered normal cases, but, notwithstanding these variations, there is a sufficient uniformity to enable us to make some very valuable deductions. I feel justified in concluding that alcohol has a marked influence in reducing the vital forces of the body, thereby greatly interfering with the natural power of the body to remedy ailments. Since Wright has shown that out of all comparison the most valuable asset in medicine lies in raising the anti-bacterial power of the blood, the adminstration of alcohol, which according to these experiments, is pro-bacterial, and as such a strong liability instead of an asset, should be eliminated from our therapeutics, at least so far as internal administration in infectious diseases is concerned.

“While only a comparatively few experiments have been made, the results obtained have been uniform, and justify, I believe, the preliminary report of it given to the medical profession and the public with the hope that it may encourage others to pursue the work further in this direction.

“Heretofore, when any statement was made to the effect that alcohol caused this or the other disease, or ailment, or harmful effect of any sort on the human constitution, the reply could be and was made that the case could not be proven; that there were always

circumstances which might be construed as showing that other factors besides alcohol influenced the situation. Now, however, I believe that we have opened up a line of investigation which will place the proofs against alcohol on a solid scientific basis by demonstrating its injurious effect on the blood, which is the life."

TEA AND COFFEE

In the same laboratory where Dr. Stewart placed his case against alcohol, experiments are being made which show in the same direct way that such drinks as tea and coffee also lower the opsonic power of the blood. Into the United States alone are imported more than one billion pounds, or five hundred thousand tons of tea and coffee each year. It is estimated that tea and coffee contain from three to six per cent. of poison. Therefore, more than fifteen thousand tons of poison, "so deadly that twenty grains might produce fatal results if administered to a full-grown man in a single dose"—in all more than ten billion deadly doses of poison, or, "fully six times as much as would be required to kill every man, woman and child on the face of the earth," are brought into this country every year, as component parts of substances which are commonly regarded as pleasant foodstuffs.

This is the case stated against coffee and tea in its broadest and most emphatic form. The opponents of the use of tea drinking term both tea and coffee "drugs." What is commonly thought to be the pleasantest property of both tea and coffee, namely, their ability to banish one's sense of fatigue, is regarded by the critics of the tea and coffee drinking habits as perhaps the most sufficient evidence of their poisonous character.

"No one would doubt for a moment," says one such critic, "the poisonous nature of a drug capable of producing irresistible drowsiness in a person who is not weary, as morphine would, for instance. Vice versa, the power of a drug to produce wakefulness in a person strongly inclined to sleep as the result of fatigue is equal evidence of its poisonous character. The sallow complexion common among women of the higher classes who have reached middle life, the almost universal nervousness among American women, and many common digestive disorders, and the increasing prevalence of nervous or sick headaches, afford to the experienced physician ample evidence of the toxic or poisonous character of tea and coffee."

Tea and coffee contain (in addition to caffeine) tannic acid, and various other volatile poisons, each of which produces characteristic harmful effects. The volatile oils give rise to nervous excitability, and after a time provoke serious nervous disorders. Caffeine is a narcotic, which has been shown to diminish the activity of the peptic glands—and thus seriously to interfere with the normal operation of the organs of digestion. The eminent physiologist, Wolfe, showed by experiments that three grains of caffeine—an amount that might easily be imbibed in an ordinary cup of tea or coffee—very substantially impairs the quality of the gastric juices, lessening their total acidity. Roberts' experiments showed that tea and coffee interfere with the action of the saliva upon the starch of the food, and at times may even wholly destroy its effect.

XI

DIET REFORM IN THE FAMILY

The reader is now familiar with the new ideas upon the subject of human nutrition. It is obvious, of course, that if these ideas should ever come into general acceptance, there would be enormous changes in the every-day habits of human beings. And we can well imagine that a person might be fully convinced of the soundness of all the arguments which have been advanced in this book, and yet shrink in dismay from the complications incidental to applying them.

We ourselves have faced these difficulties in many forms. We have wished to have two meals, and yet felt obliged to have three, because all our friends had them, and we did not wish to be hermits. We have wished to avoid meat, and yet have eaten it, because it was on the table, and we did not like to startle our hostess—and perhaps find ourselves involved in an argument about vegetarianism, in the course of which we had either to permit a good cause to go down into defeat, or else to tell facts about meat which would take away every one's appetite for meat, and for vegetables as well. But in the end, the desire for health has conquered all other motives with us, and we have broken with every trace of the old ways. It seemed to us that we would help and interest others if we gave some account of how the new ideas have worked out in practice, and the daily regimen of a family which adopts them.

This book is written in Bermuda, where the writers have been living in co-operation, along the lines worked out at Helicon Hall, only upon a much smaller scale. Their party consists of eight adults and three children—this including two governesses, a secretary, and a servant. They live in an isolated neighborhood, upon the waterfront. Most of the party sleep out of doors on the broad

verandas of the house, while the wide doors and windows of the other rooms afford ample ventilation. Daily sea-bathing is the habit of all of the group.

The married women of the party assume in turn the direction of our dietaries; that is to say, they choose the menus, and attend to the ordering of the food supplies. We eat but twice a day, and the menus are made up entirely of fruits, grains, nuts and vegetables, with the occasional use of eggs. We obtain from the Battle Creek Sanitarium a great number of the foods we use, availing ourselves of its splendidly managed food-department. The children eat three times a day, but their breakfasts are very light, consisting of orange juice and a fig or two, or perhaps a banana. The children have this light breakfast immediately after arising. At ten o'clock comes the principal meal of the day for the whole household. An effort is made to make this meal "well balanced"; that is to say, to have the proportion of proteids, carbohydrates and fats. There are usually not more than two, or at the most, three cooked dishes. Sometimes the main dish is a soup; sometimes it is baked or boiled macaroni with tomato dressing; sometimes it is bean or pea croquettes; sometimes it is scrambled eggs, or the yolks of hard boiled eggs.

We have a constant supply of fresh vegetables, the justly celebrated Bermuda onion; beets, turnips, egg plant, raw cabbage, potatoes, white and sweet, rice, hominy, green peas, tomatoes, and lettuce.

We have corn pones, corn bread, brown bread containing oatmeal, ordinary white bread, and oven toast—that is to say, slices of bread baked in the oven until it is brown all the way through. From Battle Creek we have malt honey, malted nuts, ripe olives, olive oil, fig and prune marmalades made without cane sugar, various crackers and grain preparations, and several other nut products. The Sanitarium health-chocolate, a sweet made without the use of cane sugar, and with chocolate divested of its caffeine, also appears on our table. We have eliminated dessert at dinner, having learned not only at Battle Creek, but in the sore school of experience, that the heterogeneous mixtures of cream or milk and cane sugar and various mushy stuffs, along with butter or lard, in the shape of pies and puddings and cakes, are extremely undesirable foods. We find the sweet, pure taste of malt honey an adequate and highly satisfactory substitute.

[Illustration: The Daily Swim]

Fruits rarely appear on the table at dinner, since we do not wish to mix them with vegetables. They make their appearance in great abundance at supper, which we have at five o'clock. At this meal we have various cooked fruits, such as prunes or apricots or baked or stewed apples; and of uncooked fruits, oranges, apples, figs, bananas, grapes, and whatever else the market affords. With these we have zweibach and common bread or crackers. At both meals appears Yogurt, an acidulous and agreeable beverage which gratefully checks thirst and in itself nourishes, and is also the vehicle whereby millions of beneficial germs are introduced into the body.

The work of preparing and serving these two meals is done by one person—and that person has time left to play tennis and go in swimming with the rest of us. The total cost of the food is less than thirty dollars a week; cooked and served, its cost is about three dollars and a quarter a week per person. In this connection it should be explained that Bermuda prices, for even the commonest things, are in excess of prices in New York. We pay five cents each for eggs and twelve cents a quart for milk. We have oranges by the barrel, but they come from California, or from Jamaica by way of New York. We have olive oil at four dollars a gallon, and sterilized butter at fifty cents a pound. And in addition the figures quoted include expressage and steamer charges, and ten per cent. duty as well. We mention these things for the light they throw upon the relative costs of the vegetarian and carnivorous life.

The reader will also wish to know about the health of a family living in this manner. When we came here all our children were half-sick from too long contact with cities, and we were not used to the climate, and so one of them caught a severe cold. With this exception there has not been a day's sickness among them, nor the remotest trace of an ailment. If we were to describe their looks the reader might attribute it to parental blindness, and so the proper plan seems to us to insert a picture of them, and let the reader come to his own conclusions.

For the guidance of any housewife who may wish to try our regimen, we give a few typical menus, and also recipes for some of the favorite dishes of our family. We are all hungry when mealtime comes in our household, and we enjoy the surprises of the menu with all the zest that we ever welcomed roast turkey and pumpkin pies in the old days. And this seems in some magical way to be true, not only of ourselves, but also of such guests as happen along. It is worth noting that three different persons, who have never before known or thought anything about vegetarianism, have stayed with us for periods of several months; and all of them have fallen into the ways of our household, have been well and strong, and untroubled by craving for meat—and in two cases have found, to their great dismay, that they were gaining in weight upon two "low proteid" meals a day!

The first of the tables which follow contains a typical menu for a week; and the second gives an extra list of dinners. The third shows what we do upon some special occasion; it was the banquet which we prepared for Mark Twain—only, alas, his physician had ordered him to be home by sundown, and he couldn't stay to partake of it.

Inasmuch as all people cannot change their meal hours in accordance with those we have suggested, we give these menus upon the basis of three meals a day, with the various food elements properly balanced. We have also included simple desserts, for the benefit of those who do not care to dispense with this feature. The menus in our own home are similar to these, with the exclusion of the breakfasts and the dessert.[1]

[1] Very good vegetarian cook books are those entitled "Science in the Kitchen," and "Healthful Cookery," both of them by Mrs. E. E. Kellogg, the wife of the superintendent of the Battle Creek Sanitarium. Some of the books which are listed in another place as being those which a student of the new art of health may read will also furnish many good recipes. The "Art of Living in Good Health," by Dr. Daniel S. Sager, will be found especially helpful in this regard. We give in the Appendix three simple menus of the Battle Creek Sanitarium. These menus have the food values indicated, and will be found very useful in giving a rough idea of the number of calories contained in ordinary foods.

MONDAY

Breakfast

Oranges Poached eggs Graham gems

Dinner

Lima beans, dried or fresh Baked potatoes Mixed nuts Whole wheat bread Lettuce salad Tapioca pudding

Supper

Oven toast brown bread Cottage cheese Apple sauce Almond cream Figs Bananas

TUESDAY

Breakfast

Grape fruit Corn meal mush with cream Buttered toast

Dinner

Baked macaroni Mixed nuts Brown bread Tomato salad with mayonnaise dressing Indian meal pudding

Supper

Zweibach Brown bread Ripe olives Stewed prunes Dates Bananas Hot malted nuts

WEDNESDAY

Breakfast

Baked apples and cream Omelet Pop overs

Dinner

Peas patties with tomato sauce Baked sweet potatoes White bread Boiled onions Baked custard

Supper

Oven toast Whole wheat bread Nut butter Stewed fruit Cottage cheese Apples Bananas

THURSDAY

Breakfast

Oranges Hominy with cream Currant puffs

Dinner

Bean and nut croquettes with cream sauce Baked egg plant Graham bread Boiled rice Dates with whipped cream

Supper

Oven toast Graham bread Honey Ripe olives Apple sauce Grapes Bananas

FRIDAY

Breakfast

Grapes Scrambled eggs Whole wheat gems

Dinner

Vegetable soup Assorted nuts Beet and lettuce salad with mayonnaise dressing Corn pones Cottage pudding

Supper

Golden maize crackers Graham bread Nut butter Canned fruit Bananas and apples

SATURDAY

Breakfast

Grape fruit Toasted corn flakes with cream Buttered toast Marmalade

Dinner

Baked beans Cabbage slaw Baked potatoes Mashed turnips Brown bread Baked apples with cream

Supper

Oven toast Brown bread Cottage cheese Sliced pineapple Bananas Figs

SUNDAY

Breakfast

Grapes Soft boiled eggs Corn meal gems Orange marmalade

Dinner

Pea and tomato soup Succotash Corn bread Potato salad Baked bananas Mixed nuts and raisins

Supper

Zweibach Oatmeal bread Malted nuts Ripe olives Canned fruits Bananas Dates

EXTRA DINNERS

Yolks hard boiled eggs Baked potatoes Beets Prune pudding Vegetable soup Cabbage salad Corn bread Baked custard

Scrambled eggs Baked lyonnaise potatoes Beet and lettuce salad Dates with whipped cream

Macaroni with tomato sauce Whole wheat gems Egg salad Apple tapioca pudding

Baked beans Tomato, chili sauce Mashed turnips Lettuce with French dressing Lemon jelly

Pea soup Corn pones Potato and onion salad Cabinet pudding

Peas patties with tomato sauce Mashed potatoes Carrots with butter sauce

Baked nuttolene with cream sauce Baked sweet potatoes Stewed tomatoes Baked apples and cream Lima beans (fresh or dried) Baked sweet potatoes Lettuce Corn pones Stuffed dates

Baked beans Lettuce Corn (canned or sweet) Nuts and raisins

RECIPES

Vegetable soup: Cut in dice three turnips, three carrots, three onions, three potatoes. Cover with water and simmer for thirty minutes. Cook one can of tomatoes, or one quart of fresh tomatoes, strain and thicken a little with flour. Add to vegetables and cook thirty minutes. Add butter and sprinkle with parsley.

Corn pones: Three cups corn meal, 1 heaping teaspoon salt, 1 tablespoon sugar, 1 heaping tablespoon butter. Add boiling water until meal is scalded, pat it into flat, thin cakes and bake three-quarters of an hour.

Mayonnaise dressing: Yolk of egg; add 1½ cups olive oil, drop by drop, stirring in one direction. Juice of two small lemons, 1 teaspoon salt.

Macaroni with tomatoes: Half package macaroni; drop into a kettle of boiling water. Boil vigorously for thirty minutes. To one can tomatoes add two onions chopped fine. Simmer until onions are done, then strain and thicken with flour. Put macaroni into colander and rinse with cold water. Add the tomato sauce and simmer gently for fifteen minutes. It is well to do this in double boiler to prevent burning.

Bean or pea soup without meat or pork: Soak two cups of split peas over night. In the morning slice and add two large onions and simmer for several hours. Strain.

Beans baked without pork: Use butter or nut butter instead.

Bean and nut croquettes: Cook dried beans until soft. Strain through colander to remove all skins. Add equal parts of walnut meat ground in chopper; season with salt and a little sage. Mix with beaten egg. Form into croquettes and bake until dry and nicely browned. Serve with tomato or cream sauce.

Baked egg plant: Boil egg plant until tender; pare and mash; mix with bread crumbs and eggs, and bake until nicely browned. A little finely chopped onions may be added if desired.

Peas cutlets: One cup pea pulp, one cup steamed rice, one grated onion, one-half teaspoon sage, one-half cup tomato juice, one-third cup browned flour. Mix together and mold in cakes two-thirds of an inch thick. Bake half an hour. Serve with tomato or cream sauce.

XII

BREATHING AND EXERCISE

We have devoted most of our space to the problems of nutrition, since nutrition is the most important factor in the question of how to keep in health. We wish now to speak of other matters, of great importance in the art of keeping well; these are breathing, bathing, and exercise.

Many people have lived for more than a month without food. You can go for days without water. But if you are deprived of air for but a few minutes, your death is certain. Sixteen to eighteen times a minute the normal person respires, one breath being taken for every four beats of the heart, the central engine of life. Each time you breathe, the amount of air which passes into the lungs is about twenty-five cubic inches; which represent, however, but a small part of the actual capacity of the lungs. The average man can take into the lungs with an ordinary inspiration one hundred or more cubic inches, and is able to force out an equal amount with an ordinary expiration. If you have striven your utmost to expel all the air possible from your lungs, there will still remain about one hundred cubic inches of air within them. The total lung capacity of the average man is about three hundred and twenty-five cubic inches, or nearly one and a half gallons of air.

THE INDISPENSABILITY OF OXYGEN

Sunlight is the basis of all life. It is sunlight which plants absorb, and which they transform into materials which go to make up the living tissues of all things. The place of breathing in the process of life is manifold. But its primary function is to make available for the body’s uses the sunlight, or energy, which is stored up in the food we eat. It does this by means of the oxygen which it contains,

and the purpose of breathing is to obtain from the air an adequate supply of oxygen. Oxygen is one of the essential materials required for the support of life. Without oxygen the whole life process would come to an end. From every breath that is taken into the body, about one and a quarter cubic inches of oxygen must be obtained by the body, to keep up the fire of life within us. You cannot burn a match, or your reading lamp in the evening, unless there is an adequate supply of oxygen; and even so does the body require this indispensable and all powerful element in order to maintain itself.

[Illustration: FRESH AIR IN BERMUDA]

We have noted the fact that of the myriads upon myriads of swarming cells which the blood contains, a large proportion are the oxygen-conveyers. When you take air into your lungs, these cells absorb the precious element, and rush with it to all parts of the body. After distributing the oxygen wherever it is needed, they pick up for the return journey to the lungs all manner of débris and gases—the poisons which are produced by the organs of the body as they carry on their work. As Metchnikoff has shown us, it is the accumulation of poisons produced by the activity of our various organs which, unless properly disposed of, or kept below excessive quantities, bring about premature old age, the majority of all diseases, and early death. The amount of poisons which the average person throws off from the body with a single breath, as has been shown by delicate laboratory experiments, is enough to contaminate and render unfit for breathing three cubic feet or three-quarters of a barrel of air. Assuming an average of twenty breaths per minute, which is the normal rate for breathing for adults, the amount of air each person contaminates per minute will be sixty cubic feet, or one cubic foot a second.

If you hold your breath for a minute, you will be conscious of an extremely unpleasant feeling, which is the way in which the body manifests its urgent need for oxygen. The need of ventilation is not merely the need of oxygen, however. There may be plenty of oxygen in the air of a room which has been closed for some time, and which has been breathed in and out of the lungs of the people in the room; the trouble is that this oxygen is unfit for breathing, being full of impurities thrown off by the bodies of these people.

HOW TO CALCULATE ROOM VENTILATION

Dr. Kellogg has supplied some exceedingly useful calculations of the degree of ventilation needed in rooms of various sizes. “Every one,” he says, “should become intelligent in relation to the matter of ventilation, and should appreciate its importance. Vast and sometimes irreparable injury frequently results from the confinement of several scores or hundreds of people in a school room, church or lecture room, without adequate means of removing the impurities thrown off from their lungs and bodies. The same air being breathed over and over becomes intensely charged with poisons which render the blood impure, lessen resistance and induce susceptibility to taking cold and to infection with germs of pneumonia, consumption and other infectious diseases which are always present in a very crowded audience room.

“Suppose, for example, a thousand persons are seated in a room forty feet in width, sixty in length, and fifteen in height; how long a time would elapse before the air of such a room would become unfit for further respiration? Remembering that each person spoils one foot of air every second, it is clear that one thousand cubic feet of air will be contaminated for every second that the room is occupied. To ascertain the number of seconds which would elapse before the entire air contained in the room will be contaminated, so that it is unfit for further breathing, we have only to divide the cubic contents of the room by one thousand. Multiplying, we have 60 × 40 × 15 equals 36,000, the number of cubic feet. This, divided by one thousand, gives thirty-six as the number of seconds. Thus it appears that with closed doors and windows breath poisoning of the audience would begin at the end of thirty-six seconds, or less than one minute. The condition of the air in such a room at the end of an hour cannot be adequately pictured in words, and yet hundreds of audiences are daily subjected to just such inhumane treatment through the ignorance or stupidity of architects, or the carelessness of janitors, or the criminal negligence of both.”

TUBERCULOSIS POINTS THE MORAL

No circumstance has been more successful in impressing the great importance of fresh air and adequate ventilation upon the public mind than the success which has attended the open air cure for consumption. This is a mode of treatment of comparatively recent adoption in America, but it is by this time generally recognized as really the only possible cure for tuberculosis. The mortality from this disease is greater than any except pneumonia; another disease that proper breathing habits will do much to avert. In America one person in every nine dies of tuberculosis; and of the deaths which occur between the ages of fifteen and thirty-five, one-third are due to the great white plague. We give these figures on the authority of Professor Irving Fisher of Yale, who is

Secretary of the New Haven AntiTuberculosis Association. His interest in this disease is that of one who has had it, and who has cured it by the open air treatment. Of the authors of this book, one has had an experience similar to Professor Fisher. There is nothing academic about this insistence on the need of fresh air and proper breathing habits; literally, and in the fullest degree, it is a question of life and death whether you shall breathe properly, and have good air to breathe, or whether you shall not.

HOW BREATHING AIDS THE BATTLE OF THE BLOOD

To return for a moment to the processes of breathing, we find that the act of inflating the lungs is a blood-pumping process as well. This blood-pumping process has a great effect upon the struggle of the white soldiers of the blood to maintain the body against the inroads of disease. Each time that the wall of the chest is elevated after the lungs have been emptied, a suction force is exerted upon the large veins which enter the chest, especially those which come in through the abdominal cavity. “At the same moment,” to quote Dr. Kellogg again, “the downward pressure of the diaphragm by which the liver, stomach, and other abdominal organs are compressed against the muscular walls of the abdomen, serves to force the blood from below upward, emptying the venous blood of the abdominal cavity into the chest, thus helping it toward the heart. The more tense and well developed the muscles of the abdominal wall and the stronger the muscles of respiration, the stronger will be this upward movement of the blood. When the abdominal muscles are weakened by improper dress, by corsets, tight lacing, or by wearing of belts or bands or by sedentary habits, especially sitting in a stooped position, the weakened muscles yield to the downward pressure of the diaphragm, thus neutralizing to a large degree the beneficial influence of this action. This condition is unquestionably a cause of chronic disease of the liver and stomach, inactive bowels, and possibly lays the foundation of cirrhosis of the liver, spleen, and other grave disorders of the abdominal region.”

It is very obvious how deep breathing will thus influence the vigor of the blood’s army of cells. Deep breathing forces the blood to rush into the lungs, there to be charged with oxygen. Without this oxygen the white cells die. Vigorous breathing also directly aids digestion, and promotes the absorption of food materials. Those who have slow digestion will find that breathing exercises will be of especial benefit. In ordinary breathing of a quiet person, the movements of the chest are so slight as to be scarcely noticeable, but when vigorous breathing is indulged in, the diaphragm as it moves up and down kneads the stomach and its contents and, very materially, assists the digestive organs.

HAVE FRESH AIR AT NIGHT

During sleeping hours the breathing movements are slighter and slower than when one is awake and active. It is necessary that the activity of the body should be lessened in order that rest may be secured; and yet the work of the liver, kidneys, and other organs which are engaged in throwing off poisons goes on continually; as does also the repairing work of the living cells, which are forever building up the parts of the body broken down by work or sickness. For some six to nine hours the body is thus occupied in resting and repairing itself, in order that on the next day it may respond like a living machine to the demand of the conscious mind. We should do all in our power to help on this recuperative process; and no way will be more effective than to sleep, out of doors, or with the head at a window, or at least in a well-ventilated room.

There are a great number of breathing exercises described in various books on the subject, but the best breathing exercise is natural breathing. If the head is kept erect, and the shoulders low so that the chest is upright; if breathing is carried on through the nostrils, and the habit of deep breathing carefully cultivated—there will be no need for special exercises, save in the case of invalids. The most effective of all breathing exercises is to run or walk rapidly, or walk up a hill, or up stairs, if these be in the open air, with the head well back. This exercise heightens the action of the lungs, and all parts of the body are flooded with fresh air.

HOW EXERCISE AIDS THE BATTLE OF THE BLOOD

The question of breathing properly is intimately bound up with the question of exercise. The best of all exercise is play. All games in the open air which a person takes part in for the love of them far surpass the cleverest and most scientific sets of rules which physiologists have ever evolved. Unconscious performance of all the functions of the body is the ideal of hygiene. Exercise aids the battle of life within us in a direct manner. Exercise breaks down worn out tissue, making room for new and healthy tissue. It increases the rate of oxidation or burning up of fuel within us, and this in its turn enables the body to get rid of waste of material. Exercise also increases the strength and endurance of the muscles and fibres.

When muscles become weak, they relax and allow various portions of the body to drop into positions which are not only ungraceful, but are decidedly injurious. When the muscles are not used and become flabby, the shoulders get rounded and drop forward

through the weakness of the muscles which are intended to hold them back in position. The ribs which form the framework of the chest not being properly sustained by the muscles attached to them, gradually fall inward, thus flattening the chest, and compressing the lungs. There is a very close connection between gracefulness of carriage and sound bodily health.

The person who lounges, or slouches, be it ever so picturesquely, does so at the expense of the body. Proper exercise will prevent these physical defects, and will remedy them in most persons who have not yet attained middle age. Even in advanced years, say the physiologists, much may be done to correct these physical deformities by properly directed and systematic exercises.

EXERCISES MAKE NEW BLOOD

Exercise has another most important task in supplying an adequate amount of blood to the bones of the body, in order that these bones may carry on their work of manufacturing fresh blood for the use of the body. Unless these bones are bathed with the already existing blood of the body, which carries to them oxygen and nourishment, the process of manufacturing new blood, which goes on within the marrow of the bones, would quickly cease. It has been demonstrated by science that muscular activity increases the blood flow through the muscles as many as six times.

Here, then, lies perhaps the first hope for supplying new blood to any body which has begun to deteriorate through the accumulation of poisons emanating from the large intestine, or from the other organs. Exercise will supply the blood-producing bone marrow with six times as much raw material to make new blood as a sedentary mode of life would produce, and at the same time this six-times-strengthened flood will wash out of the crevices of the bones and muscles and fibres the stored up poisons. For these purposes, the exercises which move the large muscle masses are the most helpful. Dr. Benton A. Colver, of the Battle Creek Sanitarium, to whom we are indebted for assistance in preparing this chapter, names the following exercises as being beneficial for this purpose:

Low knee bending, stretching and heel sinking, and heel raising; lying on the floor with the weight supported by toes and hands, and lowering and raising the body; raising the body by the arms, holding to a bar above the head; walking with a vigorous stride, and running and swimming.

Of all these exercises, swimming is theoretically the best, for the reason that it exercises equally all the muscle masses in the body, and requires the best balanced of all movements. Walking and running come next in the order of excellence, simply for the reason that they can be carried on best in the open air and without the bother that may accompany the performance of more formal exercises.

EXERCISES WHICH RETARD AUTO-INTOXICATION

Another way in which exercise directly helps the battle of the blood within us, is by assisting such organs of body-poison elimination as the spleen, the liver, and the portal system of veins. It is in these organs that the exhausted blood is broken up and cast off. The blood in these organs is loaded with broken down tissue and other waste material from the body, and is contaminated with gases and poisons. In the body of the person who leads a sedentary life a great volume of blood settles in these organs and is prematurely put out of use.

Proper exercises will empty this great tank of stagnant blood as easily as a sponge is emptied by the pressure of the hand. This passive blood, having access to all the organs of digestion, is largely responsible for the supply of inferior digestive juices, and thus is a leading factor in indigestion, loss of appetite, and such diseases as catarrh of the stomach and bowels. If, however, this blood is pumped on as it should be to the heart and lungs, there to be cleansed, the fresh blood rushes in to fill its place, armed by the activity of the lungs with its life-giving ammunition of oxygen.

By persistently keeping up this emptying and filling of the portal veins, and of the spleen and liver, the old cinders left from the oxidation of food are washed away, new digestive juices are formed, and the whole tone of the body is improved. For such purposes such exercises as the following are extremely valuable:

Stand erect and, with the hands on hips, bend the trunk forward, backward, and sideward, keeping the legs stiff. Trunk rotation, performed by bending forward and then describing as large a circle as possible with the head thrown first to the right and then to the left, and bending the trunk backward as far as possible when that segment of the arc is reached; lying on the back and raising first the head, second the feet, with bent knees, and third, the feet with straight legs. These exercises stretch the diaphragm against the liver and portal vein, and thus squeeze out the blood from these organs and send it back to the heart and lungs.

EXERCISES WHICH PROMOTE DEEP BREATHING

A third manner in which exercise directly assists the battle of the blood is by increasing heart action and deep breathing. Exercises which accomplish these functions insure an abundant supply of oxygen to the blood and the tissues. In this manner, more heat will be produced in the active tissues, and the blood current will carry this beneficial glow of heat to the most distant parts. This toning up of the “heating system” will be evidenced by the appearance of perspiration. When skin and lung activity are thus increased, the accumulated wastes of the body are quickly eliminated.

[Illustration: OUTDOOR EXERCISE.]

The person who takes vigorous exercise in the open air such as playing games like tennis or golf, or who walks vigorously, will have no need for formal breathing exercises. For those, however, who cannot readily obtain outdoor exercises the natural way, the following chest movements and breathing exercises are recommended. They should be taken with the body free from tight clothing, and either in the open air or a well-ventilated room. First, raise the hands above the head as far as they can reach, and then bring them forward and upward several times, and then upward and downward on the side of the head, inhaling on the uplifting of the arms, exhaling on the sinking of the arms. When the arms are lifted above the head, opportunity is given for the air inhaled to reach the upper part of the lungs, parts which in the sedentary person are very rarely used, and where usually the germs of tuberculosis begin their evil work. Arm extension forward, breathing deeply with arms carried sideward and backward, at shoulder height. If those who exercise in their rooms will be careful to breathe only through the nose and will keep the head erect, they will find that the performance of almost any set of exercises will serve also as breathing exercises, since they will increase lung activity.

XIII

BATHING AND CLEANLINESS

The soldiers of the body which carry on for us the battle against disease, old age, and death, have as great and as constant a need of water as do the human soldiers, part of whose equipment is always the indispensable canteen. Water is needed by the body in many ways, but it is especially required by the blood. Water is the solvent in which float the white and red corpuscles of the blood, and the many nutritive elements which the blood carries through the body, and the particles of waste material which it bears to the lungs to be burnt up, or to the other excretory organs to be ejected. By the aid of water, the minute particles of food which are broken up and transformed by the chemical processes of the body are conveyed to the most distant fibre of the intricate human mechanism, wherever repair or new growth is required. No other element of nature could so well carry on this function as water. It is so limpid and mobile that it can move through the most delicate and intricate network of veins, and can find its way by osmosis or percolation into such parts as are inaccessible by openings.

The human body is constantly throwing off water. A large portion is lost by evaporation from the skin, upon which it is poured out by millions of what might be termed little sewer pipes or sweat ducts, for the purpose of washing away impurities from the system. The kidneys remove a considerable quantity, bearing with it poisonous elements in solution, the product of various vital activities. In other ways water is removed from the body, to the amount of about five pints in twenty-four hours. This loss must be made good in order that the requisite fluidity of the blood shall be maintained; and the need of the body is expressed by thirst. Beverages which contain other substances, as flavor, or as part of some mixed drink, are useful as thirst quenchers just in proportion to the amount of water which they contain.

Physiologists point to the evaporation of water from the surface of the human body as being one of the most perfect adaptations of means to ends exhibited in the whole circle of life. The vital activities of the body occasion the constant production of heat. At times the heat is greater than is needed, and would destroy the vitality of certain tissues if it were not speedily conducted away, just as too much heat in a stove would melt the iron of the stove. The evaporation of water from the skin accomplishes this heat dispersal. When external heat is great, perspiration in the normal, healthy person is more active than when external heat is less than that in the body, and, by this provision of Nature, the temperature of the body is maintained at about 100° Fahrenheit under all circumstances, and thus man is enabled to exist under such great extremes of heat and cold as are found in nature.

There are numerous other ways in which water is essential to the process of life within us. The free drinking of water greatly favors the elimination from the system of the products of waste. It hastens tissue change, and encourages the assimilation of food. And apart from its use internally, it has also a very great value as a means of applying heat to or abstracting it from the body for

remedial purposes, to say nothing of the functions it performs as a cleansing agent. Of late years the value of water in therapeutics has become generally recognized by the medical profession, and all over the world its use as an active agent has increased. Indeed, in the view of some physiologists, ordinary pure cold water is by far the most powerful and useful of all known healing agencies. It heals not by any strange or occult power, but by co-operating with the natural forces of the body, by aiding to the utmost those physiological processes by means of which the body sustains itself in health, and resists the encroachments of disease by the means of its bodyguard of blood cells, and by maintaining at its high pitch its innate vital resistance. When the Austrian Priessnitz first began the use of water in his mountain village a century ago, the world believed that the wonderful cures he wrought were accomplished by mystical charms or incantations by which he was supposed to communicate to the water its healing power. Modern science, however, has revealed the secret of water's potency as a curative agent, and hydrotherapy, or curing by water, is now as well recognized as almost any other branch of medical science.

THE VALUE OF BATHING

The daily cold bath is one of the best ways of keeping the doctor at a distance. Cold water has the property of increasing vital work of all kinds. When it is applied to the skin "impulses are sent inward that awaken every organ of the body," says Kellogg. Let us see what takes place: when a person dips his body into cold water, as in sea bathing, or when he steps into the bath at home, the first thing he does, which in fact he finds himself doing involuntarily, is to draw in a deep breath.

"Oooh-h-h!" he says, but he says it with an indrawing breath. The lungs swell out, the heart begins to pound away with unusually increased vigor and strength, and every part of the system is stimulated. Cold bathing and deep breathing are two valuable things which go inseparably together. The deep breathing increases lung activity, and the lungs bring in more oxygen; the heart circulates the blood with greater force, and hence more and better blood is carried to every tissue of the body. The result is a stirring up of the bodily forces, and a distribution throughout the system of a larger amount of highly vitalized and oxygenated blood.

It has been shown definitely that cold bathing increases enormously the number of white blood corpuscles in the blood. Whether this result is accomplished by the birth of new cells, or by the calling forward of cells from remote parts of the body into the general stream of the blood, is not generally known; but the fact remains that counts of the blood cells taken just before and just after the body has been stimulated by cold water show a decided increase in the army of the warrior cells.

The benefit of sea bathing comes not from the salt in the air or in the water, as some people suppose, but simply from the cold water. The reaction from the dip into the cold water, which is brought about by the blood rushing to the surface to supply the heat which has been taken from it by the application of the water, is one of the most valuable of all curative processes. It is this reaction that sends the blood cells scurrying actively throughout the whole fortress of the body.

HOW COLD BATHING AIDS NUTRITION

Another way in which the application of cold water promotes the functions of life is by the stimulation of the secretion of gastric juice which it accomplishes. It thus helps on actively the digestive processes by which food is absorbed and taken into the blood. The liver and the salivary glands are stimulated in the same way.

When applied to the face, cold water stirs up the flagging energies of the brain, by invigorating the blood. A dash of cold water upon the chest produces a stimulation of all the bodily forces, which a tired person will find more valuable than any pick-me-up or tonic or cup of tea, or nip of whisky or other alleged stimulant could possibly be. Applied over the heart, this organ is made to beat with greater steadiness and vigor. Application to the stomach causes increased production of pepsin and acid or gastric juices. Over the bowels it stimulates intestinal activity; over the loins it increases the action of the kidneys. A cold compress, or a douch over the liver will cause increased liver activity. Every organ in the interior of the body may be thus aroused to increased activity by a simple application of cold water upon the skin overlying the organ, for thus a rush of blood will be caused to that particular portion. It is necessary that the application should be brief, three or four seconds to as many minutes. These short cold applications of water to the skin will increase immediately the activity of any sluggish part, or of any organ whose function we wish to increase as a means of aiding the body in its battle against the causes of disease.

The whole nervous system derives benefit from the stimulation of brief cold baths. This is one of the most valuable functions of water. Hydrotherapy has come to be a most valuable adjunct to the treatment of all nervous diseases. A slow stomach may be wakened up and set to doing effective work by a general cold bath taken daily, or by a local application of cold water. A cold water bag over the stomach for half an hour just before meal time is a wonderful appetite awakener, which may be used by persons

whose circumstances preclude them from the general cold bath and the exercises which cause a natural desire for food.

The best of all prescriptions for cold feet is to stand in very cold water a half inch deep and rub one foot with the other in alternation for five minutes. Hydrotherapy is the principal curative agent employed in the great Battle Creek Sanitarium, and its branches throughout the world, and in his book “Rational Hydrotherapy,” Dr. Kellogg has presented in a shape that makes the knowledge available to everybody the modes of treatment which may be employed at home. “A good way,” says Dr. Kellogg, upon whom we draw for information in the preparation of this chapter, “is to stand in the bath tub with the cold water faucet open and the plug out.” It will not be long before the feet will be red and will fairly burn with the afflux of fresh, warm blood which will rush to the feet.

Hot water can be used in conjunction with cold water, since heat tends to lessen vital work, and so heat may be employed when it is desired to diminish organic activity. Pain is one direct evidence of excessive activity. Heat is nature’s great remedy for internal pain. Heat cuts off the influence of cold and at the same time diverts the blood to the surface of the body. Cold, on the contrary, usually increases pain when the seat of it is some internal organ. Sometimes heat and cold are applied at the same time, as for a toothache, for instance, when a hot fomentation is applied to the cheek and an ice bag to the neck under the jaw. Pain in the pelvis is almost always relieved by a very hot foot bath or leg bath, which relieves the congestion by diverting the blood into the legs, and thus removes the condition which was responsible for the pain.

THE CARE OF THE TEETH

It appears to be a fact that in the United States the profession of dentistry, both mechanical and medical, has been carried to its highest point. No doubt Americans will cheerfully assure themselves that American brains and “bustle” are responsible for this condition. But the truth can not be quite so comforting; the great development of dentistry in this country must be due to the demand for it; and the demand for it evidences a state of affairs that is far from reassuring.

So rapid has been the increase of degeneration of the teeth in modern times, that many physiologists have seriously asked the question, “Will the American race become toothless?” To-day, while artificial teeth are manufactured from such a variety of substances and sold at such a variety of prices, it would seem that Americans are becoming a race of “store teeth” men and women.

As with all other branches of hygiene, dentistry is now beginning to discover the ideal of _prevention_; recognizing that the sanitary care of the mouth is a more important object that the most cunning imitation of teeth, or the most ingenious masterpieces in bridge and crown work. Under the leadership of a man who will be recognized in the future as a pioneer in the cause of health, Dr. D. D. Smith, of Philadelphia, a large and rapidly growing body of dentists have formed what is termed the Prophylactic School, the development of which will result not merely in the prevention of a great deal of disease of the teeth and mouth, but of all the body. Physicians in general, and even most dentists, have only begun to recognize the part which the mouth plays in the causation of diseases.

At the present time, there are, roughly speaking, about 14,000 dentists in the United States, who annually extract twenty million teeth, manufacture and insert three million artificial teeth, and hammer into the cavities of diseased teeth at least three tons of pure gold, to say nothing about the many tons of mercury, tin, and other metals employed in fillings. When the principles of the Prophylactic School spread, it is safe to say that while the importance of the dentist will become even more generally recognized than it is to-day, nevertheless he will pull fewer teeth, and use less gold and other metals. The principle upon which Dr. Smith, and his rapidly growing band of followers, build their work, is an intelligent recognition of the fact that there are in the human mouth to-day, as has been the condition through all the centuries, highly malignant features of general infection and causes of numerous diseases which until now have been wholly unperceived and neglected. The ordinary physician tells his patient to poke out his tongue, when he looks for an index to that patient’s general condition of health, but he does not look above or below or around or about the tongue, where, in a great number of cases he might find not merely the symptoms but the cause of his patient’s ailment.

“THE VESTIBULE OF LIFE”

To show some of the common mouth conditions that make it almost an ideal medium for bacterial culture, we quote the following paragraph from Dr. Smith, adding the fact that his statement is one with which all up-to-date physicians concur:

“The mouth, with its large extent of dentate surface, becomes quickly infested and infected with all manner of bacterial formations, decomposing particles of food, stagnant, septic matter from saliva, mucous and sputum, not infrequently with pus exudations from

irritated and inflamed gum margins, gaseous emanations from decaying teeth and putrescent pulp tissue, salivary calculus (tartar), nicotine, and the chemical toxins, or poisons, of decomposition which result from a mixing of mouth secretions, excretions and food remains in a temperature constantly maintained at the high normal of ninety-eight degrees Fahrenheit. While this may seem a formidable array, it fails to prevent any of the sources of infection connected with untreated teeth; and incredible as it may appear, these conditions are found not in the lower classes alone, but in general mouth conditions in high and low born, fastidious and boor, king and peasant."

"Try to estimate the amount of poisonous products that would be generated if such a surface were smeared over with the various foods from the dining table, and these allowed to decompose," says Dr. Alfred C. Fones,[2] "and a fair idea may be obtained of the amount of decomposition that is taking place in unsanitary mouths. Nor is this simile forceful enough, for the food in the mouth is in one of the most favorable environments known for the activity and virulency of germ life, so that the products generated would be far more numerous, more poisonous and irritating in every action, than such products from food decomposing in the open air."

[2] In his essay "Clean Methods, The First Law of Hygiene."

HOW MOUTH INFECTION SPREADS

Mouth infection, due to the teeth, sees its most critical period during that of childhood and early youth, a period in which the mouth under present conditions is almost entirely without intelligent care. Children's mouths, says Dr. Smith, are frequently veritable crucibles in which are generated chemical agents and compounds highly detrimental to the teeth themselves, and not less to the general health of the child. The poisons arising from decaying food particles and decaying teeth themselves, vitiated salivary and mucous secretions, germ life upon the teeth and gums, and breaths loaded with emanations from stagnant septic material, all with the high temperature of ninety-eight degrees, insinuate into the general circulation of the blood a constantly increasing infection, which will later on find expression in many diseased conditions, and often in chronic and fatal disorders. It may appear, as it commonly does, in stomach or kidneys, in lungs or nervous system, in heart, brain, or skin, in any organ or tissue, indeed, to which mouth toxins are directly or indirectly conveyed. Experience has shown that it is not only possible, but entirely practicable to arrest and prevent teeth diseases in the mouths of children, and at the same time to keep the mouth aseptic or free from germ life.

Not only does an infected mouth work havoc to the body of which it is the vestibule, but it spreads disease about it. The original experiments of Koninger have shown that in a room where there is no current of air perceptible, a person coughing or sneezing can scatter germs to a distance of more than twenty-two feet. They are conveyed through the air by means of little droplets of saliva. These globules are microscopic balloons, having a bubble of air in the center, and remain in suspension but a short time. Ordinary breathing will scatter these droplets to a considerable distance, but, of course, their germ-carrying capabilities are most marked during coughing and sneezing. The more microbes the mouth contains the greater the danger of infection. Washing the mouth has the effect of decreasing the microbes of such diseases as diphtheria and consumption, and other bacilli susceptible of being scattered abroad in these salivary droplets. Placing the hand or a handkerchief over the mouth prevents the emanation of droplets charged with bacilli. So well is this fact of droplet germ infection recognized, that in many operating rooms no one present is allowed to speak during operations. Chronic headaches, neurasthenia, constipation, coughs and colds, and many other grave troubles, have all been helped and many times cured by "oral prophylaxsis" or proper mouth treatment.

The practical application of the discoveries and recommendations of the new school of dentists can be expressed very simply and briefly, and if followed out, will undoubtedly prove of tremendous service to the white cells in the battle of the blood. It must be remembered that proper mastication of food, which we have seen to be a leading principle of the new hygiene, cannot be carried out unless you have a good and healthy mouth. Five brushings a day at home is the ideal and proper care for every mouth, for those who eat through the ordinary routine of three meals a day. The first thing in the morning the teeth should be thoroughly brushed with tepid water to remove the decomposed mucous and saliva produced in the mouth during sleep. After eating the teeth should be cleansed with the help of a dentifrice. The thorough removal of grease is a chemical process, not to be accomplished by mere brushing, and therefore requires a solvent such as is contained in a good dentifrice. Such duties soon become habits; and if they are based upon common-sense, the health which they will bring will more than compensate for the trouble involved.

XIV

A UNIVERSITY OF HEALTH

There have been frequent references in this book to the Battle Creek Sanitarium, and to Dr. J. H. Kellogg, its superintendent. We have written here of the art of staying well, but many people are sick, and are in need of special advice and assistance; to such we believe that we can do no greater service than to tell them of this Sanitarium and its work.

The institution is not a commercial one; its founder is one of the great humanitarians of the time, as well as one of the great scientists. None of its thousand odd men and women workers receive more than a bare living for their services, and the institution is legally so constituted that all its profits must be turned into the work. Therefore, we hold it to be a public duty to spread as widely as possible the facts relating to it. Mr. Horace Fletcher has called Battle Creek the “Mecca of Health.” More aptly still, the Sanitarium has been named a “University of Health”; and no image could be more essentially true.

[Illustration: DR. J. H. KELLOGG, Of the Battle Creek Sanitarium.]

For, while the people at Battle Creek realize that the record of the institution for more than forty years in curing sick people is one to which they may point with pride, yet in their view this good work is but a trivial thing in comparison with their principal object, which is the conversion of those who come to them to be cured, into home teachers and missionaries of the truths of right living. It is wonderful to observe to what a great extent success has already rewarded their efforts, to see the signs which indicate the growth of public interest in their work.

Dr. Kellogg took charge of the institution which is now known as The Battle Creek Sanitarium thirty-two years ago. The institution at that time was a small two-story building, known as a water-cure or health institute, with three or four cottages and twelve patients. With the changing of the name and management, and the application of scientific methods, a new era of prosperity began, and the work has steadily progressed ever since.

The Battle Creek Sanitarium was the first attempt to assemble in one place all rational means of treating disease in combination with the regulation of diet and habits of life, and giving special emphasis to physiologic or natural methods of cure. The institution has for many years been recognized as the leading establishment of the sort in the world.

From the beginning, the Sanitarium has been non-sectarian in character. Although a deeply religious spirit pervades the place, the institution is not and never has been under the control of any denomination. For many years it was closely affiliated with the Seventh-day Adventist denomination, because of the preponderance of persons belonging to this denomination among its managers and employees. For years, however, this affiliation has ceased to exist.

The institution is non-dividend paying. That is, it is a strictly altruistic or philanthropic enterprise. The charter which it received from the State requires that its earnings shall be devoted to the development of the enterprise and the maintenance of its charities. Dr. Kellogg receives no compensation for his labors in connection with the institution, and the thirty or forty physicians and business managers who are associated with him in his work likewise accept very meager compensation for their labors. Dr. Kellogg has for many years received a liberal income from the sale of his books, foods, and from his various inventions, but the income from these sources, as well as from the institution itself, has been devoted to the carrying forward of the humanitarian work to which he has devoted his life. The Haskell Home for Orphans, The Bethesda Rescue Home, the Life Boat Mission in Chicago, The American Medical Missionary College, and other charitable and philanthropic enterprises are allied enterprises which have grown out of the work which began at the Battle Creek Sanitarium.

The institution has never been endowed, and therefore, if the work was to grow, it was necessary to make money. The authors of this book have seen and read the legal documents by which Dr. Kellogg turned over to the American Missionary Association nearly everything of which he was possessed. The value of his work as a surgeon, estimated at prevailing rates for such work, would be at least fifty to sixty thousand dollars yearly. He touches not a cent of this money, nor does he touch his salary as superintendent—which he himself placed at the figure of twelve hundred dollars. There are many other physicians connected with the institution who, as specialists in New York or Chicago, would be in receipt of large incomes, but they are as content as is Dr. Kellogg to accept a bare pittance, finding their joy in the work they are doing.[3]

[3] The reader must be warned that there are many charlatans and shrewd business men who have taken advantage of the work of Dr. Kellogg and of the prestige of the name “Battle Creek.”

The energy displayed by the faculty and staff of the University of Health in carrying on their work is nothing less than astonishing. During one week when the writers were at the Sanitarium, there were more than a thousand patients all told, including the non-paying ones. There are many days when Dr. Kellogg operates from early in the morning until late at night, having very many

highly difficult and dangerous operations to perform, for he is well known as a surgeon. After such a long day in the operating room, without a break for food or rest, he will give one of his lectures to the patients, or go the rounds of the wards, winding up the day by attending to a mass of business or writing or studying in his laboratories. He works continually, day in and day out, for eighteen hours a day; and this he has done for the past thirty-five years or so. He wrote one bulky book containing much technical and scientific matter in ten days, using three or four stenographers, and working in stretches of twenty hours at a time. He has never taken a holiday. All of his many journeys abroad or in this country are on matters connected with his mission in life; and while on his journeys he is continually writing or studying, and carrying on the direction of his multitudinous affairs by letter or telegraph. Yet to-day, at the age of fifty-five, he shows no signs of diminution of energy; no signs of nervous breakdown, or of the ailments which bring thousands of business men and women to him for treatment.

He himself thinks that there is nothing very remarkable in all this. He attributes it to his abstention from meat, from tea and coffee, alcohol and tobacco. He never eats more than one “hearty” meal a day; his second meal, when he takes one, consisting of a little fruit. His sole regret is that during the first fourteen or fifteen years of his life he ate meat. He believes that any child, if it begin right, can, when it grows up, do all that he is doing.

“I was,” he said to a friend, “a puny, undersized, ailing child; born when my father was more than fifty. It was the accepted opinion that I would not live to be a man which I fully believed. I had an appetite for knowledge and resolved that since I was to die early I must study and work very hard in order to accomplish a little something before I died. So I would study until one to three o’clock in the morning; then rise at six. From the age of ten I have fully supported myself. All this deliberate stealing of time from sleep resulted in a permanent stunting of my growth. And as I went on in life, I kept up the same habits of night work. And yet, I have only once been troubled by an illness; which came upon me a few years ago as a result of overwork. But which I got rid of; and now I am in better bodily condition than I was twenty-five years ago. But I was not handicapped by a great number of things that are bars to other workers, over which they stumble. I have slept when I could in the open air; I have drawn from air, water, light, heat, and proper exercise, the benefits that inhere in them; and I have nourished my body on wholesome foods. I mention these points with insistence—these points that seem so freakish to many people—simply because to me they are fundamental points in the physiologic, or natural, way of healing and of living.”

Dr. Kellogg publishes a big magazine of large circulation named _Good Health_; and in this he teaches that health is not a mere negation of ailments—a state of being free from rheumatism, or consumption, or biliousness, or any other of the “thousand natural shocks that flesh is heir to”—but that it is being wholesome, happy, sane, complete, a unit—a man or woman eating, drinking, sleeping, working, playing, functioning in all parts as naturally, as inevitably, as easily and as unconsciously, as a flower grows.

One of the writers has told of his experience many years ago, when he went to a physician and requested to be helped in keeping well. He went to Battle Creek Sanitarium on account of the illness of his wife, and when one of the physicians proposed to him that he himself undergo the treatments, he answered (having in mind this earlier experience, and of the doubts it had bred in him), “There is nothing the matter with me at present that I know of.” The answer of the Sanitarium physician was, “The less there is the matter with you the better, from our point of view.” And so he realized that at last he had found a place where his own idea of health-preservation was understood.

He accepted joyfully the offer to assist him in getting a scientific understanding of his own bodily condition. A drop of his blood was taken and analyzed, microscopically and chemically. He went to the diet table, and for three days ate precisely measured quantities of specified foods; during the period all his excretions were weighed and analyzed and examined under the microscope. A thorough physical examination was made, and also a series of tests, upon a machine invented by Dr. Kellogg, to register the strength of each group of muscles of the body. The results of all these examinations were presented to him in an elaborate set of reports and charts, together with a prescription for treatments, diet and exercise. He had stated that there was nothing the matter with him, so far as he knew. He found that anaerobes—the dangerous bacterial inhabitants of the intestinal tract—numbered something over four billion to the gram of intestinal contents—a gram being about a thirtieth part of an ounce. During the six weeks of his stay at the Sanitarium the more important of these tests were repeated weekly; and when he left, the number of anaerobes had been reduced nearly ninety per cent.

Dr. Kellogg terms the system of treatment employed by the Sanitarium the Physiologic Method, and he writes of it as follows:

“The Physiologic Method consists in the treatment of the sick by natural, physical, or physiologic means scientifically applied.

“The haphazard or empirical use of water, electricity, Swedish movements, and allied measures is not the Physiologic Method. It is no method at all. It is empiricism, at best; at its worst, it is quackery. The application of the Physiologic Method requires much more than simply a knowledge of the technique of baths, electricity, movements, etc. It requires a thorough knowledge of physiology, and an intelligent grasp of all the resources of modern medical science. For, while the Physiologic Method depends for its curative effects upon those natural agencies which are the means of preserving health, and which may be relied upon to prevent disease as well as to cure, it recognizes and employs as supplementary remedies, all rational means which have by experience been proved to be effective.

“The Physiologic Method concerns itself first of all with causes. In the case of chronic maladies, these will generally be found in erroneous habits of life, which, through long operation, have resulted in depreciating the vital forces of the body and so deranging the bodily functions that the natural defenses have been finally broken down and morbid conditions have been established.

“Chronic disease is like a fire in the walls of a house which has slowly worked its way from the foundation upward, until the flames have burst out through the roof. The appearance of the flame is the first outward indication of the mischief which has been going on; but it is not the beginning. It is rather the end of the destructive process.

“The Physiologic Method does not undertake to cure disease, but people who are diseased. It recognizes the disease process as an effort on the part of the body to recover normal conditions,—a struggle on the part of the vital forces to maintain life under abnormal conditions and to restore vital equilibrium.

“At the outset of his course of treatment, the patient is instructed that his recovery will depend very largely upon himself; that the curative power does not reside in the doctor or in the treatment, but is a vital force operating within the patient himself. The Physiologic Method is based upon this fact. [Illustration: A GROUP AT THE BATTLE CREEK SANITARIUM (DR. KELLOGG ON THE RIGHT).]

“So the treatment of a patient consists, first of all, in the exact regulation of all his habits of life, and the establishment of wholesome conditions. The simple life and return to Nature are the ideals constantly held up before him. He must work out his own salvation; he must ‘cease to do evil and learn to do well’; he must cease to sow seeds of disease, and by every means in his power cultivate health.”

XV

HEALTH REFORM AND THE COMMITTEE OF ONE HUNDRED

We have set forth the underlying principles of the new art of health; and we have shown how these principles may be applied by individuals, and how they have been formulated and taught at the great University of Health at Battle Creek. It remains to give an account of a great national movement which has for its aim the spreading of a knowledge of the new hygiene in a semi-political way, a circumstance which to our minds proves that not only this nation but the whole of modern civilization is on the eve of a great revolution in its habits of living, and that this revolution will have for its rallying cry the word “Knowledge.” And more especially, “Knowledge of Our Bodies, and of How to Care for Them.”

The state of ignorance of the majority of people concerning the workings of their own bodies and the way to take care of them is to-day one of the greatest barriers to human progress. Few people realize that they ought to care for their bodies; or that they ought to know about their bodies until they are actually broken down. Men use their intelligence more aptly elsewhere; but all progress in other directions, in the arts and crafts and the labors of modern industry, will go for nothing if we do not learn to apply our intelligence to the matter of health.

More and more does the need for knowledge press home upon us. It is impossible for the race to survive unless that knowledge is spread. Our ancestors, it is true, knew less of their bodily make-up and bodily care than we do, but our ancestors did not need it so much. They were country dwellers, and people of the open air; they were not slaves of machinery and of office routine.

Dr. J. Pease Norton, Assistant Professor of Political Economy at Yale University, recently read before the American Association for the Advancement of Science, a paper which vividly summed up the situation which confronts us. He said:

“There are four great wastes to-day, the more lamentable because they are unnecessary. They are preventable death, preventable sickness, preventable conditions of low physical and mental efficiency, and preventable ignorance. The magnitude of these wastes

is testified to by experts competent to judge. They fall like the shades of night over the whole human race, blotting out its fairest years of happiness.

“The facts are cold and bare—one million, five hundred thousand persons must die in the United States during the next twelve months; equivalent to four million, two hundred thousand persons will be constantly sick; over five million homes, consisting of twenty-five million persons, will be made more or less wretched by mortality and morbidity.

“We look with horror on the black pages of the Middle Ages. The black waste was but a passing cloud compared with the white waste visitation. Of people living to-day, over eight million will die of tuberculosis, and the federal government does not raise a hand to help them.

“THE NEGLECT OF HEALTH A NATIONAL EVIL”

“The Department of Agriculture spends seven million dollars on plant health and animal health every year, but, with the exception of the splendid work done by Doctors Wiley, Atwater, and Benedict, Congress does not directly appropriate one cent for promoting the physical well-being of babies. Thousands have been expended in stamping out cholera among swine, but not one dollar was ever voted for eradicating pneumonia among human beings. Hundreds of thousands are consumed in saving the lives of elm trees from the attacks of beetles; in warning farmers against blights affecting potato plants; the importing Sicilian bugs to fertilize fig blossoms in California; in ostracizing various species of weeds from the ranks of the useful plants, and in exterminating parasitic growths that prey on fruit trees. In fact, the Department of Agriculture has expended during the last ten years over forty-sixmillions of dollars. But not a wheel of the official machinery at Washington was ever set in motion for the alleviation or cure of diseases of the heart or kidneys, which will carry off over six millions of our entire population. Eight millions will perish of pneumonia, and the entire event is accepted by the American people with a resignation equal to that of the Hindoo, who, in the midst of indescribable filth, calmly awaits the day of cholera.

“During the next census period more than six million infants under two years of age will end their little spans of life while mothers sit by and watch in utter helplessness. And yet this number could probably be decreased by as much as half. But nothing is done.

“In the United States alone, of the eighty millions living to-day, all must die, after having lived, say a little more than three billion, two hundred million years of life, on the average slightly more than twoscore years. Of these years, one billion, six hundred million, represent the unproductive years of childhood and training.

“Consider that the burden of the unproductive years on the productive years is 20-20, or say 100 per cent. Could the average length of life be increased to sixty years, say to forty-eight billion years lived by eighty millions of people, the burden of the unproductive years would fall to 50 per cent. In the judgment of men competent to hold opinions, this is not impossible.”

It was the reading of this paper, which led to the formation of the Committee of One Hundred on National Health, of which Professor Irving Fisher of Yale is president, and which includes among its members such men and women as Ex-President Eliot of Harvard, Dr. Lyman Abbott, Miss Jane Addams, Luther Burbank, Horace Fletcher, Professor Chittenden, Dr. Kellogg, and Dr. Trudeau.

The primary and immediate purpose of the Committee’s work is to promote the idea of a national Bureau of Health; but the field open to the committee includes the whole subject of public sanitation and hygiene. President Roosevelt has formally endorsed the work, in a letter from which the following is an extract: “Our national health is physically our greatest national asset. To prevent any possible deterioration of the American stock should be a national ambition. We cannot too strongly insist on the necessity of proper ideals for the family, for simple life and for those habits and tastes which produce vigor and make more capable of strenuous service to our country. The preservation of national vigor should be a matter of patriotism.... Federal activity in these matters has already developed greatly, until it now includes quarantine, meat inspection, pure food administration, and federal investigation of the conditions of child labor. It is my hope that these important activities may be still further developed.”

And in his notable message to the country, rather than to Congress, which he issued in December, 1907, President Roosevelt wrote: “There is a constantly growing interest in this country in the question of public health. At least, the public mind is awake to the fact that many diseases, notably tuberculosis, are national scourges. The work of the State and City Boards of Health should be supplemented by the constantly increasing interest on the part of the national government. The Congress has already provided a Bureau of Public Health, and has provided for an hygienic report. There are other valuable laws relating to the public health connected with the various departments. This whole branch of the government should be strengthened and aided in every way.”

As somebody said before, these things are no more true because a President has said them; but the fact that President Roosevelt has said them, has given wide publicity to them, and impressed them upon the public consciousness.

The knowledge that economic conditions;—the way in which men and women live because they have to so live in order to earn a living, is the fundamental factor in the case of public health, is something that is bound to become recognized as the growth of knowledge goes on. It will only be a question of time before men and women will see that in order to have health, it will be necessary to organize all the affairs of life with a view to the well-being of humanity as a whole.

In order to make effective the work of the Committee of One Hundred, its President, Irving Fisher, assisted by Professor Norton, organized the American Health League, which has absorbed the Public Health Defense League, an organization formed for the purpose of fighting the patent medicine evil, and awakening public interest in matters of hygiene. The Health League already numbers nine or ten thousand citizens, who are pledged to give financial and moral support to the work of the Committee of One Hundred in its efforts to establish a national Bureau of Health. The League is rapidly increasing in membership, for a spirit of interest in hygiene is abroad in the land. Local advisory committees have already been formed in more than two hundred cities and towns, and it is planned to prosecute the work of multiplying these branch committees until every town in the United States shall be represented in the membership. The Committee of One Hundred publishes the magazine _American Health_ as its official organ, and all American men and women who are interested in the spread of the new hygiene are invited by the Committee to correspond with its Executive Secretary, Drawer 30, New Haven, Conn.

Connected with the advisory and other subcommittees, are committees of writers, editors, and newspaper men, numbering many of our most prominent penmen and pressmen, and the power of molding public opinion through this channel alone is very great. There is now being organized a Council on Co-operation, to consist of the leading officers of American religions, fraternal, learned, secret, and educational organizations; and also a Council of Research, to consist of leading investigators interested in original research along public health lines.

In other words, the Committee of One Hundred has grown to a compact, well-organized, rapidly-spreading, national Army of Health. It has grown within a wonderfully short period, simply because there was a great and pressing _need_ for it.

Professor William H. Welch, a member of the Committee of One Hundred, and Professor of Pathology at Johns Hopkins University, has put himself on record as saying that if the nation were to apply in practice the existing knowledge of hygiene, the nation’s death rate would be cut in two. In commenting on this statement, Irving Fisher said:

“The greatest asset of all, the physical health of our citizens, is still neglected. Professor Nicholson, an economist of Scotland, has estimated that the living capital of Great Britain is worth five times the physical capital. That is, if we capitalize each man’s working capacity and add together this capitalization throughout the whole realm of Great Britain, the value of the population so obtained is five times the value of all the land and all the railroads and all the buildings, and all the iron mines and all the other capital which is ordinarily called wealth. If we could make this human capital within the United States double its present worth (it is already five times that of the inanimate capital), it is evident what an enormous improvement would ensue as compared with the possible improvements in saving arid lands, and other physical resources. Our health has much more than a money value. But these calculations show that even on the most materialistic method of reckoning, there is truth in Emerson’s statement, “the first wealth is health.”

FOODS AND THEIR ADULTERATION

WILEY

=BY THE SAME AUTHOR.=

=BEVERAGES AND THEIR ADULTERATION.=

OUTLINE OF CONTENTS.

I. Spring, well, and other potable waters.

II. Potable mineral waters.

III. Contamination of waters and how to avoid them.

IV. Coffee, Tea, Cocoa, Chocolate, etc.

V. Soda Waters, Pops, Seltzers, etc.

VI. Fermented Beverages--Growth of Raw Materials, Manufacture, and Storage: (_a_) Beers. (_b_) Wines. (_c_) Ciders, Perrys, Meads, etc.

VII. Distilled Liquors: (_a_) Whiskey. (_b_) Brandy. (_c_) Rum. (_d_) Gin and other flavored compounds. (_e_) Imitation and compound liquors. (_f_) Blends. (_g_) Cordials, denatured alcohol, etc.

VIII. So-called temperance drinks.

IX. Beverages of a miscellaneous character.

FOODS AND THEIR ADULTERATION

ORIGIN, MANUFACTURE, AND COMPOSITION OF FOOD PRODUCTS; DESCRIPTION OF COMMON ADULTERATIONS, FOOD STANDARDS, AND NATIONAL FOOD LAWS AND REGULATIONS

BY HARVEY W. WILEY, M.D., PH.D.

WITH ELEVEN COLORED PLATES AND EIGHTY-SIX OTHER ILLUSTRATIONS

PHILADELPHIA P. BLAKISTON'S SON & CO. 1012 WALNUT STREET 1907

PREFACE.

This manual is descriptive in character and aims to give, within its scope, as thoroughly and intelligibly as possible, an account of the various food-products in common use in their natural and manufactured conditions, with the usual adulterations which have been found therein.

It includes information regarding Methods of Preparation and Manufacture, Food Values, Standards of Purity, Regulations for Inspection, Simple Tests for Adulterations, Effects of Storage, and similar matters pertaining to the subject.

It has been designed to interest the consumer, as well as the manufacturer, the scientific, as well as the general reader, all of whom it is hoped will find in it something useful. The consumer is entitled to know the nature of the product offered, the manufacturer and dealer the best methods of preparation. It will give the physician and sanitarian knowledge of the value of foods, their proper use and inspection, and, while not analytical in purpose, will provide the chemist with information which will guide him in his work of detecting impurities.

It has been thought advisable to give in the appendices extracts from the national laws relating to the subject, as well as the rules and regulations for their enforcement and official standards of purity, as these are now of general interest to all classes. In revising the manuscript and in reading the proofs, especial recognition is made of the valuable aid of Dr. W. D. Bigelow, Chief of the Division of Foods of the Department of Agriculture; Dr. F. V. Coville, Botanist of the Department of Agriculture, and Dr. B. W. Evermann, of the Bureau of Fisheries. Acknowledgement is also made of the favors of the Bureaus of Plant Industry, Animal Industry, and Forestry. Many helpful suggestions from other sources can only be acknowledged in this general way. All opinions respecting adulterations, misbranding, nutritive value, and wholesomeness are the individual expressions of the author and are not to be considered in any other manner. Honest and truthful practices of manufacture and labeling are to be promoted in every possible manner. In the end the true, the ethical, and the just in these practices will prevail.

HARVEY W. WILEY.

WASHINGTON, D. C., _May 1, 1907_.

TABLE OF CONTENTS.

PAGE

INTRODUCTION 1-10

Proper Ration, 3; Social Function of Food, 5; Definition and Composition of Foods, 6; Classification of Foods, 7; Explanation of Chemical Terms, 8.

PART I.--MEATS AND MEAT PRODUCTS 11-94

Definition, 11; Edible Animals, 11; Classification of Meat Foods, 12; Preparation of Animals, 12; Inspection, 13; Tuberculosis, 13; Consumers' Rights, 14; Slaughter and Preparation of Carcasses, 14; Names of Parts, 15-20; Delivery of Fresh Meat, 21; Storage, 23; Disposition of Fragments, 23; Detection of Different Kinds of Meat, 24; Dried and Pickled Meat, 25; Composition of Pig's Flesh, 26-33; Preserved Meats, 34-38; Argument of Small Quantities, 38-40; Preparation for Canning, 41; Parboiling, 41; Sterilization, 42; Special Studies of Canning, 43-48; Relation of Canned to Fresh Beef, 48; Canned Ham and Bacon, 48-50; Canned Tongue, 50; Fat as a Test for Adulteration, 51; Potted Meats, 51-56; Canned Poultry, 56; Canned Horse-meat, 57; Canned Cured Meats, 59-60; Magnitude of Industry, 61; General Observations, 62; Lard, 63-77; Soups, 77-78; Beef Extract, 79-80; Beef Juice, 82; Soluble Meats, 83; Preparations of Blood, 83; Beef-tea, 84; Dried and Powdered Meats, 85; Active Principles in Meat Extracts, 86; Relation between Juice and Nutritive Value, 87; Nitrogenous Bases, 88-90; Gelatine, 90-92; Terrestrial Animal Oils, 93.

PART II.--POULTRY AND EGGS AND GAME BIRDS 95-116

Application of Name, 94; Domesticated Fowls, 95-116; Chicken, 95-104; Duck, 104; Goose, 105; Pigeon, 107; Turkey, 107; Forced Fattening, 109; Slaughtering and Preparing for Market, 111; Poisonous Principles in Eggs, 116; Parasites in Eggs, 116.

PART III.--FISH FOODS 117-166

Classification, 117; Edible Portion, 119; Principal Constituents, 119; Alewives, 121; Anchovy, 122; Black Bass, 122; Bluefish, 122; Carp, 123; Catfish, 123; Codfish, 124; Eels, 126; Flounder, 127; Graylings, 128; Haddock, 128; Hake, 128; Halibut, 128; Herring, 129; Horse Mackerel, 130; Hog-fish, 130; Mackerel, 131; Menhaden, 132; Mullet, 132; Muskallunge, 133; Pickerel or Pike, 133; Pompano, 134; Red Snapper, 134; Rock Bass, 135; Salmon, 135-138; Sardines, 139-140; Scup, 141; Shad, 141-142; Sheepshead, 143; Smelt, 144; Spanish Mackerel, 144; Sturgeon, 144; Caviar, 145; Striped Bass, 146; Sole, 146; Tautog, 147; Tilefish, 147; Trout, 147-148; Turbot, 149; Weakfish, 149; Whitefish, 150; Fluorids in Fish, 151; Marketing, 151; Cold Storage, 151; Canning, Drying, and Adulteration, 152; Value as Food, 153; Shellfish, 153; Clams, 153; Lobster, 155; Crabs, 155; Crawfish, 156; Shrimp, 157; Aquatic Reptiles, 157; Turtle, 157; Terrapin, 158; Mussel, 158; Oysters, 158-164; Animal Oils, 165; Marine Animal Oils, 165-166.

PART IV.--MILK AND MILK PRODUCTS AND OLEOMARGARINE 169-216

Milk, Limitation of Name, 169; Composition, 169; Method of Production, 169-174; Cream, 175; Curd Test for Purity, 176-178; Whey and Koumiss, 179; Buttermilk and Bonnyclabber, 181; Butter, 182-187; Oleomargarine, 187-189; Cheese, 190; Kinds, 191; Adulteration and Misbranding, 192; Coloring, 193; Cottage Cheese, 195; American Cheese Manufacture, 196-200; Grading Cheese, 200; Cream Cheese, 201; Foreign Types, 201-202; Sage Cheese, 203; English Cheese, 203-205; French Cheese, 206-208; Limburger, 208; Edam, 210; Bacterial Activity, 211; Chemical Changes in Ripening, 212-214; Digestibility, 214; Effect of Cold Storage, 215; Preparations of Casein, 215.

PART V.--CEREAL FOODS 217-273

Barley, 217-218; Buckwheat, 219-221; Indian Corn (Maize), 222-232; Oats, 232-236; Rice, 236; Rye, 237-239; Wheat, 239-242; Wheat Flour, 243-245; Gluten, 245-247; Bleaching, 247; Adulterations, 248; Standard Age and Substitutes, 248; Bread, 249; Yeast, 250; Ferments, 250; Chemical Aerating Agents, 251; Baking Powders, 251-254; Composition of Bread, 254-255; Comparative Nutritive Properties, 256-257; Biscuit, 258; Sugar Lost in Fermentation, 259; Texture of Loaves, 259; Macaroni, 260-264; Cakes, 265-267; Breakfast Foods, 267-271.

PART VI.--VEGETABLES, CONDIMENTS, FRUITS 273-388

Succulent Vegetables, 273; Artichoke, 274; Asparagus, 275; Bean, 275-276; Beets, 277; Brussels Sprouts, 278; Cabbage, 278; Carrot, 279; Cauliflower, 279; Celery, 280; Chicory, 280; Cranberry, 281; Cress, 281; Cucumbers, 281; Egg-plant, Garlic, and Gourds, 282; Horseradish, Jerusalem Artichoke, and Kale, 282; Leek, Lettuce, Melons, and Cantaloupe, 284-286; Okra and Onion, 286; Parsnip, 287; Peas, 287; Potatoes, 288-298; Potato Starch, 296-299; Rhubarb, 299; Squash, 299; Sweet Potato, 299-304; Turnip, 304; Yam, 304; Canned Vegetables, 305-315; Ketchup, 316; Use of Refuse in Ketchup, 317; Starches as Foods, 317-321; Condiments, 321-326; Fruits, 326-329; Apples, 330-335; Cherries, 336; Grapes, 337-338; Peaches, 339-341; Plums, 341; Quince, 342; Small Fruits, 342-343; Tropical and Subtropical Fruits, 343-348; Citrus Fruits, 348-369; Composition of Pineapple, 363-364; Ash of Tropical Fruits, 367; Sugar and Acid in Fruit, 369; Canned Fruits, 370-372; Fruit Sirups, 373-374; Jams, Jellies, and Preserves, 375-381; Manufacture of Jellies, 381-382; Compound Jams and Jellies, 383; Preserves, 384; Fruit Butter, 385; Brandied Fruit, 386; Importance of Preserving Industry, 386-388.

PART VII.--VEGETABLE OILS AND FATS, AND NUTS 389-428

Definition, 389; Chemical Characteristics, 390; Drying and Non-drying Oils, 391; Physical Characters, 392-393; Edible Vegetable Oils, 394-413; Cottonseed Oil, 397-401; Olive Oil, 402-405; Peanut Oil, 406; Rape Oil, 407; Sesame Oil, 408; Sunflower Oil, 409; Cacao-butter, 410; Coconut Oil, 411; Palm Oil, 412; Nuts, 413-428; Acorn, 414; Beechnuts, Brazil-nut, 415; Butternut, Chestnut, 416; Chinese Nut, 417; Coconut, Filbert, 418; Hazelnut, Hickory-nut, 419; Peanuts, 420-424; Pecan, 424-425; Pistachio, 426; Walnut, 426-428.

PART VIII.--FUNGI AS FOODS 429-454

Mushrooms, Production, 429-430; Varieties, 430; Food Value, 430; Distinction between Edible and Poisonous, 433-439; Types of Edible Mushrooms, 440; Horse Mushroom, 441; Shaggy Mushroom, 443; Fairy Ring Mushroom, 443; Puff-ball, 444; Cepe, 445; Fly Amanita, 446; Poisoning by Mushrooms, 448; Canned Mushrooms, 449; Truffles, 450-453; Food Value of Fungi, 454.

PART IX.--SUGAR, SIRUP, CONFECTIONERY, AND HONEY 455-494

Sugar, Origin of Sugar, 455; Beet Sugar, 456-465; Cane Sugar, 466; Maple Sugar, 467-468; Sugar Refining, 468-470; Sugar Production, 471; Adulteration of Sugar, 471; Sugar as Food, 472; Sirup, Maple, 472-473; Cane, 475; Sorghum, 476; Molasses, 477-478; Mixed Sirups, 479; Adulteration of Sirups, 480; Confectionery, 482; Materials, 482; Manufacture, 483; Crystallized Fruits and Flowers, 483; Food Value of Candy, 483; Adulteration of Confections, 483-486; Honey, Definition, Historical, 486; Preparation of Honey, 487; Beehives, 488; Distribution of Honey Industry, 489; Comb Honey, 489; Extracted Honey, 490; Properties of Honey, 491-492; Adulteration of Honey, 493-494.

MISCELLANEOUS 494-496

Mince Meat, 494; Pie Fillers, 496.

PART X.--INFANTS' AND INVALIDS' FOODS 497-500

Modified Milk, 497; Solid Infants' Food, 498; Invalids' Food, 498-499; Composition Infants' and Invalids' Foods, 500.

APPENDICES.

APPENDIX A 501-521

Food Standards, 501-517; Law Relating to Filled Cheese, 517-521.

APPENDIX B 522-537

Rules and Regulations for the Enforcement of the Food and Drugs Act, 522-533. The Food and Drugs Act of June 30, 1906, 533-537.

APPENDIX C 538-561

Regulations Governing the Meat Inspection of the United States Department of Agriculture, 538-556; Meat Inspection Law, 556-561.

APPENDIX D 562-615

Food Inspection Decisions under the Food and Drugs Act, 562-615. Food Inspections Decisions under the Imported Foods Act F. I. D.'s 1-39, 562-584. Food and Drugs Inspections and Decisions under the Food and Drugs Act F. I. D.'s 40-64, 584-615.

INDEX, 616-625

INTRODUCTION.

The growing importance to manufacturers, dealers, and consumers of a knowledge of food products has led to the preparation of the following manual.

Unfortunately, many misleading statements respecting the composition of foods, their nutritive value, and their relation to health and digestion have been published and received with more or less credence by the public. Claims of superior excellence, which are entirely baseless, are constantly made for certain food products in order to call the attention of the public more directly to their value and, unfortunately, at times to mislead the public with respect to their true worth.

It is not uncommon to see foods advertised as of exceptional quality, either as a whole or for certain purposes. Many of the preparations of this kind are of undoubted excellence, but fail to reach the superior standard or perform the particular function which is attributed to them. Particularly has it been noticed that foods are offered for specific purposes or the nourishment of certain parts of the body, especially of the brain and nerves. We are all familiar with the advertisements of foods to feed the brain, or feed the nerves, or feed the skin. It is hardly necessary to call attention to the absurdity of claims of this kind. One part of the body cannot be nourished if the other parts are neglected, and the true principle of nutrition requires a uniform and equal development and nourishment of all the tissues. It is true that many of the tissues have predominant constituents. For instance in the bones are found large quantities of phosphate of calcium and in the muscles nitrogenous tissues dominate. In the brain and nerves there are considerable quantities of organic phosphorus. All of these bodies, however, are contained in normal food properly balanced.

It would be contrary to the principles of physiology to attempt to feed the bones by consuming a large excess of phosphorus in the food or the muscles by confining the food to a purely nitrogenous component. Such attempts, instead of nourishing the tissues indicated, will so unbalance the rations as to disarrange the whole metabolic process, and thus injure and weaken the very tissues they are designed to support.

It seems, therefore, advisable to prepare a manual which may be used in conjunction with works on dietetics and on physiology and hygiene and yet of a character not especially designed for the expert.

The American public is now so well educated that any average citizen is fully capable of understanding scientific problems if presented to him in a non-technical garb.

It is, therefore, not difficult to see that the great army of manufacturers and dealers in food products, as well as the still greater army of consumers, are able to receive and to utilize information concerning food products which is of common interest to all. A

dissemination of knowledge of this kind will guide the manufacturer in his legitimate business and protect the public against deceptions such as those mentioned above.

In the evolution of society, economy and efficiency indicate that specializations should be made as completely as possible. For this reason it is advisable that foods of a certain character be manufactured and prepared for consumption on a large scale, so that due economy and purity may be secured. On the other hand there are many other kinds of foods which, by reason of their properties, cannot be prepared on a large scale but must be produced near or at the place of consumption. Milk is a type of this class of foods. It is altogether probable, therefore, that the consumption of manufactured foods will not decrease but increase even more rapidly than the number of our population.

In order that the people may be able to judge of the quality and character of products of this kind, information readily available appears to be highly desirable.

In the other case of the utilization of raw materials, it is equally important that the people of this country understand their nature and their functions in the digestive process. The great nutritive value of our food is found in the cereals, the meats, the fruits, and vegetables which we consume. A description of foods of this class, the places of their growth, the conditions under which they are matured and marketed, the problems which relate to their storage and transportation, their composition in respect of nutrition and digestibility, the dangers which may accrue from their decay, and the adulterations or sophistications to which they may be subjected are matters of the greatest public importance.

A treatise of this kind in order to be of its full value for which it is intended must be concise, expressed in simple language, in a form easily consulted, and yet be of a character which will be reliable and which will give full information on the subject.

It is a common habit of speech to divide foods into two great classes, namely, foods and beverages. This is not a scientific division, but is one which has been so well established by custom as to render it advisable to divide this work into two portions, one devoted to food in the sense just used and the other to beverages. The first volume of this work devoted to foods will treat of those bodies commonly known under the term “foods,”--namely, cereals, meats of all kinds, milk, vegetables, nuts, and fruits. The second volume will embrace the study of beverages, namely, natural and artificial mineral waters, soda waters, soft drinks, coffee, tea, cocoa, wines, cider, beer and other fermented beverages, distilled beverages of all kinds, and mixtures or compounds thereof.

In connection with the description of the origin of foods and their general characteristics will be given a statement of their chemical composition, especially in relation to nutritive properties. The principal adulterations or sophistications to which the food products are obnoxious will be briefly described, and where simple methods of detecting adulterations are known, of a character to be applied without special chemical knowledge or skill, they will be given.

An attempt is thus made to lay before those interested, in as compact a form as possible, the chief points connected with the production of food, its manipulation, and its use for the nourishment of the body.

It is not the intention of this manual to enter at all into the subject of cooking or the physiology of foods and nutrition. That is a distinct and separate part of this problem and has already been treated in many manuals. In this connection, however, attention may be called to the great importance of proper cooking in the use of food. Raw materials of the best character, prepared and transported in the most approved manner, may be so injured in the kitchen in the process of cooking as to be rendered both unpalatable and difficult of digestion. On the contrary, food materials of an inferior quality, provided they contain no injurious substances, may be so treated by the skilled cook as to be both palatable and nutritious. The desirability of the dissemination of correct principles of cooking is no less than that of giving information respecting the materials on which the art of cookery is exercised. It may be added that the art of cookery at the present time should not be confined to the mere technical manipulation, the application of heat and of condimental substances, but should also have some reference to the actual process of nutrition.

Foods should be prepared in the kitchen, not only of a palatable character and properly spiced but also selected in such a manner as to safeguard one of the chief purposes of food, namely, the proper nutrition of the body and the avoidance of any injury to digestion.

It is commonly admitted that many, perhaps most, of the diseases of the digestive tract to which the American people are so subject arise from the consumption of rations improperly balanced, poorly prepared, or used in great excess. To the intelligent and scientific cook the information contained in this manual will especially appeal.

A PROPER RATION.

The study of the science of nutrition has revealed the character of nourishment necessary to build the tissues and restore their waste. The term “food” in its broadest signification includes all those substances which when taken into the body build tissues, restore waste, furnish heat and energy, and provide appropriate condiments. The building of tissues is especially an important function during the early life of animals as it is through this building of tissues that growth takes place. The restoration of waste of tissues assumes special importance during that period of life when the weight of the body is supposed to be reasonably constant. At this time the waste of tissue in the natural processes is restored by the assimilation of new material in the same proportion.

If the assimilation of new material goes on at a greater rate than the waste of old material it manifests itself during the period of expected equilibrium in the deposition of adipose tissue and a consequent abnormal increase in weight.

In the after period of life the process of waste is naturally more vigorous than that of assimilation, and the tendency is manifested, which is wholly in harmony with the laws of Nature, to gradually diminish the weight of the body, and this continues to the extreme emaciation of old age.

It is evident, therefore, that the food consumed should be adapted to these changing periods. The growing animal needs a larger quantity of food in proportion to its actual weight than the animal which is in a state of equilibrium, that is, of mature age, and the animal which is entering upon the period of old age needs a less quantity of food in proportion to its weight than in either of the other periods of life. Thus, the rations of infants and children should be generous, the rations of mature man sufficient, and the rations of old age limited.

The food should also contain the various elements which enter into nutrition in the proper quantity. The nitrogenous constituents in food, when subjected to the ordinary process of digestion, yield a certain quantity of heat and energy but their more important function is to nourish the nitrogenous elements of the body, of which the muscles, hair, skin, and finger-nails are types. The mineral constituents of food, especially phosphorus and lime, have a general utility in promoting the metabolic functions, especially in the movement of the fluids of the body through the cell walls, and at the same time are actual nourishing materials, entering particularly into the composition of the bones and teeth.

The fats and oils which are present in the foods have the capacity of producing large quantities of heat and energy during their combustion in the body, and thus serve as a source of animal heat and muscular activity.

The starches and sugars which are the most abundant elements of our food, although they have a heat-forming power of less than one-half that of fats, are largely utilized in the production of heat and energy and in the formation of animal fat.

To secure a proper and complete nutrition of the body it is desirable that all these elements should be so adjusted as to provide for complete nourishment without having any one of them in great excess. It is evident that an excess of any one or more of these nutrient materials must necessarily impose on the organs of the body an additional work in securing their proper elimination. This tends to overburden the excretory organs and to cause a premature breakdown thereof. This giving away of the organs may not come for many years, not, perhaps, until advanced life, but when it comes it necessarily shortens the period of human existence.

The term =“balanced ration”= means the adjustment of nutrients in the food in such a way as to secure complete and perfect nutrition without loading the body with an excess of any one element. This is also an important point on the score of economy. A large percentage of all the earnings of man is expended for food products, and hence these products should be used in a manner to secure the best results possible. If, by a practice of scientific nutrition, 10 percent of the value of foods could be saved it would create a fund which, could it be utilized, would minister in the highest degree to the comfort and welfare of the human family and form an abundant pension for old age.

SOCIAL FUNCTIONS OF FOOD.

In the above paragraphs attention has been directed particularly to the nutritive and economic properties of food. It must not be considered that mere nutrition is the sole object of foods, especially for man. It is the first object to be conserved in the feeding of domesticated animals, but is only one of the objects to be kept in view in the feeding of man. Man is a social animal and, from the earliest period of his history, food has exercised a most important function in his social life. Hence in the study of food and of its uses a failure to consider this factor would be regrettable. For this reason it is justifiable in the feeding of man to expend upon the mere social features of the meal a sum which often is equal to or greater than that expended for the mere purpose of nutrition. This

part of the subject, however, belongs especially to the kitchen and dining room, and, therefore, will not be discussed at greater length at the present time.

It is believed that a more careful study of the food he consumes will benefit man in many ways. It will lead to a wider public interest in the problem of the purity of food and the magnitude of the crime committed against mankind in the debasement, adulteration, and sophistication of food articles.

This study will impart to the social function of food an additional charm, in that the origin and character of the material consumed will be known and the properties which they possess for nourishing the body understood. This will enable man, as a social animal, to so conduct himself at table as to secure the greatest possible pleasure and social benefit therefrom and at the same time avoid any injury which ignorance might permit and invite.

It may appear that the inartistic treatment of a subject of this kind, as indicated in the following pages, is not one which is calculated to excite any sympathetic interest or appeal to the natural desire for literary and artistic expression. Yet the importance of the subject is so great as to warrant the experiment of presenting the matter in this form rather than in any more elaborate and connected way.

DEFINITION AND COMPOSITION OF FOODS.

=Food=, in its general sense, is that which nourishes the body without regard to its physical state, that is, it may be solid, liquid, or gaseous. More particularly defined, food is that material taken into the body in the ordinary process of eating which contains the elements necessary for the growth of tissues, for the repair of the destruction to which the tissues are subjected during the ordinary vital processes and for furnishing heat and energy necessary to life. Incident to the utilization of these elements there is consumed, also, a considerable quantity of matter inextricably mingled with food in a natural way, which takes no direct part in nutrition and yet which is useful, as a mass, in promoting the digestive processes. These bodies are certain indigestible cellular tissues which are present in foods, mineral matter, and other materials which are naturally found in food products. Included in this broad definition, therefore, are many substances which are usually not thought of in the sense of food; among these are water and air. Air, however, would probably be excluded because it is not introduced into the stomach, that is, not in quantities which have any significance in the vital processes. Water, on the contrary, is one of the most indispensable constituents of food and is also used in considerable quantities as a beverage. The water, itself, is indispensable to nutrition and is also one of those bodies mentioned above which are necessary to secure the proper conduct of the digestive processes.

By means of the oxygen in the air the combustion of food in the various parts of the body is secured, and thus animal heat and energy developed. In this respect the combustion of a food product is similar in every way to the burning of coal in the production of heat and motion. The same calorific laws which govern the steam-engine are applicable, in all their rigidity, to the animal engine. The quantity of heat produced by the combustion of a certain amount of fat or sugar is definitely measured in a calorimeter and is found to correspond exactly to the quantity of heat produced by the ordinary combustion of such bodies. The term “food,” therefore, in this respect, would include the oxygen of the air without which the development of animal heat and energy would be impossible. It also includes those bodies of a liquid character which are classed as beverages rather than as foods. All of these bodies have nutritive properties, although their chief value is condimental and social.

That large class of food products, also, which is known as condiments is properly termed food, since they not only possess nutritive properties but through their condimental character promote digestion and by making the food more palatable secure to a higher degree the excellence of its social function.

It is now possible to condense into a distinct expression the definition of food in the following language: Food in a general sense embraces those substances taken into the body which build tissues, restore waste, and furnish heat and energy.

CLASSIFICATION OF FOODS.

Foods may be considered under different classifications. First, as to general appearance and use three classes may be made,--foods, beverages and condiments. As types of the first division of these foods may be mentioned cereals and their preparations, meat and its preparations (except meat extracts), fish, fowl, and game. Beverages are those liquid food products which are more valued for their taste and flavor than actual nutritive value. As types of beverages may be mentioned wines, beers, distilled spirits and liquors of all characters, tea, coffee, cocoa, chocolate, etc. Under wines, in this sense, may be included the

fermented beverages made of fruit juices, such as cider, perry, etc. Types of condiments are salt, pepper, spices, vinegar, etc. Milk, although a liquid substance, is hardly to be considered a beverage, and on account of its high nutritive properties may be classed, together with its preparations, under the first head.

Foods may also be classified as nitrogenous, starchy, oily, and condimental. Nitrogenous foods are those in which the proportion of their material containing nitrogen is large. Lean meat may be regarded as a type of nitrogenous food, since it consists almost exclusively of tissues known as protein and contains nitrogen and sulfur as essential ingredients. The white of an egg is also a typical nitrogenous food and, to a less extent, the yolk. Among vegetables, peas and beans are typical foods containing large percentages of nitrogenous matter. The gluten of wheat is also a typical nitrogenous food and the zein of Indian corn, corresponding to gluten, is a nitrogenous material.

Practically all the vegetables used as foods contain more or less protein in their constituents. Among the cereals oats has the largest quantity and rice the smallest of this valuable food material. Of oily foods the fat of animals, including butter, is a typical representative. All meats, fish, fowl, and game contain more or less fat. Of vegetables and fruits there are many which contain large quantities of fat, such as nuts, oily seeds, etc. All vegetables contain more or less fat, although the succulent vegetables usually contain but little thereof. Of starchy foods there are no types in animal food, the quantity of carbohydrate material therein being extremely limited. The lobster and horse-flesh contain perhaps a little more than 1 percent of carbohydrate food, but most meats contain much less than that. Sugar and starch are typical carbohydrate foods.

The cereal grains are composed largely of starchy foods, and so are certain tubers, such as the potato, cassava, etc. Of the common cereals rice contains more starch than any other and oats the least. Sugars are intimately related to starch and are included under the term starchy food or carbohydrate food. The carbohydrate matter in the flesh mentioned above, namely glycogen, is of the nature of a sugar. Among the typical sugar foods are beets, melons, and fruits, some of which contain large percentages of sugar. All fruits contain greater or less quantities of sugar, and that is true, also, of all vegetables.

Of the plants which produce the sugar of commerce there may be mentioned the sugar-cane, the sugar-beet, the maple, and palm trees. The principal sources of the sugar of commerce are the sugar-cane and the sugar-beet.

Of the condimental foods may be mentioned spices, including pepper, mustard, cinnamon, allspice, and other foods of this class. Common salt occupies a unique position in food products. It is the only mineral substance which has any value as a condiment in human food. But it also has a more important function than its condimental character, namely, it furnishes the supply of hydrochloric acid without which digestion in the stomach could not take place. For this reason common salt must be regarded as an essential food product as well as a condiment.

EXPLANATION OF CHEMICAL TERMS.

Inasmuch as this manual is not solely intended for expert chemists and physiologists but also for the general public, a simple explanation of the use of the terms used in analytical data and tables is advisable.

Under the term =moisture= is included all the water which is present in a free state, that is, not combined in any way with the ingredients of the material, and other substances volatile at the temperature of drying. The water is determined by drying to a constant weight at the temperature of boiling water or slightly above. In bodies which are easily oxidized this drying takes place in a vacuum or in an inert gas like hydrogen or carbon dioxid.

=Protein.=--Under this term is included all the nitrogenous compounds in a food product which contain in their composition sulfur, nitrogen, carbon, hydrogen, and oxygen, forming that class of tissues represented by the gluten in wheat, the white of an egg, muscular and tendinous fibers, etc.

=Ether Extract.=--Under this term is included the fats and oils, the term fat being applied to animal fat and the term oil to vegetable products. These bodies are all soluble in ether and therefore are grouped together under the term “ether extract.” There are some fats both in animal and vegetable substances insoluble in ether, but they exist in minute quantities and therefore are not separated from the extracts, but the whole matter is given together and represents practically the fats and oils in food.

There are also minute quantities of bodies not fats in foods soluble in ether, and these are included in the ether extract.

=Ash.=--The term ash is applied to the residue left after the burning of food products in the air at a low temperature until the carbon has disappeared. Ash is rather an indefinite term and is applied to that residual material of a mineral nature composed of sand or silica and the carbonates or oxids of alkaline earth or alkalies. The ash also contains the principal part of phosphorus present in food products and usually a small proportion of sulfur. These bodies in the ash exist as phosphoric and sulfuric acids or their salts.

=Fiber.=--The term fiber is applied to those carbohydrate products in food which are insoluble in solutions of dilute acid and dilute alkalies at the boiling temperature. Inasmuch as these separated bodies are not wholly pure cellulose they are often designated as crude fiber.

=Starch and Sugar.=--The terms starch and sugar are applied to the carbohydrates in a food product of a starchy or saccharine nature, together with the other carbohydrates present which are soluble in dilute acids and alkalies.

=Calories.=--The term calorie is used to denote the amount of heat-forming material contained in one unit weight of a food product. The number given represents the number of degrees of temperature produced in a unit mass of water by the heat formed in burning the unit weight of food. The unit weights employed are usually as follows: Of the food product, one gram (15 grains); unit weight of water to be heated, one kilogram (2.2 pounds); unit increment of temperature, 1°C. (1.8°F.). The expression 4000 calories therefore means that if one gram of food substance in a dry state be burned the heat produced will raise one gram of water through a temperature of 4000°C., or the unit of water (one kilogram) through a temperature of 4°C. For convenience the calories are usually expressed as small calories, namely 4000, instead of large calories, namely 4. In this manual the expression in terms of small calories, that is, the temperature increase of one kilogram of water produced by burning one gram of substance, multiplied by 1000, will be uniformly employed.

FOODS AND THEIR ADULTERATION.

PART I.

MEATS.

One great division of human food is meat. Technically, perhaps, the edible flesh of every animal used for human food might be described as meat. In this manual, however, preference is given to the common meaning of the term.

The flesh of animals is by common consent divided into three principal classes, namely, the flesh of terrestrial mammals, or animals not provided with wings; second, aerial animals, or animals provided with wings, and, third, aquatic animals. A very common classification of these three kinds of food is flesh, fowl, and fish. There are animals, the flesh of which is eaten by many, which are not exactly included in this classification; for instance, animals of an amphibious nature, living partly on land and partly on sea. Also many of the animals classed as aerial live chiefly upon the earth; although having wings they do not use them, such as domesticated fowls. This classification, however, is sufficiently exact for the practical purposes of a food manual and, therefore, under the head of meat is included the edible flesh of mammals living on the land.

=Animals Whose Flesh is Edible.=--Probably the only complete classification of this kind would be to include every animal living on the face of the earth since, perhaps, the flesh of every animal living has been more or less eaten by man. In a civilized community, however, except in times of disaster and dire necessity, certain classes of animals only furnish the principal meat food. Nearly all the meat food consumed in the United States is derived from cattle, sheep, and swine. Goat flesh is eaten only to a limited extent and horse meat scarcely at all, and the only other meats of importance are those of wild animals. The principal wild animals used for food are the deer, bear, rabbit, and squirrel. Many other wild animals, however, are eaten and in some cases highly prized. In this manual only the principal meat foods both of domesticated and wild animals will be mentioned.

=Classification of Meat Food as Respects Age.=--The edible flesh of domesticated animals as well as of wild animals is eaten both in the young and full-grown state. Common names, however, designate these different classes. For instance, veal in the growing and beef for the full-grown animal, lamb for the young and mutton for the full-grown sheep, pig in the younger and pork in the full-grown swine, etc. There is no legal limit of age for such a distinction, but as long as the animal is not fully grown it may be classified under the name representing the young animal. There is a common understanding, however, that in the case of veal and lamb the animal must be under one year of age and usually not under two nor more than eight months of age. A classification of this kind is so indefinite, however, that no strict definition can be given other than that founded on the general principles above

outlined.

=Preparation of Animals.=--The proper sanitary conditions attending the fattening of animals intended for slaughter are of great importance to the consumer. It is a common understanding that animals intended for slaughter should be plump and healthy. Poor animals, either those which are meager from lack of food or from disease, are to be rigidly excluded from the slaughter pen. Animals intended for slaughter should be fattened under sanitary conditions with plenty of fresh water and fresh air as well as good food. The stalls in which they are fattened should be clean and well ventilated, and the sanitary conditions surrounding them should be such as to exclude contagious and epidemic diseases and provide the most favorable environment for growth and preparation for the market.

It is evident that all these conditions are to be secured by proper inspection of the animals while preparing for the market. The time will, doubtless, soon arrive in this country when the supervision of the preparation of animals for the market, the sanitary conditions under which they live, and the general environment which surrounds them shall be subjects of local, municipal, and state inspection. Since the power of the general government cannot extend to states and municipalities, these corporate bodies should take uniform and scientific action concerning all these matters. National and state conventions of municipal and state sanitary authorities should decide upon uniform systems of inspection and sanitation to which all state and municipal authorities must agree, so that a uniform and effective method of inspection and sanitation will be secured throughout the country.

When animals are transported before slaughter from one state to another the national government is then entitled to inspect and certify respecting the condition of the animal thus to be transported from state to state. By thus combining municipal, state, and national inspection the rights of the consumer may be conserved, and this is the only means by which they can be kept inviolate.

It is assumed, therefore, that the animal which has been brought for slaughter has been fattened under proper sanitary conditions, has not been exposed to epidemic or contagious diseases, and outwardly is not afflicted with any disease of its own. Such a healthy animal may then be certified as fattened for slaughter.

=Inspection after Slaughter.=--The inspection after slaughter is of the utmost importance, not even second to that of the proper inspection during fattening and before slaughter. The veterinarian, skilled in his science, can tell by the inspection of the vital organs of the slaughtered animal whether it is affected with any organic disease. Among cattle the most frequent organic diseases are lumpy jaw and tuberculosis. In the case of swine one of the most common of diseases is trichinosis. In the latter case an inspection of the vital organs of the animal is not sufficient. The muscles of the swine, first and most commonly affected by trichinosis, must be examined microscopically in order to eliminate the possibility of the flesh of such animals going into commerce untagged or unnoticed.

If the flesh of the swine impregnated with trichinosis be thoroughly cooked practically all of the danger to man is eliminated. The consumer, however, should not be subjected to the chance of imperfect cooking. A swine affected with trichinosis should either be refused admission into consumption or should be so tagged that the consumer should know the danger to which he is exposed in order to take the necessary precaution to safeguard his health.

=Tuberculosis.=--There is a difference of opinion among veterinary and hygienic experts respecting the disposition which is to be made of carcasses affected with tuberculosis. It is claimed by some that if the tuberculosis is local, that is, does not extend beyond the lungs, there is no reason why the flesh of the animal should be refused to the consumer. The basis of this contention is founded upon the opinion of some of the most eminent veterinarians that bovine tuberculosis and human tuberculosis are entirely distinct diseases and cannot be transmitted either from the cow to man or vice versâ. It is not the province of this manual to decide this controversy, although it is only right that the consumer should be given the benefit of the doubt. Therefore, if the carcass of an animal affected with local tuberculosis is to be passed into consumption it should be plainly marked as the flesh of a tuberculosed animal,--not only the carcass as a whole, but every piece thereof that is introduced into consumption directly or after canning or mincing. The consumer is thus left free to choose for himself whether to eat such meat or not. There is a universal agreement among hygienists and veterinarians that where tuberculosis is generalized, that is, has affected practically all the organs of the body, the carcasses should be condemned. No one will take exceptions to this ruling, though it does not appear very plain to the ordinary consumer why a little tuberculosis is not a bad thing if a great deal of it is a very bad thing. There is an unfortunate tendency in many quarters to neglect minute effects and only pay attention to mass action. This does not seem to be a reasonable or desirable method of procedure.

=The Right of the Consumer.=--In all these cases of post mortem inspection it is the right of the consumer to be informed respecting the condition of the animal admitted to slaughter. Only the undoubtedly sound and healthy carcass should be given a free certificate. The badly diseased carcass should be condemned and refused admission to consumption. If the partially diseased carcass is to be consumed, it should be done under such a system of tagging as will absolutely protect any consumer against the use of the partially diseased carcass without his knowledge.

Summary.--The general conclusion reached is that the consumer has the right to protection in the character of food which comes upon his table. This protection begins at the time the animals are being fed for slaughter. It continues during the time the animals are slaughtered and afterwards in the preparation of their carcasses for consumption. It does not end until the meat is delivered to the consumer properly certified as being sound and wholesome and warranted to be free from deleterious coloring matter and preservatives. The consumers of this country can have this protection if they demand it. They outnumber the makers of meat products to such an overwhelming extent as to be able to secure proper legislation, because the manufacturers themselves, as consumers, are equally interested with others in this most important point, and should themselves receive for their families the same protection that the consumer who has nothing to do with the preparation of meat products is entitled to.

Since the above paragraph was written the Congress has provided for a complete inspection of meats as outlined therein.

=Slaughter and Preparation of Carcasses.=--It is not the purpose of this manual to enter into any discussion of the technique of slaughter and preparation of animals whose meat is intended to be eaten. It is believed that in this country the mechanism of this process is very near perfection, and especially so in the larger establishments where the highest skill is employed. In small slaughtering establishments and in farm slaughter there are found many points of technique which should be greatly improved. The principal thing to be considered is, first, a sudden and in so far as possible a painless death of the animal; second, the immediate withdrawal of the blood of the slaughtered animal if slaughtered otherwise than by opening the principal artery; third, the removal of the intestines and hair or hide of the animal; fourth, immediate cooling at a moderately low temperature until the animal heat is entirely radiated; fifth, the cutting of the carcass into the usual form for consumption and the removal and utilization of the débris for food or other purposes; sixth, the delivery of the meat, if to be eaten in a fresh state, in a condition secured from contamination and decay until it is in the hands of the consumer; seventh, the curing of the meat in a proper manner by salt, sugar, vinegar, and wood smoke, and the delivery thereof in an uncontaminated form to the consumer.

Natural Appearance of Cuts of Healthy Beef

Beef is the most important of any of the meat or flesh foods. To be able to judge of its freshness and freedom from disease is of great practical value. The following colored plates show the appearance of some of the principal cuts of beef in the proper condition for cooking. By comparing the appearance of the beef bought in all markets with these plates it is possible to form a sound judgment of their suitability for consumption.

These seven Plates are reproduced by courtesy of Armour & Co., Chicago

[Illustration: BEEF RIBS--REGULAR CUT]

[Illustration: BEEF RIBS--SPENCER CUT]

[Illustration: SIRLOIN BUTTS]

[Illustration: BEEF RIB]

[Illustration: BEEF LOIN]

It is not established that any further manipulation than that above outlined is desirable or necessary. The use of any kind of dye or coloring matter directly or indirectly, of any so-called preservative substance other than those of a condimental nature already mentioned, or any further manipulation save that to secure low temperature and freedom from infection is not useful, necessary, nor desirable. The sooner the manufacturer of these products understands the rights of the consumer in this respect and recognizes the fundamental verity of the above postulates the better it will be for all parties. When these conditions are met all of

the many and just objections which have been made to the meats of this country will pass away and they will assume in the markets of the world that position to which their natural merits, when not interfered with by maltreating during curing, entitle them.

=Names Applied to the Different Pieces of Edible Animals.=--In the preparation of animals for the market experience has shown that they are best cut in certain pieces of a shape determined by the race of the animal itself and to these pieces or cuts certain definite names have been applied. The method of making these cuts is not the same in all parts of this country and various parts of different countries. In the United States the most common cuts are illustrated in the accompanying figures, with the names which are attached thereto.

The analyses here reported apply to cuts as indicated by the following diagrams. These show the positions of the different cuts, both in the live animal and in the dressed carcass as found in the markets. The lines of division between the different cuts will vary slightly, according to the usage of the local market, even where the general method of cutting is as here indicated. The names of the same cuts likewise vary in different parts of the country.

[Illustration: FIG. 1.--CUTS OF BEEF.--(_Nutrition Bulletins, Office of Experiment Stations._)]

The Cuts of Beef.--The general method of cutting up a side of beef is illustrated in Fig. 1, which shows the relative position of the cuts in the animal and in a dressed side. The neck piece is frequently cut so as to include more of the chuck than is represented by the diagram. The shoulder clod is usually cut without bone, while the shoulder (not indicated in diagram) would include more or less of the shoulder blade and of the upper end of the fore shank. Shoulder steak is cut from the chuck. In many localities the plate is made to include all the parts of the fore quarter designated on the diagrams as brisket, cross ribs, plate, and navel, and different portions of the plate, as thus cut, are spoken of as the “brisket end of plate” and “navel end of plate.” This part of the animal is largely used for corning. The ribs are frequently divided into first, second, and third cuts, the latter lying nearest the chuck and being slightly less desirable than the former. The chuck is sometimes subdivided in a similar manner, the third cut of the chuck being nearest the neck. The names applied to different portions of the loin vary considerably in different localities. The part nearest the ribs is frequently called “small end of loin” or “short steak.” The other end of the loin is called “hip sirloin” or “sirloin.” Between the short and the sirloin is a portion quite generally called the “tenderloin,” for the reason that the real tenderloin, the very tender strip of meat lying inside the loin, is found most fully developed in this cut. Porterhouse steak is a term most frequently applied to either the short steak or the tenderloin. It is not uncommon to find the flank cut so as to include more of the loin than is indicated in the figures, in which case the upper portion is called “flank steak.” The larger part of the flank is, however, very frequently corned, as is also the case with the rump. In some markets the rump is cut so as to include a portion of the loin, which is then sold as “rump steak.” The portion of the round on the outside of the leg is regarded as more tender than that on the inside, and is frequently preferred to the latter. As the leg lies upon the butcher’s table this outside of the round is usually on the upper, or top, side, and is therefore called “top round.” Occasionally the plate is called the “rattle.”

In Fig. 2 is shown a side of beef with the various cuts indicated as used for commercial designation.

Tenderloins, Sirloin Butts and Strips cut from No. 4.

Rib Rolls cut from No. 5.

FIG. 2.--COMMERCIAL CUTS OF BEEF.--(_Courtesy of Armour & Co._)]

In Fig. 6 (page 20) is shown the interior view of a hog carcass with the cuts indicated as known to the trade.

[Illustration: FIG. 3.--DIAGRAM OF CUTS OF VEAL.--(_Nutrition Bulletins, Office of Experiment Stations._)]

The Cuts of Veal.--The method of cutting up a side of veal differs considerably from that employed with beef. This is illustrated by Fig. 3, which shows the relative position of the cuts in the animal and in a dressed side. The chuck is much smaller in proportion, and frequently no distinction is made between the chuck and the neck. The chuck is often cut so as to include a considerable of the portion here designated as shoulder, following more nearly the method adopted for subdividing beef. The shoulder of veal as here indicated includes, besides the portion corresponding to the shoulder in beef, the larger part of what is here classed as chuck in the adult animal. The under part of the fore quarter, corresponding to the plate in the beef, is often designated as breast in the veal.

The part of the veal corresponding to the rump of beef is here included with the loin, but is often cut to form part of the leg. In many localities the fore and hind shanks of veal are called the “knuckles.”

[Illustration: FIG. 4.--DIAGRAM OF CUTS OF LAMB AND MUTTON.--(_Nutrition Bulletins, Office of Experiment Stations._)]

The Cuts of Lamb and Mutton.--Fig. 4 shows the relative position of the cuts in a dressed side of mutton or lamb and in a live animal. The cuts in a side of lamb and mutton number but six, three in each quarter. The chuck includes the ribs as far as the end of the shoulder blades, beyond which comes the loin. The flank is made to include all the under side of the animal. Some butchers, however, make a larger number of cuts in the fore quarter, including a portion of the cuts marked “loin” and “chuck” in Fig. 4, to make a cut designated as “rib,” and a portion of the “flank” and “shoulder” to make a cut designated as “brisket.” The term “chops” is ordinarily used to designate portions of either the loin, ribs, chuck, or shoulder, which are either cut or “chopped” by the butcher into pieces suitable for frying or broiling. The chuck and ribs are sometimes called the “rack.”

[Illustration: FIG. 5.--DIAGRAM OF CUTS OF PORK.--(_Nutrition Bulletins, Office of Experiment Stations._)]

The Cuts of Pork.--The method of cutting up a side of pork differs considerably from that employed with other meats. A large portion of the carcass of a dressed pig consists of almost clear fat. This furnishes the cuts which are used for “salt pork” and bacon. Fig. 5 illustrates a common method of cutting up pork, showing the relative position of the cuts in the animal and in the dressed side. The cut designated as “back cut” is almost clear fat and is used for salting and pickling. The “middle cut” is the portion quite generally used for bacon and for “lean ends” salt pork. The belly is salted or pickled, or may be made into sausages.

[Illustration: FIG. 6.--COMMERCIAL CUTS OF PORK.--(_Courtesy of Armour & Co._)

1--Hind Foot 2--Ham 3--Rib Belly 4--Fat Back 5--Pork Loin 6--Cala Ham Butt 7--California Ham 8--Fore Foot 9--Neck]

Beneath the “back cut” are the ribs and loin, from which are obtained “spareribs,” “chops,” and roasting pieces, not designated in the figure. The hams and shoulders are more frequently cured, but are also sold fresh as pork “steak.” The tenderloin proper is a comparatively lean and very small strip of meat lying under the bones of the loin and usually weighing a fraction of a pound. Some fat is usually trimmed off from the hams and shoulders which is called “ham and shoulder fat” and is often used for sausages, etc. What is called “leaf lard,” at least in some localities, comes from the inside of the back. It is the kidney fat.

As stated above, cuts as shown in the diagrams herewith correspond to those of which analyses are reported in the table beyond, but do not attempt to show the different methods of cutting followed in markets in different parts of the United States.

=Delivery of Fresh Meat to Consumers.=--Perhaps the most important aid to the manufacturer, as well as a protection to the consumer, which modern science has offered to the public is the possibility of delivering fresh meats to consumers at a low temperature. A well equipped abattoir is provided with apparatus by means of which a constantly low temperature may be maintained in the room where the fresh meat is kept after the preparation described above. When the meats are to be distributed over long distances refrigerator cars or boats are provided where low temperature may be maintained.

=Roast Beef.=--The parts of the beef which are used for roasting are shown in the diagram, comprising a considerable portion of the hind quarter of the beef and part of the ribs. The roast is perhaps the most important of the parts of the beef for edible purposes. The average composition of the edible part of roast beef (before cooking) is given below:

Water, 60.14 percent Solids, 39.86 „ Nitrogen, 4.47 „ Phosphoric acid, .54 „ Sulfur, .26 „ Fat, 10.48 „ Ash, 1.30 „ Protein, 27.95 „

=Beefsteak.=--The most important parts of the beef next to the roast are the parts used for steak. Beefsteaks have different names, such as tenderloin and sirloin, and when the latter two are joined together by the bone the whole is called porterhouse. There are also round steaks and rump steaks which are less highly prized portions of the meat, but in nutritive value are probably quite as valuable as the others mentioned. The average composition of the edible part of a large number of samples of beefsteak is given in the following table:[1]

Water, 63.95 percent Solids, 36.05 „ Nitrogen, 4.54 „ Phosphoric acid, .59 „ Sulfur, .27 „ Fat, 5.93 „ Ash, 1.48 „ Protein, 28.37 „

[1] Means of numerous analyses in Bureau of Chemistry.

It is seen that the roast beef contains less water, less protein, and decidedly more fat than the steak.

=Roast Lamb.=--The parts of the lamb which are used for roasting are usually the hind quarters, although all of the parts are roasted at times. The average composition of a number of samples of lamb roast is given in the following table:[2]

Water, 58.56 percent Solids, 41.44 „ Nitrogen, 4.91 „ Phosphoric acid, .61 „ Sulfur, .28 „ Fat, 9.12 „ Ash, 1.30 „ Protein, 30.71 „

[2] From numerous analyses made in the Bureau of Chemistry.

=Lamb chops= or mutton chops are the short ribs with attached flesh of lamb or young sheep. They are considered to be the most desirable part of the young sheep or lamb for edible purposes. The average composition of the edible portion of a number of samples of lamb chops is given in the following table:

Water, 63.98 percent Solids, 36.02 „ Nitrogen, 4.35 „ Phosphoric acid, .61 „ Sulfur, .24 „ Fat, 7.09 „ Ash, 1.49 „ Protein, 27.18 „

Roast lamb, as shown by the above data, has less water, more fat, and more protein than lamb chops.

=Preservation of Fresh Meats.=--After delivery the meats are at once consigned to refrigerator departments in the markets, where they are preserved until they pass into the consumer’s hands. Thus, a properly fattened, properly slaughtered, and properly dressed piece of fresh meat may be brought into the consumer’s hands in a manner at once unobjectionable and at the same time one which secures it admirably from contamination of any kind. So perfect are these means of transportation that fresh meat may be sent not only from city to city but across the sea, and reach the consumer as near perfection as human ingenuity can devise.

=Length of Storage.=--The question of how long meat can be safely kept in cold storage of this kind is one which has not been decided. It may be said, however, that the period should not be extended any longer than is necessary and that the consumers of meat should be provided in ordinary times, if transportation is undisturbed, with practically fresh meat. It is evident that if the principal meat-packing centers are Chicago, Omaha, and Kansas City the cities and parts of the country remote from these localities must have meat somewhat older than those which are near by. If we pass to distant countries, as for instance, Europe, where fresh meats are received from the United States or even from Australia, the time elapsing between slaughter and consumption must necessarily be long. Thus the length of time in which meat should be left in cold storage after it is properly matured depends upon its geographic distribution and is not a matter to be decided arbitrarily.

When meats are not only kept in cold storage for transportation but are actually frozen, as is often the case, they can, of course, be kept for a much longer time than when subjected merely to a low temperature at or slightly above the freezing point. For this reason meats that are to be carried to a long distance and not to be consumed for a long time after preparation are usually frozen and kept so during transport.

=Effect of Low Temperature on Enzymic Action.=--Attention has been called to the fact that low temperature does not inhibit enzymic action, and, therefore, it must be admitted that this continued activity must gradually deteriorate the quality of the product. The question, therefore, which is the most important is not how long can meat be kept in a frozen condition but how short a time must it be kept. In all cases, therefore, of this kind the consumer is entitled to know the length of time during which his meat has been kept frozen, and this desirable condition of affairs is easily secured by the necessary local, state, and national inspection already mentioned.

=Disposition of Fragments Arising From the Dressing of Beef.=--It is evident that the fragments of sound, wholesome meat which is dressed for delivery to commerce are themselves edible and hence there can be no hygienic or other objection to preparations made from these fragments, such as sausage and other minced and comminuted meats which appear upon the market. In other words, the consumer is entitled to know that because a piece of meat is comminuted is no reason for supposing that it is not edible.

Sausage, mince meat, comminuted meat, potted, canned, and other meats or preparations from these sound, clean, edible fragments, necessarily rejected in the process of preparing fresh meats for curing and for consumption, are entitled to the same consideration and may be looked upon with the same certainty of purity by the consumer when properly inspected and prepared as the larger pieces.

The possibility of detecting any effects of disease in meats by inspection at the time of or after delivery is very remote and therefore the inspection before killing and during the process of manufacture should be a most rigid one in the case of these fragments. Such inspection and certification would restore public confidence in the purity and hygienic properties of these meats which not only are

nutritious but by the spicing and condimental treatment which they receive are rendered highly palatable and desirable.

DETECTION OF DIFFERENT KINDS OF MEAT.

When meats are in large pieces they may be recognized by their anatomical characteristics. In order that this may be done, however, the piece of meat must either be of a sufficient size to be recognized by its shape and general appearance or must have a bone of sufficient size to indicate its anatomical character.

According to the German law pieces of meat of less than eight pounds in weight are not supposed to be large enough to be recognized anatomically or otherwise with certainty. This, however, is a matter which pertains more to the meat of animals from which the bone is taken rather than to its actual size. It requires some little expert knowledge of the anatomy of animals in order to distinguish these pieces, but one who is in the habit of purchasing or cutting meats acquires this knowledge without any special study.

=Odor and Taste.=--Each kind of meat may also be detected both by its odor and taste, as well as by its physical appearance and shape. Beef, mutton, pork, and other meats in a proper state of preparation and preservation have characteristic odors and flavors by which they are easily detected. One of the common faults of cooking is the putting together of meats of various kinds in the same oven, by means of which the odors become so intermingled that in small pieces even the experienced taster may not always be able to discriminate between them.

=Detection of Meat by Microscopic Appearance.=--Meats are so nearly related histologically that the microscope is not a certain means of detecting the different varieties. Were this the case it would be easy to identify the different kinds of meat which may be found in a finely comminuted mixture. The expert microscopist may have difficulty in discriminating between different microscopic portions of meat, but the microscope is of practically no advantage to any but an expert and not a very great advantage to him. The fibers of some animals vary in size, coarseness or fineness of texture, and other characteristics as much as fibers do from different animals.

=Detection by Chemical Examination.=--The most satisfactory method of detecting meats is by means of their chemical examination. There are two distinct points which are kept in view in a chemical examination. One is the presence of glycogen, which in quantities of more than one percent is characteristic of horse meat. Unfortunately, this test can only be applied to a meat in practically a fresh state, as the glycogen is rapidly changed into other forms of carbohydrate substances which make it difficult to identify. The chemical examination, therefore, which is of the most value is that which is performed upon the fat. The fat of different animals has different physical and chemical characteristics. The fats crystallize in different forms and have different melting points,--also the fatty acids derived therefrom. They absorb different quantities of iodin and bromin, and have other physical and chemical properties which are peculiar to each variety.

A careful examination of the fat, therefore, will lead to an approximate degree of knowledge concerning the character of the flesh from which it has been derived. For instance, lard and beef fat are easily distinguished from each other. In case a minced meat is made wholly of one kind of flesh or of one kind of animal the chemical examination of the fat will, with a considerable degree of certainty, lead to its identification. In the same manner, if a minced meat be made up of equal parts of two different kinds of animals the characteristics of the fats will lead to the identification of the two sources of meat. If, however, one kind of meat be mixed in only a small proportion, say 10 or 15 percent, of another, the chemical methods of separation are not to be relied upon. None of these chemical or physical methods, unfortunately, is of value in the hands of any but an expert, and, therefore, cannot be regarded as a common means of identification. For this reason the only common manner of identification of the kinds of meats which are sent out to the consumer at large must consist in the general knowledge of their anatomical, physical, palatable, and gustatory properties outlined above.

In all cases the consumer must eventually rely upon the official inspection and the label which accompanies the meat or which should accompany it.

=Dried Meat.=--A very effective method of preserving meat is practiced in certain of the arid regions of the country by exposing it to the dry air and sunlight. Meats prepared in this way are often called “jerked” meats. The small amount of aqueous vapor in the air is not sufficient to maintain the life of the ordinary fermentative germs, and they are, therefore, destroyed by desiccation. Meat which is exposed under such circumstances does not become infected with any fermentative germ, and the moisture which it contains is

rapidly given off in the dry air surrounding it. For this purpose the meat is cut into thin strips and suspended by appropriate means in the air and exposed to the direct sunlight. In a short time the moisture disappears, and the hard dry pieces keep indefinitely in certain arid regions of this country. The meat also maintains a fair degree of palatability and practically all of its nutrient properties, so that when properly cooked it is a palatable and nutritious dish. Probably of all the methods of preserving meat this one is the least open to objection, since not even spices or condimental substances are necessary in order to preserve the meat from decay. By reason of the change in its physical appearance, however, which makes it less attractive, this method is not likely to come into general use in the ordinary preservation of meat.

Dried beef is also prepared by preserving the meat by condimental substances and, instead of placing it in brine, drying it artificially. Chipped or dried beef is a common article of commerce and is prepared in the manner described above. This meat, however, has already been treated with condimental substances, and hence the drying is only one of the means of preservation. Dried or chipped meats are often smoked also as well as desiccated, so that in their preparation more than one method of preservation is employed.

=Pickled Meats.=--The method of preserving meats in a liquid environment is sometimes called pickling. All kinds of meat are pickled in this way, but pork especially. The pickling brine may be simply made of common salt, though other substances, such as sugar, vinegar, and spices, are used. The brine also sometimes contains a chemical preservative which is highly objectionable on the general ground of the harmfulness of these substances. The preservative commonly used is either sulfite of soda or boric acid. The making of a pickled meat of this kind should be discouraged. The vinegar which is employed or acetic acid may be injected into the carcass before it is cut up. When the arteries or veins are filled with vinegar in this way it rapidly permeates to all parts of the meat and acts as an excellent and unobjectionable preservative in all cases where an acid taste is desired. It is claimed that carcasses which have been injected with vinegar in this way are easily preserved, and require far less salt and other condimental substances than when not so treated. As vinegar is a condimental substance used everywhere, and one which promotes digestion when used in proper quantities, the preservation of meats or the pickling of meats by a previous injection of vinegar is not objectionable.

COMPOSITION OF THE FLESH OF PIGS.

Extensive investigation of the composition of the flesh of pigs has been made in the Bureau of Chemistry (Bulletin 53). The pigs upon which these examinations were made were specially bred and fattened at the Agricultural Experiment Station of Iowa, and were prepared for the market by the most approved modern style of feeding. They were slaughtered according to the approved method and immediately, after proper preparation, the carcasses were placed in cold storage, where they were kept until removal for the purpose of dissection and preparation of the samples for analyses. Expert butchers from Washington were secured for the dissecting and dressing of the pigs in the manner in which it would be done for the best market. The pigs were of different varieties, namely, Berkshire, No. 1; Tamworth, No. 2; Chester White, No. 3; Poland China, No. 4; Duroc Jersey, No. 5, No. 6, No. 7; Yorkshire, No. 8.

[4] Corrected for missing hoof.

=Preparation of Samples for Analyses.=--The meat obtained from all of the cuts of the same kind in each sample was passed through a meat chopper two or three times in order to get an even, finely divided condition. A portion of known weight was then placed in a dish and dried in a steam oven at a temperature of boiling water or slightly above and heated until the fat had well separated so that it could be poured off into a flask, with care not to remove any of the water which may have separated with it. Small samples were removed before drying for the determination of the exact quantity of fat and water therein, and the results of these analyses were used for calculating the relative portion of the large samples. Samples of skin, bones, marrow, spinal cord, tendons, hoofs, and other parts of the animal were also carefully secured and subjected to analyses. In this way the whole animal was subjected to examination for analytical data, and at the same time each particular part of it, in so far as its relation to the market is concerned, was kept separated. In Table A are found the weight of the whole cut and the data relative to the preparation of the air-dried sample.

The data show that there was a slight loss of water during the transit from Chicago to Washington. The part of the pig which has the largest percentage of fat is the meat of the tail, while the smallest percentage is found in the tenderloins. The largest percentage of water in any part of the meat is in the tenderloins and the smallest in the meat of the tail.

[5] In this column the totals obtained by both the direct and the indirect determination of water and fat are given. The upper number in each case was obtained by use of the results of direct determinations of these constituents; for the lower number in each case the results obtained during the preparation of the sample, and in the analysis of the dry-air sample, were used. Lecithin is not included in the totals given in this table.

Similar data were obtained for all of the other samples used, but the chemical composition is so nearly the same that it is not advisable to repeat the data for the other varieties. The Berkshire for which the data are given may be taken as a fair representative of the composition of the varied parts of the meat of pigs. The comparative weights of various parts of the Berkshire pig are given in Table B.

The data show that 88.19 percent of the weight of the carcass, after dressing, is composed of meat, fat, and lean, and 7.56 percent of bone. The complete data for the variety of Berkshire pig may be taken as a type for the other varieties and is given in Table C.

The composition of the bone, marrow, skin, spinal cord, tendons, and hoofs of the Berkshire pig is shown in Table D.

The percentages of the various parts of the original material of the Berkshire pig are found in Table E.

[11] In fat extract.

[12] In residue and fat extract, calculated from averages of like cuts.

[13] Calculated from average of like cuts.

The data for the entire dressed animal after the removal of the head, hoofs, lard, and kidneys are shown in Table F.

=General Conclusions.=--The composition of the flesh of pigs has been given in detail for two reasons. First, because the data relative to this point are much more complete than those of any other flesh product and were obtained in a more systematic way. In the second place, pork is one of the chief meat products of the United States,--the industry being one of great magnitude, and pork being a common article of diet among all classes of people. Further than this, the data indicate the general character of fresh meat, and illustrate as well as that of any of the typical animals the nutritive value and properties of flesh. The study of pork, therefore, may be regarded as a typical study of meat products. It is quite as important that all people should be informed respecting the nature of the wholesome meat which they consume and its value as a diet as it is that they should be certain these meats be procured from healthy animals and in a sanitary way. These two classes of knowledge together give a complete scheme of information which the consumers in this and other countries are entitled to have.

Pork, by many hygienists, is regarded as the least desirable of meat products, and it is not the purpose here to combat that idea. Granting, however, for the sake of argument, that pork is a less desirable meat food than those derived from cattle or sheep, that is all the more reason for knowing particularly everything connected with it. Modern investigations have appeared to establish the fact that swine are less subject to those forms of disease, with the exception of trichinosis, which tend to infect the meat and make it unfit for consumption than cattle or sheep. The diseases to which swine are usually subject act quickly, as a rule, and are speedily fatal, as in the case of hog cholera, whereas the diseases most to be feared in cattle and sheep are those of slow activity and those of a nature which is often not revealed until slaughter, namely, tubercular diseases. In so far, therefore, as infection from disease is concerned, previous to slaughter, it appears that the flesh of swine is less objectionable and less open to suspicion than that of cattle or sheep. One of the chief objections to the use of pork in any form, whether fresh or cured, has been based upon the unsanitary habits of the animals themselves. With the modern methods of cleanliness and care, however, the conditions under which the pigs grow and fatten are, or should be, quite as sanitary as those surrounding cattle and sheep. The consumer, of course, has the right to insist upon such sanitary conditions and these, under present laws or those which are to be enacted, will doubtless be supplied. It is believed that in this country sanitary environments and a sanitary method of feeding will develop types of animals superior to those grown in other countries, where the population is denser and where the facilities for the proper growth and fattening of the animal are less abundant. It is hoped that the general diffusion of knowledge respecting all food products among our people will aid greatly in securing these very desirable results.

PRESERVED MEATS.

Meats which cannot be eaten at the time of or soon after slaughter are necessarily preserved until the time of consumption. It is difficult to draw a definite line between a preserved and a fresh meat. A general distinction is the following: Fresh meat is meat which is prepared for consumption without the use of any condiment or preservative, without sterilization, and with none of the artificial methods of keeping, except cleanliness and a low temperature.

The above definition, as will be seen, covers meat placed in cold storage. A special distinction, however, must be made in this case between meat placed in cold storage for the purpose of transportation only and meat placed in cold storage to be kept for an indefinite time. Where meats are prepared for consumption by slaughter and appropriate dressing and shipped long distances to the consumer the cold storage car, ship, and warehouse become a necessity. There is some reasonable limit for keeping such products, beyond which they should be differentiated from fresh meats. Whenever meats are kept in cold storage so long as to afford the opportunity for the growth of a mould, or undergo other changes of a chemical or physical character which distinguish them from the fresh products, they should be placed in a different class. Fresh meats may, therefore, be divided as follows:

Class I. Meats intended for immediate consumption and passed to the consumer within, at the most, one week after slaughter. Class II. Cold storage meats, which are placed in refrigerators, frozen, and kept for a longer period than one week. There is evidently also a limit to the length of time which meat should remain in cold storage, no matter how low the temperature may be, since the action of organisms which produce decay cannot be entirely overcome. The exact limit at which frozen meats can be kept without becoming inedible has not been determined. Without this determination, however, it is advisable that such limit should not be approached. Inasmuch as the supply of fresh meat is practically uniform, or can be made so by the dealer therein, there seems no good reason for the storage of meat in refrigerator compartments for a longer time than is necessary for transportation and a reasonable time thereafter for passing into consumption, except in cases of emergency. It might be safe to say that no meat should be kept in a cold storage warehouse longer than a month after its reception. Numerous instances might be cited in which meat may be kept for a much longer time, but the question for the consumer is not how long a while meats can be kept but how soon they can be placed in his hands. In this connection it should not be forgotten that it is the opinion of perhaps the majority of hygienists and connoisseurs that fresh meat, especially beef, improves for a certain length of time in cold storage. It is probable that the fresh beef which is served to the people of the United States is on an average a month old, and is said to be improved by keeping this length of time. This is a question, however, which is still undetermined, and it deserves a further investigation. Under present conditions it is well to know the truth respecting these matters and to realize that the fresh meat we get, such as beef and mutton, is not direct from the shambles but has been kept for at least four weeks in cold storage.

=Effect of Long Cold Storage.=--It has been stated in semi-scientific publications that the flesh of a mammoth incrusted in polar ice and presumably thousands of years old has been found to be intact and edible. This story, lacking corroboration, is hardly in harmony with known facts. The author had the opportunity of examining a quarter of beef which had been kept frozen in a warehouse for more than eleven years. This meat was found to be wholly inedible. It had an unpleasant and mummy-like odor, was light in fiber and color, having evidently lost a large part of its weight, and was of a character wholly unsuitable for consumption. This fact appears to show that eleven years is too long a time in which to keep meat frozen. In fact, it is scarcely worth while, from a practical point of view, to discuss so long a limit. Only the necessary time for the preparation and transportation of the meat is to be considered, and the sanitary laws of the nation, states, and municipalities should undoubtedly regulate the time of cold storage and see that all packages of meat exposed for sale are plainly tagged as to the date of slaughter, in order that the consumer may know.

In the consideration of the subject of preserved meats there are excluded all meats delivered in the fresh state for consumption and meats kept in cold storage in a fresh state during the necessary time of preparation and transportation say, on the whole, from four to eight weeks. Meats kept longer than this may generally be considered as preserved meats, even when cold is the only factor active in their preservation.

=Method of Preserving Meats.=--Aside from cold storage there are four methods in vogue for preserving meats. These may be classified as follows: (1) Curing with the aid of condimental substances; (2) treatment with chemical and non-condimental preservatives; (3) sterilization with heat; (4) drying. These all except the second may be regarded as legitimate means of preserving meats.

=Curing with Condimental Substances.=--This method of preserving meat has been practiced from the remotest antiquity. The chief condimental substances employed are salt, sugar, vinegar, and wood smoke. With the proper technical skill and knowledge of the

process, meats can be preserved in this way, and at the same time aromas and flavors developed which are considered most agreeable by the consumer and which give an additional value to the product. It is not to be claimed in any case that condimental preservatives add anything to the nutritive value of the product, except in so far as condiments themselves aid the digestion by exciting in a perfectly proper way the activity of the glands which secrete the digestive ferments.

It is not the purpose here to describe the technical processes used. In general it may be said that the application of salt is the first process, and this is done as soon after the slaughter as possible to secure the proper cooling of the carcass, usually from twenty-four to forty-eight hours. The meat, properly cut into the forms known to commerce, is carefully packed and heavily salted, and allowed to remain for some time in contact with the salt or with the brine which is produced therefrom. The salt penetrates to the interior of the flesh and hardens, to some extent, the tissues, abstracting water therefrom, and, without being wholly germicidal in character, prevents the introduction of eggs of insects and the development of ordinary germ life. The salt, however, does not entirely inhibit the enzymic action which tends to ripen the meat and make it more palatable. It naturally gives to the meat the salty flavor which is demanded by the taste in a preparation of this kind.

Sugar is used, if at all, always in connection with salt as a preservative for meats. It may be employed in the pure state, but is usually the yellow or low-grade sugar or molasses. It gives to the preserved meat, especially ham, a flavor and quality much appreciated by the consumer.

The application of wood smoke is usually the last process after the meats are properly cured in salt and sugar. The pieces are suspended in a convenient room and underneath is built a fire of hard wood, which is kept smouldering as much as possible in order to produce the maximum of smoke and minimum of heat. Oak, maple, and hickory woods are most highly prized for this purpose, since they develop on burning a rich aroma which imparts to the flesh a delicate flavor.

The object of curing the meat is, first, to prevent decay; second, to impart the flavor of the well known condiments mentioned above, and third, to favor the development of the enzymic action which has the property not only to make the meat more aromatic than it otherwise would be, but also more pleasant to the taste.

The curing of meat in this respect may be compared to the development of a cheese, except that the enzymic action in the case of meat is one of minimum extent, while in the case of cheese it is one of maximum intensity. In addition to the condimental substances above mentioned spices of different kinds are sometimes added. Vinegar is also used at times as a condimental substance and is, to a certain extent, also a preservative substance, but vinegar is chiefly used in the preservation of vegetable substances rather than meats in bulk. For meats which are spiced as well as preserved as above, vinegar is often used as one of the ingredients, intended as a condimental substance. No other substances than those mentioned above are necessary to the proper curing of meat, but convenience of application and certain other considerations have led packers of meats, when not prevented by law, to abandon the old methods to a certain extent and substitute what is known as the quick-aging process described below.

=Preservation by Means of Non-condimental Chemical Preservatives.=--The use of non-condimental chemicals in the preservation of meat is practically an industry of the last quarter of a century. Up to that time the use of non-condimental chemicals was practically unknown in the meat industry. The chemicals employed are those known as germicides. In the quantities used they neither impart a taste nor odor to a preserved meat, but by their germicidal properties prevent the development of organic ferments and thus make the preservation of meat far more certain and very much less expensive. By the use of some chemicals the salting, sugaring, and smoking of preserved meats may be done with very much less care, in a very much shorter time, and at a very greatly reduced expense. For this reason the practice has gained a great vogue, not as a means of benefiting the consumers, but rather as a means of enriching the packer and dealer. Chemical preservatives are also highly objectionable because they keep meats apparently fresh, while in reality changes of the most dangerous character may be going on. They thus prevent the display of the red light danger signal.

=Preservatives Used.=--The principal chemical preservatives used in the curing of meats are borax and boric acid and sulfite of soda. There are many other chemical preservatives which have been employed, but these are by far the most useful, the most certain, and the most widely employed. Borax and boric acid, of the two classes, are by far the more common. Sulfite of soda is used more as a preservative of color, and is probably found more frequently on fresh than on preserved meats. Borax has the property of paralyzing fermentative action and thus securing immunity from decay. Its use, however, tends to diminish the palatability of the meat because of its restraining influence upon the condimental method of preservation described above. The

meats are more quickly preserved, require less condimental substances, and the borax probably inhibits, to a certain degree, the enzymic action of a favorable kind, described above.

The use of any kind of a chemical preserving agent on meat is most reprehensible, no matter what they may be. Unfortunately, experts differ respecting the influence of these chemical preservatives upon health. The users of chemical preservatives have employed experts of known fame and distinction to testify in favor of these products, while the consumer, perhaps, is not able to go to the expense of securing expert testimony, and, therefore, as respects numbers of witnesses, at least, chemical preservatives have an advantage. In a case of this kind the accused must be considered guilty until proven innocent. It is not sufficient to prove in a given case that borax is not injurious. If it be proven that it is injurious in a single case conviction must ensue. There is no doubt of the fact that the injurious character of borax, even in small quantities, has been fully established, and therefore any amount of testimony to the effect that in individual cases it has not produced injurious results is of no value whatever. If a citizen be robbed and in the course of the prosecution it be shown that there are a million citizens who have not been robbed by this criminal the evidence would be of no value. If it has been shown that the individual citizen has been robbed the prisoner is convicted. No expert would testify that borax has never been injurious,--even those who appear in its favor admit that, but plead that it is generally used in small quantities, and, therefore, cannot be harmful.

=The Argument of Small Quantities.=--The fallacy of the argument for small quantities is so evident that it needs only to be presented in brief form to show the intelligent and thinking people of this country the fallacy of the claims of experts in favor of chemical preservatives.

The arguments which have been advanced in excuse of the use of preservatives when used in minute quantities have, perhaps, been more vigorously urged for salicylic acid than for almost any other substance. This argument has been urged with such vigor and such ingenuity that a further reference may not be out of place here. The principle which is laid down is that a substance which is injurious to health when added to foods, if not a natural constituent thereof, or if not added for condimental purposes, does not lose its power of injury to health because it is diluted or given in small quantities. The only change which is made is to mask the injurious effects produced--to make them more difficult of ascertainment and impossible of measurement. The fallacy of the argument that small quantities of an injurious substance are not injurious may, perhaps, be best represented graphically. The accompanying chart (Fig. 7) shows theoretically the normal and lethal dose of a food and a drug or, as in this case, a chemical preservative. The chart shows two curves, one representing a chemical preservative and one representing a food. The normal dose of a food is that quantity of food which maintains a healthy adult body in equilibrium. It is represented in the chart on the right by the number 100. If the quantity of food necessary to maintain the equilibrium in a healthy adult body is slightly diminished, no apparent change is at first experienced and possibly even no discomfort. If, however, the quantity of food be still further diminished progressively, as indicated by following the curve down to the left, the point is finally reached when no food is given at all and death ensues, represented by 0 on the left hand of the diagram designated “Lethal dose.” As the curve begins to deviate from the perpendicular on the right the degree of injury is very readily noticed and starvation or symptoms of starvation are set up. Thus if you follow the perpendicular on the right downward to the point 80 the divergence of the corresponding point of the curve is already measurable. As you descend to 0 the magnitude of the measurement increases. It requires but very little further illustration to show how easily the effect of diminishing the normal dose of a food can be measured immediately after the curve begins to vary appreciably from the perpendicular on the right.

[Illustration: FIG. 7.--GRAPHIC CHART REPRESENTING THE COMPARATIVE INFLUENCES OF FOODS AND PRESERVATIVES.]

Let us now consider the perpendicular on the left, which is marked at the top under the term “Lethal dose,” namely, a quantity of the added preservative sufficient to destroy life. The normal dose of such an added chemical preservative is 0 and is shown at the base line to the right, marked “Normal dose.” If you add a very minute quantity of a chemical preservative, the curve representing it varies so slightly from the horizontal base as to be impossible of measurement by ordinary means. If we follow along to the number 75 on the horizontal base we see the deviation of the curve is sufficiently great to measure. At 50 it is still greater, at 25 still greater, while at the left of the basic line it is a maximum extending from 0 to 100, or the lethal dose. It is easy to show by mathematical data that no matter how small the quantity of an injurious substance or preservative it will still produce an injurious effect which may be infinitely small if the dose be infinitely small. It follows, then, as a mathematical demonstration that any quantity of an injurious substance added to a food product must of necessity be injurious, provided it is in the nature of a drug and the body is in a perfectly healthy, normal condition.

Hence the argument which has been so persistently urged in favor of a chemical preservative, that if in small quantities it is harmless, is shown to be wholly untenable. While there is no necessity for the addition of a harmful substance, where no particular benefit is secured thereby, and where there is no disturbance of the normal state of health, there can be no possible excuse of a valid nature to offer for the exhibition of even minute quantities. That these minute quantities would not be dangerous in so far as producing any fatal effect is concerned is conceded, but that in the end they do not produce an injury even in these small quantities is certainly to be denied. The course of safety, therefore, in all these cases is to guard the opening of the door. If the admission of small quantities is permitted, then there can never be any agreement among experts or others respecting the magnitude of the small quantity, and continued litigation and disagreement must follow. On the other hand, when the harmfulness of any substance which it is proposed to add to food is established and no reason for its use can be given other than the convenience, carelessness, or indifference of the manufacturer, the exclusion of such bodies entirely from food products follows as a logical sequence and a hygienic necessity.

The third method of preparing or preserving meat is by sterilization. Of all the various methods which have been proposed there is probably none which is, theoretically, so free of objections as the preservation of meat by sterilization, in other words, as canned meats. The only important thing is that the raw material used in canning must itself be meat free of disease, obtained under sanitary conditions, and subjected to sterilization before any fermentation or decay takes place. Pure, wholesome meat thus prepared and thoroughly sterilized will remain in an edible condition for a reasonable length of time. Unfortunately, as has been shown in the testimony respecting the packing industry of the country, canned meats have not always been selected solely for freedom from disease and for palatability. The question of diseased meat is discussed in another part of this book and, therefore, may not be taken up here. There have been used for canning purposes the fragments and, perhaps, inedible portions of carcasses, and this practice cannot be too severely condemned. This does not mean that these fragments and portions of carcasses are not fit for food, but they should be collected, prepared, and sold as such with plain notices to the consumers of their origin. A cheaper supply of beef would thus be furnished for those in humbler circumstances, and no imposition of any kind would be practiced because the nature of the meat would be fully understood.

=Preparation of Meat for Canning.=--In the following description it is understood that the ordinary processes of canning sound, properly prepared beef are described. The question of the canning of improper samples is reserved for the remarks on adulterations.

There is no uniform practice followed, as has been carefully ascertained by a study of the different packing houses and processes for selecting and preparing meats for canning. The exigencies of trade determine this to a greater or less extent. When there is a demand in the fresh state for all the beef which can be supplied the canning industry will necessarily suffer. When there is a surplus of beef offered for sale or in case of war, where the army contracts for large quantities of canned meat, the opposite conditions probably prevail, and the best meats are used for canning purposes and those of a less desirable quality offered for sale in the fresh state. The portions of the carcass used, as described in Bulletin 13, Part 10, Bureau of Chemistry, depend, to some extent, upon the market of fresh beef. All of the meat on the fore quarter, except the shank and the “third rib,” is usually canned, and in some cases those portions are not reserved. The cheaper cuts from the hind quarter are also used for preserving purposes. Very fat, and therefore easily marketed, carcasses are not used for canning purposes except in case of unusual demand as above stated. There are two reasons for this, one of which has already been outlined, namely, that such meat brings a better price in the fresh state, and, in the second place, lean meat has a better appearance in the canned state than the fat meat. For these reasons, in the proper preparation of the meat for canning, the more fatty portions, together with the gristle, are removed and sent to other parts of the factory for making up into other kinds of food.

The meat having been selected, it is cut into pieces of approximately from one to four pounds in weight, according to the size of the tins in which it is to be placed. It is important, for the purpose of appearances, that the size of the pieces of meat in each tin be approximately the same. Also for the process of sterilization the pieces of meat should be practically the same size, so that they can all be thoroughly sterilized at the same time. If the pieces be of different sizes the small ones would become thoroughly cooked and disintegrated before the large ones became thoroughly sterilized, and thus the mass which would be presented to the view on opening the can would be unpleasant to the sight.

=Parboiling.=--After the pieces have been selected and dressed they are parboiled before being sterilized. The time of parboiling varies in different packing establishments from eight to twenty minutes, according to the size of the pieces of meat. In some cases a uniform time for parboiling is prescribed, irrespective of the size of the pieces. One of the principal reasons for parboiling the meat

is to secure the shrinkage, which always takes place on heating, before the meat is placed in the tins.

The experiments have shown that meats when put in tins in a fresh state and sterilized shrink to about two-thirds of their original volume. Parboiling is, in the essence, a process of shrinking. When the meat is put at once into boiling water there is less loss of protein matter than when the meat is placed in cold water and heated gradually. The substances removed in parboiling are water, fat, soluble mineral matter, and the meat bases. The fat is removed by becoming rendered, and rises to the surface where it can be skimmed off. A little over one percent of the protein content of meat is lost by parboiling while the total meat bases lost amount to almost one-third of the total quantity contained in the meat. Of mineral matter in the meat as high as 50 percent is lost in parboiling.

By shrinking, parboiling tends to make a more concentrated article and thus favors transportation. Practically the nutritive value of a pound of properly canned beef is about one-third greater than that of one pound of the fresh beef of the same kind. Hence parboiling may be regarded as a perfectly legitimate and desirable process without which the beef could not be properly prepared for canning.

=Tinning.=--After the meat is properly parboiled it is placed in the tins either by machinery or by hand. To each tin is added a small quantity of a liquid preparation made by the canners and known as soup liquor. This liquor generally contains salt, and sometimes a little sugar or molasses. The composition of soup liquor is as follows:

Solids, .92 percent Protein, .09 „ Meat bases, .23 „ Ash, .28 „ Salt, .11 „ Water, 98.37 „

This soup liquor may be regarded as a thin soup. The origin of the liquid analyzed above was not disclosed, and, therefore, no expression can be made of the way in which it was formed. It was probably made from soup stock, namely, the waste meat and bones of the factory. There is no objection to a soup liquor of this kind provided it is made from sound, clean, and wholesome material. There are two reasons for adding this liquid, namely, to fill up the space which would otherwise exist between the pieces of meat and thus aid in the preservation of the material, and, second, to add a condimental substance which makes the contents of the tin more palatable.

=Sterilization.=--After the cans are filled in this way and closed by soldering or otherwise they are placed in retorts which are composed of strong iron or steel boilers, properly covered and secured, and when these boilers are full they are subjected to the action of steam heat under pressure. Usually a small hole is left in the can through which any gas, air or other kind, is expelled from the can. As soon as everything is complete the retorts are opened and the cans are sealed.

In all cases, however, after sealing the cans they are subjected to a second heating at a temperature of from 225 to 250 degrees F. The time of heating varies from one to two hours. After removal from the retorts the cans are washed with a spray of cold water for several hours, and they are then dried, painted, and labeled.

The above is a general description of the process employed which, however, is varied to some extent in different packing houses.

A modification of the above method consists in exhausting the cans in vacuo and automatically sealing them in the exhausted state, thus removing all air and other gases therefrom. The cans are then placed upon an endless conveyor and dipped into an oil bath at a temperature of 240 degrees, the speed of the conveyer being so regulated that the cans remain in the bath a sufficient length of time to complete sterilization before being carried out at the opposite end. After passing through this bath they are carried automatically into another bath consisting of a solution of carbonate of soda and, finally, into a bath of pure water. The cans are then painted and labeled as originally described.

SPECIAL STUDIES OF METHODS OF CANNING BEEF MADE IN BUREAU OF CHEMISTRY.

=Composition of Beef Used for Canning.=--Samples of fresh beef intended for canning purposes, and examined in the Bureau of Chemistry, have the following composition:

Water, 71.17 percent Insoluble protein, 13.87 „ Globulins, 1.38 „ Proteoses, peptones, and gelatin, 1.31 „ Meat bases, 1.09 „ Fat, 9.89 „ Ash, .96 „ Salt, .04 „ Undetermined, .33 „

The sample, of which the above data are representative, was secured from a mass of meat weighing 356 pounds, after passing through a sausage grinder and being thoroughly mixed. The above data may therefore be regarded as the representative constituents of the usual grade, most carefully selected canning beef.

=Effect of Parboiling.=--A similar lot of meat secured in the same way and from the same carcass weighed 358 pounds and was parboiled as follows: The meat was placed in water in a steam-jacketed tank, the temperature of which stood at 196 degrees F. The reduction in the temperature caused by the meat was restored by heating the contents of the retort, and it was kept at 196 degrees F. for 15 minutes. It is thus seen that this parboiling was accomplished at a temperature below the boiling point of water. After the parboiling was completed it was found that the meat weighed 235 pounds, showing a net shrinkage in weight of 123 pounds. This sample of meat was then tinned in two-pound cans with the addition to each can of two ounces of canning jelly of the following composition:

Water, 95.18 percent Protein, 1.75 „ Common salt, 2.85 „ Ash, .22 „

After sterilizing, the cans were opened and the contents subjected to analysis. The data obtained are as follows:

Water, 62.47 percent Total protein, 24.88 „ Insoluble protein, 22.25 „ Proteoses, peptones, and gelatin, 2.63 „ Meat bases, 1.15 „ Fat, 9.87 „ Ash, .91 „ Salt, .19 „

Composition of Parboiling Water.--The liquor, after parboiling the above sample, weighed 280 pounds and had the following composition:

Water, 99.12 percent Protein, .06 „ Meat bases, .25 „ Ash, .25 „ Salt, .05 „

The above data show that the general effect of parboiling upon the canned meat is to diminish its content of water. Only a small quantity of the soluble proteids is found in the liquor, and the other principal constituents removed, aside from water, are the meat bases and mineral content or ash. The fat in the soup liquor was not determined because it rises to the surface and is not in any sense a constituent of the liquor itself. Considerable quantities of fat were removed in parboiling, the amount depending largely upon the temperature. At a low temperature of parboiling, such as described, the amount of fat secured is far less than when the temperature of parboiling is higher.

TABLE SHOWING THE COMPARATIVE EFFECT OF PARBOILING AND STERILIZING UPON THE FRESH BEEF.

----------+-----+---------+--------+----------- | | |COMPOSITION | | | | OF CANNED | | | | BEEF AS | |EXTRACTED| |DETERMINED |FRESH| BY |ADDED IN| BY CONSTITUENTS.|BEEF.| BOILING.|CANNING.| ANALYSIS. ----------+-----+---------+--------+----------- | Lbs.| Lbs. | Lbs. | Lbs. Water, |254.8| 122.1 | 14.1 | 146.8 Protein, | 59.3| .1 | .1 | 58.5 Meat bases, | 3.9| .7 | .0 | 2.7 Fat, | 35.4| 12.2 | .... | 23.2 Ash, | 3.4| .7 | .2 | 2.1 Salt, | .1| .1 | .2 | .4 Undetermined,| 1.2| .... | .... | 1.7 |-----| ----- | ----- | ----- Total, |358.1| .... | .... | 235.4 ----------+-----+---------+--------+-----------

Preparation of Canned Beef with More Intensive Parboiling.--In another experiment, determining the effect of the changes produced upon the fresh meat, more vigorous preparatory operations were performed. Samples were secured from eight healthy carcasses for use in this determination. Half of the sample was reduced to sausage and secured for analysis as described, and the other submitted to parboiling, sterilizing, and analysis.

COMPOSITION OF THE SAMPLE OF FRESH MEAT.

Water, 69.33 percent Total protein, 16.81 „ Insoluble protein, 12.69 „ Globulins, 3.06 „ Proteoses, peptones, and gelatin, 1.06 „ Meat bases, 1.12 „ Fat, 10.68 „ Ash, 1.13 „ Salt, .24 „

The original sample represented over a thousand pounds. The opposite sides of the carcasses were prepared for canning and produced the following amount of articles as sold on the market:

Total weight of half carcasses, 1,761 pounds 3 ribs, 53 „ 5 rolls, 43 „ 5 loins, 166 „ 3 tenderloins, 13 „ 3 sirloin butts, 28 „ 3 boneless strips, 24 „ 8 rump butts, 36 „ 8 flank steaks, 8 „ 8 kidneys, 9 „ 24 beef hams, 261 „ Shank meat, 85 „ Soft bones, 198 „ Shank bones, 107 „ Tank tallow, 132 „ Canning meat, 598 „

The above data show that only about one-third of the whole carcass is suitable for canning purposes. The best and juiciest pieces, it is noticed, are cut away and sold for other purposes. In explanation of the above data it should be stated that only the fore-quarters of the carcass were used and not the whole carcass.

In the preparation of the sample for analysis, the same selection was made as for canning, and only the canning meat was used in the preparation of the sample.

Parboiling.--The parboiling of this sample was accomplished in the following manner: The meat was first placed in cold water, 50 degrees F., and heated by means of injected steam. In five minutes the temperature had reached 122 degrees F., and at the end of eleven minutes the boiling temperature was reached and continued for one hour. The soup liquor resulting from the parboiling weighed 1,500 pounds and had the following composition:

Water, 99.08 percent Protein, .09 „ Meat bases, .23 „ Ash, .28 „ Salt, .11 „

These data show that, as in the other cases, the chief extraction from the meat during parboiling is water and the next most important removal is of meat bases and mineral matter or ash. After sterilization in the usual way the cans were opened and the canned beef subjected to analysis. The composition of the canned beef was as follows:

Water, 56.18 percent Total protein, 31.57 „ Insoluble protein, 27.94 „ Proteoses, peptones, and gelatin, 3.63 „ Meat bases, 1.44 „ Fat, 7.72 „ Ash, .82 „ Common salt, .04 „

Composition of the Fresh and Canned Meat.--Below is found a table similar to that already given for the other sample, showing the composition of fresh beef and the resulting canned beef.

----------+-----+---------+--------+----------- | | |COMPOSITION | | | | OF CANNED | | | | BEEF AS | |EXTRACTED| |DETERMINED |FRESH| BY |ADDED IN| BY CONSTITUENTS.|BEEF.| BOILING.|CANNING.| ANALYSIS. ----------+-----+---------+--------+----------- | Lbs.| Lbs. | Lbs. | Lbs. Water, |414.6| 243.2 | 12.9 | 184.3 Proteins, |100.5| 1.3 | .... | 101 Meat bases, | 6.7| 3.4 | .... | 4.6 Fat, | 63.9| 39.2 | .... | 24.7 Ash, | 6.8| 4.2 | .... | 2.6 Undetermined,| 5.5| .... | .... | 2.8 |-----| ----- | ----- | ----- Total, |598 | .... | .... | 320

From the above table it is seen that the shrinkage during parboiling amounts to 46.49 percent of the weight of the fresh meat. Of this shrinkage 82.85 percent is water, 14.11 percent is fat, 1.51 percent ash, and 0.82 percent meat bases. It is noticed that more than half of the water originally found in the meat is extracted by parboiling.

It seems rather anomalous that boiling a substance with water would extract water from it, but in the case of meats it is seen that half the water, or even more, which a meat contains is extracted from it by boiling in water.

The two samples given are extreme cases in the method of preparing meats for canning. In the first instance the meat is placed at once into hot water just below the boiling point and kept there for only a short time. In the second case the meat is placed in cold water and is brought to the boiling point and maintained there for one hour. In the last case the low temperature of the water in which the meat was originally placed favors the extraction of a portion of the soluble protein matter, namely, albumins, globulins, etc., while, on the other hand, the long-continued boiling to which it was subjected tends to decompose the connective tissues of the meat and causes the loss of small particles of the insoluble protein thus separated by disintegration. Although in the last case the shrinkage was much greater than in the preceding experiment, practically no insoluble protein matter was extracted, mechanically or otherwise.

Canning of Beef without Parboiling.--To determine the amount of shrinkage which takes place and the general effect which is produced by canning meats without parboiling, samples were prepared, sterilized, and canned in the usual way, with the exception of the omission of parboiling. On opening the cans it was found in each case that the meat had shrunk to about two-thirds of its former volume and that the place was occupied by a liquid containing a number of particles of solid matter. The appearance of the sample was much less inviting than that of meat canned after parboiling.

An analysis of the sample was made, with the following results: Total weight of sample, 31 ounces; weight of canned meat, 21 ounces.

Water, 63.83 percent Protein, 27.25 „ Meat bases, 1.09 „ Fat, 4.62 „ Ash, 1.01 „ Salt, .04 „ Undetermined, 1.20 „

Composition of Liquid.--The liquid in the can was examined with the following result: Weight of liquor, 10 ounces.

Solids, 6.93 percent Protein and gelatin, 1.94 „ Meat bases, 1.84 „ Ash, 1.22 „ Salt, 1.15 „

The above data show that the beef lost 32.06 percent of its weight in the canning, a little over half of which is water.

It appears that less protein matter is extracted when the meat is parboiled by being plunged into boiling water than when it is packed in a can without parboiling and subsequently subjected to the temperature of sterilization. In the former case the soluble

proteins in meat near the surface are coagulated before they can diffuse into the surrounding water. In the other case, owing to the low conductivity of meat, the temperature at the surface of the can penetrates slowly to the interior and the juices which are extracted from the meat carry with them protein matter in solution which is afterwards precipitated by heat and remains in the liquid as matter coagulated at the temperature of sterilization.

It is seen that parboiling has many advantages. It extracts less of the valuable matter from the meat, it shrinks the meat before packing so that the tins contain more nutrient matter, and it improves the appearance of the meat to the consumer when opened.

=Relation of Canned to Fresh Meat.=--In the following table is given the number of ounces of canned meat in a number of cans compared with the equivalent amount of fresh beef used in filling them:

NO. OF CAN. CANNED BEEF, EQUIVALENT TO FRESH BEEF. Ounces. Ounces. 1, 29 44.2 2, 29.9 42.6 3, 28.5 38.7 4, 12.6 19 5, 30.5 57 6, 30.6 50.9 ---- ---- Means, 26.9 42.1

It thus appears that a can of 26.9 ounces of beef contains, as an average content, an amount of meat equivalent to 42.1 ounces of fresh beef, and retains practically all of the nutrient value of the larger quantity of fresh beef.

=Canned Ham and Bacon.=--It seems unnecessary, as a rule, to can ham and bacon properly cured and transported in a suitable manner. There are occasions justifying the use of these products in tropical countries and in other places far remote from the sources of manufacture, and where the preservation of them, by reason of the character of the climate, is difficult.

The proper preparation of these articles, packing in tins and sterilizing, makes it possible to send them to the most distant points and to have them consumed in the most unfavorable climatic conditions. Canned ham, as it is found upon the market, has a higher percentage of fat and a consequently lower percentage of protein than canned beef. The ham is packed closely and the smaller pieces added for the purpose of filling up interstices between the larger pieces of meat and keeping the can full. It is reasonable to infer that the added meat is pork, although very probably it may not always be so.

=Composition of Canned Ham and Bacon.=--The character of the canned ham and bacon upon the market may be illustrated by the composition of the following samples (these samples were purchased in the open market and are presumably representative of the products as commonly sold in the shops):

COMPOSITION OF CANNED HAM AND BACON.

=Examination of Fat as a Test for Adulterations.=--It is evident, from what has already been said, that the character of the fats which are used in the canning of preserved meats is not always the same as that of the meat to which they are added. A careful study has been made in the Bureau of Chemistry of the fats extracted from different canned meats. The chemical and physical characteristics of these fats are given in the following table:

---------+---------+---------+---------+---------+--------- SOURCE | MELTING | CHILLING| IODIN |MAUMENÉ |DEGREES BUTYRO- OF FAT. | POINT. | POINT. | NUMBER. |NUMBER. | REFRACTOMETER. ---------+---------+---------+---------+---------+--------- | C.° | C.° | | C.° | Canned roast | | | | | beef, |36.5-43.9|27.8-37.0|36.1-50.6|35.6-36.0| 47.0-55.5 Canned smoked| | | | beef, |37.7-41.8|22.0-29.0|50.9-57.5| .. | 51.0-58.5 Canned ham | | | | | and bacon, |23.6-30.5|17.5-24.0|48.5-68.2|39.8-43.5| 49.0-58.2 Fowl, |28.0-34.0|12.0-36.5|67.0-86.4|38.9-52.0| 49.0-62.5 ---------+---------+---------+---------+---------+---------

It has been noticed that the crystals deposited by the evaporation of the ether solution of chicken fat resemble beef stearin in shape, but are much smaller and more delicate. It is seen that the melting point of fat in ham and bacon is rather lower than in leaf lard. It is evident, therefore, that this fat is not lard or, at least, not wholly composed of the best lard, but probably consists of the fat not usually employed for lard making.

=Potted Meats.=--There is found on the market a large number of varieties of potted meat. It is difficult to describe in any scientific way these potted meats because the term “potted” is employed by all manufacturers to describe a mixture of a great many different articles, the exact composition of which is usually a trade secret. There is, apparently, an understanding among manufacturers that the labels of potted goods are not intended in any way to indicate the variety of meat or principal meats contained in the package. In the absence of any trade, sanitary, or chemical standard it is difficult to make any just criticism of the character of the potted goods upon the market.

The principal object of mentioning them here is to inform the consumer of the probable character of the potted goods which he may consume, and to let him understand that it is by no means certain that the name of the meat upon the label describes the character of the meat which he is actually eating. The chief object in the manufacture of potted meat is to make a supply of uniform character and consistency, and properly spiced and flavored to attract and hold the patronage of the consumer.

A certain degree of consistency is established by each manufacturer for each variety of potted goods made, and to obtain this consistence more or less fat meat of some kind is added. It may thus be of some advantage to add the fat of pork rather than the fat of beef or mixtures of the two. It is claimed by many manufacturers that a single kind of meat does not give the desired flavor in potted and deviled goods. Therefore, meats of different origin are finely ground and mixed together, and a sufficient quantity of oil or fat added to secure the required physical consistence. For this reason cured meats, such as beef and pork, are often preferred for making potted and deviled meats because of the agreeable flavor and aroma which they impart thereto. These meats are therefore used in potting, although they cost more than corresponding quantities of fresh meat. In a character of goods so variegated as these it is impossible to lay down any rule which may guide the consumer in his choice. The widest latitude is left to the manufacturer, and the only real protection is in a strict inspection of the factory or factories where such goods are made. It is there only that the character of the materials employed and the quality of the condiments or other substances added can be determined. The day is doubtless rapidly approaching when consumers will be perfectly protected in this matter, and when no canned, potted, or deviled meats of any description will be allowed to enter into commerce without bearing the certificate of competent inspection officers as to the kind of meats used, their sanitary character, etc.

Potted meats should always be carefully sterilized and the contents of the tins should be consumed as soon as possible after they are opened.

=Potted Beef.=--Potted beef, more than any other product bearing the label of potted, corresponds more closely to the character of the meat named on its label. Of four samples of commercially potted beef examined in the Bureau of Chemistry only one appeared to contain any other meat than beef. The composition of the potted beef is shown in the table on page 53.

=Adulteration of Potted Beef.=--From the average data given above it is seen that the principal adulteration in potted beef, assuming that the meat is beef, is starch. Two of the four samples contained starch, one more than 14 percent and one more than 11 percent. The admixture of starch is evidently solely for fraudulent purposes, to increase the weight and bulk with a very much cheaper substance and one for which no necessity for the addition can be claimed. It also increases the quantity of water which the

product will carry. Saltpeter was found in one of the four samples and boric acid in two. One of the samples contained a large quantity of tin, due probably to the action of the potted meat upon the tin lining of the can.

=Potted Deviled Meats.=--The term “deviled meat” is applied to a mixture of finely ground meat with spices, condiments, and other substances, and, like the term “potted,” is used rather to indicate a miscellaneous mixture than any single compound.

All that has been said respecting the composition of potted meat applies with equal force to deviled meat. If there be any difference at all it is understood by the term deviled that the spices and condiments are more pronounced in character and greater in quantity and the miscellaneous character of the goods more pronounced. Under the terms of “deviled” and “potted” may be found every kind of mixed and miscellaneous finely comminuted meat, flavored with all kinds of condimental substances and prepared so as to appeal as strongly as possible to the taste and desire of the consumer.

accompanied by an official certification that it has been inspected and found to be up to the standard. It is only in this way that the public can be protected against fraud and imposition. Where no descriptive word at all is used with the word pâté there is no reasonable limit to be placed upon the kind of meat used, provided it is of a sound and sanitary character. The term pâté itself means a mixture and, therefore, it is no deception and imposition upon the public to sell a pâté of a miscellaneous character, provided it does not bear any false statement regarding origin or character.

The mean composition of forty-three samples of pâtés and purées is found in the following data:

Water, 45.87 percent Water in fat-free substance, 71.18 „ Fat, 35.41 „ Protein, 11.92 „ Meat bases, .82 „ Starch, 7.44 „ Total ash, 2.88 „ Of which sodium chlorid, .97 „

From the above data it is seen that the pâtés are characterized by a very high percentage of fat and a correspondingly low percentage of protein. A very large majority of the samples examined contained starch, the highest quantity found being 15.80 percent. Only two of the samples were found to contain saltpeter; six contained boric acid and three benzoic acid. Tin and zinc were found in a few cases.

=Principal Adulterations of Mixed, Miscellaneous, Potted, Deviled, and Comminuted Meats.=--As has been observed in the analyses of the commercial articles which have been submitted it is evident that no detection of the adulteration of these minced meats with impure fragmentary, diseased, or unwholesome articles is possible in so far as chemical analysis is concerned. A microscopic analysis also often fails to reveal the true character of the meats which have been used in the preparation of these bodies. Hence the adulteration of these bodies with diseased, unwholesome, unfit, and unsanitary meats cannot be controlled nor even positively affirmed after the meats are prepared and canned. Such adulterations are doubtless frequent and are the most objectionable. The only protection to the consumer is in a certificate of inspection before preparation and packing. The consumer, by refusing to purchase such comminuted meats in the absence of such a certificate, would soon compel the manufacturer to secure official inspection and certification of his products.

=Adulteration with Starch.=--One of the chief adulterants in sausages and prepared meats is starch. It has been said by some hygienists that starch is not an objectionable adulterant on hygienic grounds. This, however, is not strictly true. The injection of large quantities of starch into meat tends to unbalance a ration which is fixed with certain quantities of other food and tends to increase the proportion of starchy matter therein. There are many conditions of disordered digestion in which such increases of starch, unknown to the physician or patient or even known, are highly objectionable. Hence the use of starch as an adulterant in meat of this kind is reprehensible on hygienic grounds. The principal purpose for using starch is deception. Starch increases the bulk and weight of goods, and, in the process of cooking, prevents undue shrinkage. The consumer, therefore, thinks that he has secured a larger quantity and better quality of meat than he really has, and is, to this extent, defrauded and deceived.

=Preservatives.=--The preservatives which are principally used in meat are borax, boric acid, sulfite of soda, and benzoic acid. All of these preservatives have been shown, by researches in the Bureau of Chemistry, to be deleterious to health. They should be rigidly excluded from all meat as well as other food products.

=Coloring Matter.=--Dyes are frequently used for coloring sausage and other minced meats. All such dyeing materials are reprehensible, both on account of the danger to health and deception. Preserved meats gradually lose the natural red tint of the fresh meat, and to that extent the color is an index of the time during which they have been preserved. Inasmuch as consumers prefer fresh meats preserved as short a time as possible, they are deceived and to that extent injured by the use of dyestuffs which impart to preserved meats a fresh appearance.

=Indirect Coloring Matter.=--Certain chemicals, which of themselves have no color, serve to fix and hold, or even accentuate, the natural color of meat. The two principal chemicals used for this purpose are saltpeter and sulfite of soda. Saltpeter is used generally in preserved meats to retain and accentuate the red color thereof. Sulfite of soda is used principally on fresh meats, where it acts both as a preservative and as a retainer of color. Sprinkled over the freshly cut surface of fresh meat, sulfite of soda preserves the red tint, and the customer thinks it has just been cut. In this way he is deceived. Both of these substances are highly objectionable not only on account of deception but on account of being injurious to health. In the case of saltpeter, the general opinion concerning its therapeutic action is that it is not a proper substance to mix with foods. It would be highly desirable on the part of the packer, if he deemed it necessary to use bodies of this kind, to plainly state upon each package the character and quantity of preservatives and coloring matter employed. The consumer is then left to judge for himself whether or not he desires to eat these bodies.

The principal objection to notifications of this kind is that the consumer, not being an expert as a rule, cannot form any intelligent opinion respecting the desirability of these substances in food. He is more apt to be guided by common practice in this matter and by his own opinion than by any general principles of chemistry and hygiene.

=Potted Tongue.=--The term “potted tongue” may apply equally to tongue of a single character, such as beef, lamb, pork, or swine, or the mixture thereof. The examinations which have been made of the potted tongues of commerce do not indicate whether they are of a single character or whether the tongues are derived from a variety of sources. The mean composition of twenty-one samples bought in the open market, as found in the Bureau of Chemistry, is given in the following table:

Water, 52.50 percent Water in the fat-free substance, 67.67 „ Fat, 22.99 „ Protein, 17.80 „ Meat bases, .75 „ Total ash, 5.46 „

Adulteration of Potted Tongue.--In the samples examined above starch was found in four cases, the largest amount being 11.6 percent. Saltpeter was found in eighteen cases, the largest amount being .06 percent. Tin was present in thirteen cases and zinc in eight cases. Boric acid was found in fourteen cases.

From the above it is evident that the principal adulterations in potted tongue, aside from the use of meats which are not tongue, and which chemical analysis cannot disclose, are the addition of starch, saltpeter, tin, and zinc, the two latter derived either from the solder or from the can in which the goods are placed.

=Canned Poultry.=--Other fresh meats, in addition to beef and pork, are canned in a fresh state. In the case of poultry the fowls are dressed and drawn and the whole carcass boiled until the meat is sufficiently cooked to facilitate the separation from the bones. The bones are then removed and the meat is canned and sterilized by practically the same method as practiced with canned beef. Game and wild fowl meats are also subjected to the same process of canning as the domesticated chickens, geese, ducks, turkeys, etc. In general it may be said that there are no differences in the processes employed, but the important question to the consumer is the character of the raw materials used, the sanitary conditions which attended their preparation, and their freedom from admixtures of other meats cheaper in price and of different dietetic values.

=Adulteration of Canned Fresh Meat.=--Fortunately the process of sterilization is of such a character, when properly carried out, as to exclude all necessity for the addition of any preservative substances to canned fresh meat. The use of ordinary condimental substances in moderate quantities cannot be regarded as an adulteration. Hence, the addition of small quantities of salt, sugar, vinegar, and the ordinary spices, when used solely for the improvement of the taste and flavor and not for preservative purposes, is regarded as unobjectionable.

The common preservatives used in canned meat are, first, those which give color to the meat and preserve its natural red tint. For this purpose saltpeter and sulfite of soda are most commonly employed. Red dyes of any description are rarely, if ever, found. The preservative which is used most frequently in canned meat is borax or boric acid. That this use is not necessary is evident from the investigations which have been made in the Bureau of Chemistry which show that in most cases no preservatives at all are used. The addition of any chemical preservative is, therefore, to be regarded as unnecessary and as an adulteration.

The use of any diseased, tainted, decomposed, or filthy meat, even if it is of the same origin as that in the can, is an adulteration of the most serious character and which can only be effectually controlled by the inspection mentioned above. The adulteration of the meat of fowls of all descriptions by cheaper meats, such as pork or veal, even if they be of wholesome and sound character, is an adulteration said to be often practiced and one which it is difficult to detect if the particles of meat are finely comminuted.

=Standard for Preserved Meats.=--The standard for preserved meat is the same as that for fresh meat which is given in the Appendix (Circular 19, Office of Secretary, Department of Agriculture). The meat must be sound, wholesome, clean, freshly taken from the slaughtered animal, and not one that has died from disease, suffocation, or otherwise, and must conform in name and character to the meat of the animal.

=Frequency of Adulteration.=--The examination made of numerous samples of canned meat in the Bureau of Chemistry shows that the adulteration of these foods is rather common but by no means general.

=Canned Horse Meat.=--Horse meat is commonly used for human food in many European countries, although it is believed that it is not used to any extent in the United States. When procured from healthy animals in a proper way there is no hygienic objection to

its use, though it is considered to be somewhat tougher than the flesh of other animals more commonly employed as food, but that is probably due to the fact that horses are not raised for food purposes and are usually not used for such until they are worn out in domestic service. There are many sentimental and often religious objections to the use of horse meat, but experience has shown that it is wholesome and nutritious. Horse meat is characteristic in containing more natural sugar, commonly known as glycogen, than any of the other ordinary meats used for human consumption. It approaches in its content of sugar some of the shell-fish flesh, such as that of the lobster. Practically all of the horse meat which is prepared in this country is exported to Europe. There are cases, however, on record of the sale of horse flesh to domestic consumers. Especially could it be used in this way in the form of sausage or other finely comminuted products without much danger of detection.

=Composition of Horse Meat.=--A number of samples of horse meat of undoubted origin and wholesomeness have been examined in the Bureau of Chemistry and the data tabulated. The average composition of sixteen samples of horse meat, representing different parts of the carcass, is shown in the following table:

Water, 69.81 percent Water in fat-free substance, 76.91 „ Fat, 9.61 „ Protein, 19.47 „ Protein insoluble in water, 14.83 „ Gelatinous protein, 1.23 „ Meat bases, 1.70 „ Glycogen, 1.82 „ Ash, 1.01 „

Composition of Dry Material.--

Protein, 67.98 percent Fat, 27.71 „ Ash, 3.18 „ Undetermined, 1.13 „

The high percentage of glycogen in horse meat is one of the safest methods of determining its character when comminuted or cut up into pieces so small as not to be identified by the usual anatomical characteristics. Very few other kinds of edible flesh contain as much as one percent of glycogen. Glycogen is a transitory product which tends naturally to be broken up into other substances, and, hence, even in horse meat after slaughter, it may rapidly disappear and thus, unless the meat is examined at once, very little glycogen may be found in it. A safer test for horse meat is in the nature of the fat therein. This fat does not tend to change as the glycogen does, and, therefore, in a pure preparation of horse meat even in a finely comminuted state the separation and examination of the fat will lead to a determination of the character of meat employed. The fats of horse meat have a lower melting point, a higher iodin number, and a higher heat value when mixed with sulfuric acid than those of beef.

Indeed, these differences are so marked as to afford a ready means of detection to the practical chemist. Even in the mixture of horse meat with other meat the variation in the character of the fats will be such as to lead to a correct judgment respecting the approximate amount of horse meat which has been used, provided it forms any notable amount of the mixture.

=Canned Cured Meats.=--Sterilization is such a certain method of preventing the decay of meats that it has now come into use to a large extent in the final preservation of shipments of cured meats. The object of curing, as has already been stated, is not merely to prevent the meat from decaying, nor is it intended to inhibit entirely enzymic action. On the contrary, if the method of curing were such as to entirely stop fermentative action, the flavors and aromas of preserved meats, upon which their value so much depends, would be eliminated, and we would simply have a mass of tasteless meat, preserved from decay by the application of chemical preservatives of a character to impart neither flavor nor aroma to the meat and at the same time prevent the activity of the various ferments above described. Such methods of preparation, naturally, should never be of general use, because in cured meats the consumer demands the flavor which naturally proceeds from the ordinary method of curing. After curing and when subjected to transportation the meats may undergo decomposition and reach their destination in a spoiled state. To avoid this it has been a customary practice to pack the meat in a chemical preservative, such as borax. This is, however, a very objectionable practice because even in the cured state the meat is still absorptive, and the borax, which is packed externally upon it, as a precaution during transit, must necessarily penetrate to a certain extent to the interior of the meat. By packing cured meat in tins and subjecting these tins to sterilization complete immunity from decay may be secured and there is no damage done to the aroma or flavor. We, therefore, find upon the market at the present time in tinned, canned, or potted form almost every variety of meat that is used either in a fresh state or after the usual method of curing.

=Canned Sausage.=--One of the most important of cured meats which is offered for sale is sausage. Sausage may be canned either in the fresh or cured state and, of course, may be adulterated in both conditions. Canned sausage should have a clean bill of health from the local inspector the same as any other meat food.

There is, perhaps, more room for deception in the manufacture of sausage than in almost any other form of comminuted meat. When properly treated with condimental substances, such as salt, spices, vinegar, etc., sausages are highly prized as a food product, and justly so. In the canned state sausage should undergo no other manipulation than spicing and sterilization at a temperature necessary to kill all fermentative germs and prevent decay.

Composition of Canned Sausage.--Twenty-five samples of canned sausage examined in the Bureau of Chemistry had the following average composition:

Water, 58.51 percent Water in fat-free substance, 75.59 „ Fat, 21.82 „ Protein, 13.92 „ Protein insoluble in water, 11.37 „ Gelatinous protein, 1.21 „ Meat bases, .67 „ Ash, 2.86 „ Sodium chlorid, 1.02 „

The above data show that canned sausage differs from fresh meat largely in its composition, especially in the much higher content of fat and lower content of water which is found therein.

Adulteration of Canned Sausage.--The principal adulteration, as has already been stated, is in the admixture of meats of unknown and miscellaneous origin and possibly inedible in character. The degree of comminution to which sausage is subjected renders it difficult in the inspection of sausage itself to determine the character of the animal from which it is made. The study of the fat is the most useful guide in such cases. Presumably sausage is made almost exclusively of beef and pork, but, as a matter of fact, much which is not eaten under its own name may be found in sausage.

Next to the introduction of meat of an improper character the most important adulteration is the common use of starch. Starch is very much cheaper than meat, and its abundant use enables a greater profit to be made. It is highly esteemed, also, as a “filler,” on the ground that it prevents the shrinkage of sausage when fried. Starch granules under the influence of heat are gelatinous, holding moisture with tenacity and preventing shrinkage in bulk.

The presence of starch in sausage must be regarded as an unjustifiable adulteration unless the amount therein is plainly marked on the label of the package.

The use of preservatives in the curing of sausage is a very common practice and, hence, canned sausages are found to often contain boric acid or borax and sulfite of soda especially. Dyes of various kinds are also used in coloring sausage or its covering, largely of a coal tar origin.

The proper safeguard for the consumer in regard to the character of sausage is in the inspection of the factory. It is highly important that each municipality and state should have a rigid system for the inspection of sausage, and the sausage thus inspected should bear the certification of the kind of meat used and its general character. The presence of inspectors in factories would prevent the use of preservatives which, it has been shown by the researches of the Bureau of Chemistry, are prejudicial to health.

=Magnitude of the Meat Industry.=--According to the census of 1905, showing the results of the tabulation of the statistics of slaughtering and meat packing and slaughtering, wholesale, for the calendar year 1904, forming a part of the census of manufactures of 1905, which was taken in conformity with the act of Congress of March 6, 1902, the figures indicate that there has been a normal increase in the slaughtering and meat packing industry in the United States, as compared with the statistics of 1900, which covered the fiscal year ending May 31st.

Comparative figures for 1905 and 1900 are shown in the following summary:

PERCENT OF 1905. 1900. INCREASE.

GENERAL OBSERVATIONS.

It is evident, from the foregoing description of the methods of preparing and sterilizing meat, that it is a process which commends itself both on account of the economy in the use of meat which it secures and because of the nutritive value of the products obtained.

The real value of the products must necessarily depend upon the selection of the raw materials and the sanitary conditions which attend their manipulation. Experience has shown that it is not safe to leave these matters to the packers themselves. While, doubtless, the greater number of packers will exercise all possible care in the selection of the materials and in their preparation, human nature is of such a character that when opportunity for deception, fraud, and illegitimate gains are presented there are always some who take advantage of them. Hence, it may be safely said that no tinned or canned or sterilized meat of any description should be allowed to enter into consumption except when prepared under the inspection of qualified municipal, state, or national officers. The health of the animal furnishing the meat should be ascertained by inspection both before and after slaughter. This inspection should be of the most rigid kind, and all diseased animals should be excluded from entering into standard products. If it be claimed that there are certain diseases which are local only in character and which do not affect the wholesomeness of the whole carcass, special provisions can be made for this kind of meat. If admitted into consumption at all, it should be under a permanent label or tag by which the intended consumer would be informed of the character of the contents of the package.

There is a reasonable doubt respecting the suitability for human food of carcasses of animals afflicted in a moderate degree with tuberculosis, pleuro-pneumonia, lumpy jaw, or other contagious or epidemic diseases. In all such cases the rights of the consumers demand that the benefit of the doubt should be given to them and not to the owner, manufacturer, and dealer in any of the products they consume. Such meat would then enter the market under a separate grade and command a lower price, and when consumed no one would be deceived respecting its character.

It must be admitted, even if such meat be regarded as wholesome, that it is of inferior character, and cannot in any justice demand the right to pass under the name of higher grades of the article. The sanitary conditions under which such meats are prepared are of the highest importance. The slaughter house should be clean, and provided with good ventilation and natural light. The workmen should be free of disease, neatly dressed, and required to observe all necessary sanitary precautions. The débris and fragments of the packing house should be carefully removed and so disposed of as to prevent any suspicion that any part of them enters any of the products of the factory. Municipal, state, or national inspection should be frequent, thorough, and entirely removed from any possible influence of the packing business itself. Competent veterinary experts should pass upon the state of health of each carcass, and any one found diseased in any way should be subjected to a further careful inspection to see whether it should be admitted, under proper label and notification, as human food or consigned to the fertilizer heap. It is only by such inspection as this that the consumer can secure adequate protection. After the meat is once in the can inspection will only reveal whether or not preservatives and coloring matter have been used, or whether the contents of the can are spoiled or in a state unfit for consumption. No examination of the contents of the can will reveal in a satisfactory manner the state of health of the carcass from which the meat has been secured or the sanitary conditions under which it has been prepared. It is hoped the new methods of inspection established by the Secretary of Agriculture will secure the desired purity of meat products.

LARD.

The fat of swine, properly separated from the other tissues, is known as lard. The process of separation is termed “rendering.” Various methods of rendering are practiced, all depending, however, upon the use of heat, which liquefies the fat and gradually frees it from its connective tissues.

=Parts of Fat Used for Lard Making.=--In the making of lard the highest grades are produced from the fat lining the back of the animal and that connected with the intestines. The sheets of fat which are found lining the back of the animal furnishes a variety known as leaf lard. All parts of the fat of the animal not used in the meats themselves may be used in the manufacture of lard. In the preparation of the carcass, the parts cut off in trimming the pieces and containing fat are sent to the rendering tank. The leaf lard is

also removed by tearing it off from the back of the animal, and the intestinal fat is separated from the viscera in like manner. There is probably no question of wholesomeness between the lards made from different parts of the carcass. The lard differs in its chemical composition and its physical consistence as determined by its location in the body. Inasmuch as it is important that lard should have a certain degree of consistence even in summer time and not become too soft or liquid in character, the lard which has a high melting point is preferred, especially during the summer. The lards made from the feet and some other parts of the hog have lower melting points. The different kinds of fat from all parts of the animal might be mixed together and a lard made therefrom representing the average consistence of the fat of the whole body. A small quantity of stearin is often added to raise the melting point, but the addition of this substance without notice must be regarded as an adulteration.

=Names of Different Kinds of Lard.=--The names applied to the different kinds of lard may be referred principally to the parts of fat used, such as leaf lard, intestinal lard, etc., or to the method of preparing it. The old-fashioned method of preparing lard for family use consisted in placing the fat in an open kettle and heating usually over the open fire. The rendering takes place as the mass increases in temperature, so that the residual tissues become browned by the high temperature reached. Lard made in this way is of most excellent quality and, of course, being made under family supervision, its character is well understood and the parts of the body used are well known. In the large packing establishments the lard is usually rendered by the application of heat in the form of steam under pressure, of a suitable temperature to make the character of lard uniform. Large yields can be secured in this way with less charring of the residual tissues, and consequently a finer and whiter color in the lard itself. Lard of this kind is sometimes known as steam rendered lard.

=Uses of Lard.=--The fat of swine prepared as above mentioned, and known as lard, finds a very extended use in every kitchen. It is mixed with various forms of bread making materials, cake, etc., and is often known in this sense as “shortening.” It is also employed for lubricating the pans and other culinary utensils used for baking purposes. It is sometimes employed for the purpose of cooking by the process of frying or of introducing the substance to be cooked directly into the hot lard, as in the frying of oysters, the making of doughnuts, and similar operations. Lard has come to be looked upon as a necessity in every kitchen, even of the humblest citizen.

Many objections are made to the use of lard on hygienic grounds, and probably on account of its cheapness and general utility it is more freely used in American cooking than it should be. In other words, American cooking is under the reproach of being too greasy. There is no reason to question the digestive and nutritive value of lard when used in proper quantities and in proper conditions. It is a typical fat food composed of materials which are almost wholly oxidized in the body and which upon combustion produce a higher number of units of heat than that of any other class of food substances.

----------+-----+-------+------+-----+-------+--------+-------+------

=Adulteration of Lard.=--The principal adulteration to which lard is subjected is admixture with other and cheaper fats. Among the fats which are used for this purpose may be mentioned beef fat and cottonseed oil. Beef fat has a higher melting point than lard and cottonseed oil a much lower melting point, being liquid at ordinary temperatures. A mixture of beef fat and cottonseed oil may, therefore, be made, having approximately the same melting point as lard itself. The addition of this mixture to lard would not alter its melting point to any sensible extent. Instead of using the whole cottonseed oil for the purpose mentioned it may be previously chilled and its product of a higher melting point, or as it is sometimes called, the stearin of cottonseed oil, may be used for admixture with lard. Large quantities of these mixed fats were formerly made in this country under the name of “compound lard” in which the above adulterants were the chief constituents. The laws of the various states are happily of a character which forbids the sale of a mixture of a compound of lard and other fats under the name of lard, although there is no objection to such admixture from a hygienic and dietetic point of view. There are many hygienists who are of the opinion that the more extended use of vegetable oils instead of lard would be of value to the health of the public. If this be true, the admixture of a vegetable oil with lard would improve it

from a hygienic standpoint. The principal, perhaps the sole, objection to such admixtures is their fraudulent character. Vegetable oils, especially cottonseed oil, being very much cheaper than lard, their use in lard without notification cheapens the product and defrauds the customer. Lard may also be adulterated with its own stearin. In the manufacture of lard oil a residue is left of a much higher melting point and this residue may be mixed with a vegetable oil, such as cottonseed, in the production of a compound of approximately the same melting point as lard itself. In a case of this kind both constituents are fraudulent, in as much as neither the cottonseed oil nor the lard stearin may be regarded in any sense as lard.

=Detection of Adulterations.=--The presence of cottonseed oil in any form in lard is at once determined by the application of a simple color test known as the Halphen test. This is not a reliable test in those cases where the animal has been fed cottonseed.

Halphen Reaction for Cottonseed Oil.--Carbon disulfid, containing about one percent of sulfur in solution, is mixed with an equal volume of amyl alcohol. Mix equal volumes of this reagent and the oil under examination and heat in a bath of boiling brine for fifteen minutes. In the presence of as little as one percent of cottonseed oil an orange or red color is produced, which is characteristic.

Lard and lard oil from animals fed on cottonseed meal will give a faint reaction; also the fatty acids thereof.

This test is more sensitive than the Bechi test (nitrate of silver) and less liable to give unsatisfactory results in the hands of an inexperienced person. It is not affected by rancidity. The depth of color is proportional, to a certain extent, to the amount of oil present, and by making comparative tests with cottonseed oil some idea as to the amount present can be obtained, but it must be remembered that different oils react with different intensities, and oils which have been heated from 200° to 210° C. react with greatly diminished intensity. Heating ten minutes at 250° renders cottonseed oil incapable of giving the reaction.

Cottonseed oil also has the property of reducing silver in silver nitrate to a metallic state. When mixed with a solution of silver nitrate under proper conditions a blackening or precipitation of black metallic silver is observed. This is known as the Bechi test which is conducted as follows:

Bechi or Silver Nitrate Test for Cottonseed Oil.--_Reagent_: Dissolve 2 grams of silver nitrate in 200 cubic centimeters of 95 percent alcohol and 40 cubic centimeters of ether, adding one drop of nitric acid.

Mix 10 c.c. of oil or melted fat, 5 c.c. of reagent, and 10 c.c. of amyl alcohol in a test tube. Divide, heat one-half in a boiling water bath for ten minutes, and then compare with portion not heated. Any blackening due to reduced silver shows presence of cottonseed oil.

Other oils which have become rancid, and lards which have been steamed or heated at high temperature, contain decomposition products which have a reducing action on silver nitrate. There were found in testing a large number of salad oils some which contained no cottonseed oil, according to the Halphen test, but gave a brown coloration with Bechi reagent, and in some cases reduced silver. These same oils on being purified gave no reaction. Hence the oils or fats should be purified before testing.

To purify the oils and fats, heat from 20 to 30 grams on water bath for a few minutes with the addition of 25 c.c. of 95 percent alcohol, shake thoroughly, decant as much of the alcohol as possible, and wash with two percent nitric acid, and finally with water. The oil or lard thus purified will give no reduction at all if it contains no cottonseed oil. Heating the oils or fats to 100° C. or simple washing with two percent nitric acid is not sufficient, except in a few cases.

With oils the use of the Halphen and Bechi tests will be found to be useful as a means of approximately determining the amounts of adulteration present. If Halphen gives a reaction and Bechi does not, the adulteration with cottonseed oil is probably less than 10 percent.

The admixture of beef fat with lard is best detected by means of the microscope. The fat is dissolved in ether and allowed to slowly crystallize. If it is composed of pure lard the crystal assumes a form which is represented in Fig. 8.

If, on the other hand, beef fat be mixed with lard, the crystals will assume a radiated fan-shaped appearance shown in Fig. 9. Even one who is an expert with the microscope may not be able without some difficulty to detect these adulterations by the simple tests above mentioned.

[Illustration: FIG. 8.--LARD CRYSTALS. × 140.--(_Bureau of Chemistry._)]

[Illustration: FIG. 9.--BEEF FAT CRYSTALS. × 140.--(_Bureau of Chemistry._)]

=Commercial Classification of Lards.=--In addition to the kinds of lard mentioned above other varieties are known in commerce.

=Neutral Lard.=--This, which is one of the best varieties of lard, is made from the fat derived from the leaf lard of the slaughtered animal in a perfectly fresh state, that is, taken immediately after slaughter and before the carcass is cold. The leaf lard, when it is removed from the animal, is at once placed in cold storage or put into cold water, in order to rapidly remove the animal heat. As soon as it is thoroughly chilled it is reduced to a pulp in a grinder and sent at once to the rendering kettle. The fat is rendered at a very low temperature, from 105 to 120 degrees F. (40-50 degrees C). It is evident that only a part of the lard is separated at this temperature, and this part is regarded as being of the best quality, almost tasteless, free of acids and other impurities. The residue from the making of neutral lard is sent to other kettles, where it is subjected to a higher temperature and the remainder of the lard extracted, which is sold under the name of another grade. Neutral lard, obtained as above, while still liquid, is washed with water containing a trace of sodium carbonate, common salt, or a dilute acid. The product thus formed is almost neutral in its reaction to litmus paper containing not to exceed .25 percent of free acid, but it has more water and mineral matter than is found in the pure rendered untreated lard. The neutral lard made in this way is not used so commonly for culinary purposes but chiefly in the manufacture of oleomargarine.

=Leaf Lard.=--The residue of lard obtained by rendering the unseparated part of lard from the above process at a higher temperature is also of a high quality and is sometimes improperly designated leaf lard, a term which should be reserved for the whole product instead of a part obtained by rendering the residual leaf fat.

=Choice Kettle-rendered Lard.=--The amount of neutral lard which is demanded in the manufacture of oleomargarine does not by any means exhaust the supply of leaf lard. For making choice kettle-rendered lard the leaf lard together with the fat cut from the back of the animal is rendered in steam-jacketed open kettles and produces a lard of a high quality known as kettle-rendered or choice kettle-rendered lard. The hide is removed from the fat portion of the back used for this purpose before the rendering. Both the leaf and pieces of the back are passed through a fine sausage grinder before they enter the rendering kettle. According to the requirements of the Chicago Board of Trade, choice lard, which is another term for the above variety, is to be made from leaf and trimmings only, either steam-rendered or kettle-rendered, and the manner of rendering to be branded on each package.

=Prime Steam Lard.=--The prime steam lard of commerce is made as follows: The whole head of the hog, after the removal of the jowl, is used for rendering. The heads are placed in the bottom of the rendering tank. The mesenteric fat adhering to the small intestines is also used in the tank. Any fat that may be attached to the heart or other organs of the animal may also be used. In those factories where kettle-rendered lard is not made the scrap fat from the back of the animals and trimmings are also used. When there is an excess of leaf it is also put in the rendering tank and, in general, all the fat portions of the body which are removed in the trimming process. It is thus seen that prime steam lard is a term which may practically represent the average fat of the whole animal.

Prime steam lard is thus defined by the Chicago Board of Trade: “Standard prime steam lard shall be solely the product of the trimmings and other fat parts of hogs, rendered in tanks by the direct application of steam, and without subsequent change in grain or character by the use of agitators or other machinery except as such change may unavoidably come from transportation. It shall have proper color, flavor, and soundness for keeping, and no material which has been salted shall be included. The name and location of the renderer and the grade of the lard shall be plainly branded on each package at the time of packing.” All the lard which is made is subjected to the approval of inspectors both as to the material employed and the method of procedure, together with the character of the final product.

=Disposition of the Intestines of the Hog.=--In the term intestines is included all of the abdominal viscera of the animal but not the thoracic viscera, namely, the heart and lungs. The material is handled in the following way: When the animal is opened the viscera are separated, including the flesh surrounding the anus and a strip containing the external genito-urinary organs. The heart is thrown to one side and the fatty portions trimmed off for lard. The rest of the heart is used for sausage or for fertilizer. The lungs and liver are either used in the manufacture of sausage or for fertilizer. The rectum and large intestines are separated from the intestinal fat and peritoneum and, along with the adhering flesh and genito-urinary organs, sent to the trimmer. All flesh from the above-mentioned organs is cut away and the intestine proper is used for sausage casings. The trimmings, including the genito-urinary organs, are washed and placed in the rendering tank where lard is made. The small intestine is also separated from

the fatty membrane surrounding it and prepared for sausage casings. The remaining material, consisting of the peritoneum, diaphragm, stomach, and adhering membranes, together with the intestinal fat, constitutes the “guts” which are subjected to washing in three or four different tanks. In the first tank the stomach and peritoneum are split open, and also any portion of the intestines which still adhere to the peritoneum. The portions then go from tank to tank, usually four in number, and are then ready for the rendering tank. The omentum fat is cut from the kidneys, and the kidneys with any adhering fat go into the rendering vat. The spleen, pancreas, vocal cords, trachea, and œsophagus also go into the tank.

In general it may be said that everything connected with the viscera go into the rendering tank with the following exceptions: First, that portion of the intestines which is saved for sausage casings; second, the liver and lungs; third, that part of the heart free from fat.

In the killing of small hogs, where the intestines are not of sufficient size to be suitable for sausage casings, they also go into the rendering tank. It should be stated here that the grease or lard obtained by the rendering of the above described viscera, according to the statements of the manufacturers, is used solely in the manufacture of lard oil and soap, and does not enter into the lard of commerce.

When the processes of manufacture are properly controlled by official inspection the public may be assured that this disposition of the fat obtained by the rendering of the intestinal viscera is secured.

=Butchers’ Lard.=--A considerable quantity of lard is made for commercial purposes by the small butcher for family use, etc. This lard is made almost exclusively by rendering in the open kettle. In the country where butchering is conducted for family use the ordinary open kettle is placed over an open fire. All parts of the fat of the animal which can be easily separated and the scraps derived from trimming the animal are used for rendering. The offal and refuse of the animal are also rendered separately and the product used for soap grease. The lard made in this way is regarded as perfectly wholesome, but it is frequently dark-colored from the charring due to rendering over the open fire and by reason of using some portions of the animal, such as tendons, from which glue is made. Such lard may contain traces or even considerable quantities of glue which, however, cannot be regarded as an unwholesome product. The partially browned residues in the kettle in the country are known as “cracklings” and are used for soap grease.

=Inedible Hog Fat Products.=--In the shipping of hogs a great many are smothered and others die of disease or are in a condition, at the time of slaughter, which renders them unfit for human food, either by the presence of disease or otherwise. The fats are separated from dead animals of this class and are used for technical purposes such as burning oils, soap grease, etc. There are several varieties of these inedible fats of which the following are the principal:

White Grease.--This grease is made chiefly from hogs which die in transit by being smothered or from freezing. Formerly it was the custom to make white grease also from the animals which died of disease, but the manufacture of this product has been restricted by certain state laws which forbid the use of animals which die of particular diseases, such as hog cholera, from being used for any purpose whatever and their carcasses are to be buried so as to remove all danger of infection.

Brown Grease.--Brown grease is a product of a lower grade than white grease and is made usually by rendering the whole animal. It is one of the by-products in the manufacture of tankage from condemned animal carcasses, the tankage being used as fertilizer. Both white and brown grease are used chiefly in the manufacture of low grade lard oil and in the making of soap.

Yellow Grease.--Yellow grease is a product intermediate in value between white and brown grease. It is made chiefly from the carcasses of animals that die while on the packers’ hands. It is used for the same purpose as white and brown grease.

Pig’s-foot Grease.--A special variety of grease is made from pigs’ feet as a by-product in the glue factory. This grease is used also in making lard oil and soap. It is evident that these varieties of grease are only inedible varieties of lard, and through proper inspection the public is protected against the use of these varieties of grease in the edible product.

=Lard Stearin.=--Mention has already been made of the fact that by melting a fat and cooling it slowly towards its solidifying point, certain constituents of the fat which have a higher melting point separate first, leaving those constituents with a lower melting point still in a liquid condition. Those portions of an oil or fat which separate first under such conditions, are the constituents of the product which is known as stearin, while the part that remains liquid is the constituent known as olein. Lard stearin is made

principally for the manufacture of mixtures and is a by-product of the highest grade of lard oil. Lard stearin is made as follows: The lard is melted and kept in a crystallizing room at from 50 to 60 degrees F., until it is filled with the crystals of the separated stearin. The product is then wrapped in the form of cakes with cloth. Each package contains from 10 to 20 pounds. The cakes are then placed in a large press with suitable arrangements to facilitate the escape of the oil and maintain the low temperature. The pressure is applied very gradually at first, and as the process advances, with increasing power. The high grade oil obtained in this way is known as prime or extra lard oil and is used for illuminating and lubricating purposes. The resulting solid product, which is principally stearin, is used as one of the adulterants of lard, that is, in making a mixture which is sometimes called lard, composed of lard stearin and cottonseed oil.

[Illustration: FIG. 10.]

=Tanks Used for Producing Lard Under Pressure.=--There are various forms of tanks used for producing steam rendered lard. In the open kettle there is a jacketed arrangement by means of which steam, at the proper temperature, is made to act upon the contents of the inner kettle. In the closed kettle the steam may be applied in the form of a jacketed arrangement or introduced directly into the kettle. The residues which remain after the steaming is completed and after the lard has been drawn off are withdrawn from the conical lower portion of the kettle which can be opened for the removal of these residues. A typical kettle for rendering lard is shown in Fig. 10. The fragments of meat to be received are placed in the opening M which is then properly closed when the tank is full. Steam is admitted and the condensation which is produced at first by the cold contents of the tank is drawn off through a water pipe. After the tank is thoroughly heated and the fat begins to separate the lard will rise above the water and the solid fragments and at the end of the process will fill the upper part of the tank. By means of the cocks at D it can be determined to what depth the tank is filled with lard and the lard can be drawn off through these cocks until water begins to flow. The bottom of the tank at G is then opened and the residues withdrawn, dried and ground for tankage.

=Physical Properties of Lard.=--_Specific Gravity._--The specific gravity of pure lard is to be determined at some definite temperature, inasmuch as a statement of its specific gravity without some reference to the temperature at which it is determined is likely to be misleading. It is not convenient to ascertain the specific gravity of a lard at a temperature below its melting point. It is customary, therefore, either to take the specific gravity at about 40 degrees C., or at a temperature of boiling water.

The average specific gravity of pure lard at 40 degrees C. (104 degrees F.), regarding water as 100, is 89, and at 100 degrees C. it is 86, the weight of water being determined at the point of greatest density, namely, 4 degrees C. (39 degrees F.). Unfortunately the specific gravity of pure lard is not very greatly different from that of other oils or other fats used in its adulteration. For this reason it is not of the highest value for determining whether or not the pure article has been subjected to adulteration.

Melting Point.--The melting point of a pure lard is a physical characteristic of great value, since it is chiefly influenced by the part of the body of the animal from which it is made. The fat which is rendered from the foot of the hog has the lowest melting point, namely, about 35 degrees C. (95° F.). The fat adhering to the intestines has the highest melting point, namely, 44 degrees C. (111 degrees F.). The fat derived from the head of the hog has a slightly higher melting point than that from the feet. The kidney fat has a melting point of 42.5 degrees C. (108.2 degrees F.). In the steam rendered lards, representing the average of lards passed upon by the Chicago Board of Trade, the average melting point is found to be about 37 degrees C. (98.7 degrees F.). The melting point of superior or leaf lard has an average value of about 40 degrees C. (104 degrees F.).

Color Reaction.--A pure high grade lard when mixed on a white porcelain plate with the proper amount of sulfuric or nitric acid should give only a very slight coloration. The production of any considerable quantity of color, either brown or black, indicates the presence of organic impurities in the lard.

Rise of Temperature with Sulfuric Acid.--The various fats give different degrees of heat when mixed, under certain conditions, with strong sulfuric acid. It is possible to determine the approximate degree of the adulteration of lard by applying this test. The operation is a simple one and is conducted in the apparatus shown in Fig. 11. A common test tube about 24 cubic centimeters in length and 5 cubic centimeters in diameter is hung as indicated in the figure, provided with a stopper carrying a thermometer in the center with a bent glass rod stirrer passed loosely through the stopper on the side and a funnel for the introduction of the acid on another side of the thermometer. A coil which is on the stirring rod is so arranged as to permit the bulb of the thermometer to pass through its center.

[Illustration: FIG. 11.]

Manipulation.--Fifty cubic centimeters of the fat or oil to be examined are placed in the test tube and warmed or cooled, as the case may be, until the temperature is the one required for the beginning of the experiment, say 35 degrees C.; 10 cubic centimeters of the strongest sulfuric acid at the same temperature are placed in the funnel, the stopper being firmly fixed in its place; the test tube containing the oil is placed in a non-conducting receptacle; the wooden cylinder lined with cork, used in sending glass bottles by mail, is found to be convenient for this purpose. The glass rod or stirrer which fits loosely in the stopper, so as to be moved rapidly up and down, is held by the right hand of the operator; with his left hand he opens the glass stop-cock of the funnel and allows the sulfuric acid to flow in upon the oil. The glass stirring rod is now moved rapidly up and down, for about 20 seconds, thus securing a thorough mixture of the oil and acid. The mercury rises rapidly in the thermometer and after two or three minutes reaches a maximum, and then, after two or three minutes more, begins to descend. The reading is made at the maximum point reached by the mercury. With pure cottonseed oil, linseed oil and some other substances the rise of temperature is so great as to produce ebullition in the mass, causing it to foam up and fill the tube. To avoid this, smaller quantities of acid should be used or the oil in question be diluted with a less thermogenic one, so that the maximum temperature may not be high enough to produce the effect cited.

=Chemical Properties.=--_Volatile Acids._--The quantity of volatile acid arising on the decomposition of a soap made by the saponification of lard is very minute in lard of high quality. The total amount of volatile acid should not be in excess of that necessary to saturate .2 cubic centimeter of deci-normal alkali solution.

Fixed Acid.--The quantity of fixed acid, consisting principally of oleic and stearic, in pure lard should not be less than 93 percent. The total quantity of free acid in lard, that is, acid uncombined with the glycerine, should not exceed one-half of one percent, and in neutral lard should be much less than this.

Quantity of Iodin Absorbed.--All common fats and oils have the property of absorbing, under given conditions, certain quantities of iodin. Lard of the highest quality should not absorb more than 60 percent of its weight of iodin. The lard made from the feet and certain other parts of the animal, however, may have a larger iodin number, rising as high as 75 or even 80.

=Properties of Lard.=--The average properties of different classes of lard in relation to physical and optical conditions are shown in the following table:

RE- RISE OF TEMPER- SPECIFIC MELTING FRACTIVE ATURE WITH IODIN GRAVITY. POINT. INDEX. SULFURIC ACID. WATER. ABSORBED. 35° C. ° C. 25° C. ° C. PERCENT. PERCENT. .9053 40.7 1.4620 41.5 .077 62.48

The above table is the average composition of nineteen samples of lard furnished under affidavits of purity and which appear from their chemical and physical properties to be composed purely of the fat of swine taken from those parts of the animal usually devoted to lard making. The average data may be regarded as representing the properties of the ordinary pure commercial lard on the market.

=Average Properties of Steam Lard.=--Below is given the average composition of eleven samples of steam lard furnished under affidavit and, apparently, as judged by their chemical and physical properties, composed solely of the fat of swine. Steam lards are not of as high a quality as the lards contained in the preceding table. They have usually a distinctively strong odor, quite different from that of lards which are rendered in open kettles at low temperature and from selected portions of fat.

RE- RISE OF TEMPER- SPECIFIC MELTING FRACTIVE ATURE WITH IODIN GRAVITY. POINT. INDEX. SULFURIC ACID. WATER. ABSORBED. 35° C. ° C. 25° C. ° C. PERCENT. PERCENT. .9055 37.0 1.4623 39.9 .109 62.86

=Properties of Adulterated Lards.=--It is possible to mix together the different materials used in making adulterated lard in such a manner as to produce a compound which in some respects resembles the natural product. This compound, however, necessarily differs from the natural product in its physical and microscopic properties and in its reaction with various chemicals which give distinct color with the different fats and oils used as adulterants. The mean properties of thirteen samples of mixed or compound lards are shown in the following table:

RE- RISE OF TEMPER- SPECIFIC MELTING FRACTIVE ATURE WITH IODIN GRAVITY. POINT. INDEX. SULFURIC ACID. WATER. ABSORBED. 35° C. ° C. 25° C. ° C. PERCENT. PERCENT. .9060 40.6 1.4634 46.5 .098 63.58

These lards, in addition to the above properties, show distinct color reaction with sulfuric and nitric acid and with the reagents which are distinctive of cottonseed oil. They are mostly mixtures of lard and tallow stearin with cotton oil or cotton oil stearin.

In addition to the adulterations already mentioned as mixing with cottonseed oil may be added the use of coconut oil. It is not probable that in the United States any adulteration of lard with coconut oil has been made for commercial purposes. Such an adulteration, however, is practiced in some foreign countries. Coconut oil contains considerable quantities of volatile acid, and, therefore, when used as an adulterant of lard, would increase the normal quantity of volatile acid materially. One sample examined by Allen, of England, was found to contain a quantity of coconut oil, amounting to 33 percent.

=Summary.=--In the preceding pages has been given a description of the character of lard, the sources from which it is made, the method of its preparation, its chemical and physical properties and the common adulterations to which it is subjected. There is no question of the wholesomeness of the usual fats and oils, or parts thereof, which are used in the sophistication of lards. The adulteration is intended solely for fraudulent purposes, that is, to sell under the name of a higher priced article one of a lower price.

There are many persons who prefer to use vegetable oils and fats as substitutes for lard in all cases. It is only fair to the consumer that the character of a fat and oil, however, for edible purposes be plainly made known to the purchaser. He is then to judge of the propriety or impropriety of using the articles in question. It seems quite certain that the use of vegetable oils and fats will be greatly increased in this country. All hygienists grant that they are at least equally as wholesome as the animal fat and oil. They are certainly less open to suspicion as having been derived from diseased sources. As a rule, they are carefully expressed and properly refined, free from rancidity and from any mechanical or chemical constituents which render them unpalatable or unwholesome. They are generally much cheaper, perhaps the only exception being that of olive oil. These vegetable oils, as a rule, are excellent for salad dressing, for frying and general cooking purposes and for the ordinary uses to which lard and other animal fats are devoted. A proper labeling of all such packages would increase the quantity consumed, restoring confidence to the public in the character of the goods purchased, and prove of mutual benefit to the grower, the manufacturer and the consumer. It must be remembered, however, that there are many people who prefer the animal fats, and so there will probably always be a large field for their use. Such consumers are entitled to secure the pure article, properly prepared from healthy animals and free from rancidity and organic impurities. Lard and other animal fats offered in this way will have a greater vogue, command a greater degree of confidence and secure a larger trade than if sold under conditions engendering suspicion and distrust.

SOUPS.

=Classification of Soups.=--The soups which are commonly consumed are divided into two great classes--those of animal and those of vegetable origin. Any liquid or semi-liquid preparation of a meat or vegetable or the two combined which may or may not carry particles of solid substances is classed with these preparations. Soups are generally used at the beginning of a meal, usually at dinner-time, and, as a rule, do not have any very high nutritive value. That they have a useful function cannot be denied, since the introduction of a small quantity of a condimental and slightly nutritive warm liquid into the stomach at the beginning of dinner tends to stimulate the secretive glands of the stomach walls to greater activity and thus to promote digestion. Soup should be regarded pre-eminently as a condimental and not as a nutritive substance.

=Preparation of Stock.=--In the making of stock the base of the material, as a rule, is that part of the meat and bone soluble in hot water. The best way of preparing this stock is as follows:

The meat and bones selected should be fresh, free from all impurities and be derived solely from healthy animals as soon as they have been slaughtered. Inasmuch as the shape of the material used is of little consequence the parts of the carcass that are cut away in the preparation of the usual cuts of the marketable meats are utilized for stock making. The flesh should be cut into fragments of proper size and the bones broken up into small pieces. This material with the appropriate amount of water and salt is placed in a vessel capable of being closed in such a way that no aqueous vapor will escape, and a slight degree of pressure, equal to the half of an atmosphere, can be sustained. Simple forms of digesters are made for this purpose which are perfectly safe at low pressure and supplied with a safety valve so as to allow steam to escape if the pressure runs too high. Several hours of digestion are necessary for the preparation of stock, and if an ordinary vessel is used care must be exercised that the liquid does not evaporate so as to make the mass dry. Stirring from time to time assists the solution of the soluble substances. After the extraction is complete the liquid contents are poured off and the solid material pressed gently to separate the liquid held in solution. The mass is then put in a cool place and allowed to stand until thoroughly cooled and all the fat particles are collected at the top. The fat is then removed and the resulting liquid strained to remove any solid particles. The clear solution thus obtained is set aside and used

as stock in the preparation of the various forms of soups. When properly flavored and used by itself it produces the soup known as consommé.

The soup stock made in this way usually contains not less than 95 percent of water and not more than 5 percent of nutritive matter. Many of the clear soups prepared in this way contain very much less nutritive matter, sometimes as low as one percent. It is evident, therefore, that the soup stock is valuable as a condiment and flavoring and not as a food.

The number of soups which can be made from soup stock is practically unlimited. They are formed by the admixture, chiefly of vegetables cut into small pieces, of starchy materials, mashed peas or beans, particles of potato, fragments of parched bread, and in fact almost any nutritive and palatable substance which the cook may wish to employ.

A soup made from a stock of the above description with pea flour was found to have the following composition:

Water, 88.26 percent Protein, 3.38 „ Fat, .93 „ Ash, 1.13 „ Starch and other carbohydrates, 6.30 „

A soup made with potatoes from stock of the above description was found to have the following composition:

Water, 90.96 percent Protein, 1.37 „ Fat, 1.53 „ Ash, .99 „ Starch and other carbohydrates, 5.13 „

The French make soups which are very well known and highly valued by cutting vegetables, such as carrots, beets, radishes and other vegetable substances, into small pieces and adding them to the soup stock.

=Oyster Soup.=--A soup made of milk, cream, flour, condiments, oysters and the liquid of oysters is very largely eaten in the United States. The difference between oyster soup and oyster stew is chiefly in the amount of oysters employed.

=Green Turtle Soup.=--A soup stock prepared as above described and flavored with pieces of green turtle is a very common dish.

=Mock Turtle Soup.=--A soup made in imitation of a turtle soup in which veal takes the place of turtle for flavoring is known as mock turtle soup.

=Clam Soup or Clam Chowder.=--This is a soup made of clams in the same way that oyster soup is made. When the clams are cut into small pieces and are in great abundance and when potatoes are used in large quantities in the mixture it is known as clam chowder.

=Beef Extract.=--It is evident that a beef extract is only a soup or a soup stock specially prepared from beef. Beef extract first became known by the researches of the celebrated chemist Liebig, and has passed from a mere local preparation to an article which is important in commerce. Factories have been established in localities far removed from the principal markets of the world, but where cattle are extremely plentiful, as in South America, and the preparation of beef extract is carried on on a large scale, the meat of the animal being thrown away after the preparation of the extract. The method of preparing beef extract is practically that described for making a soup stock under pressure. Instead of using only the trimmings and refuse of the animal, however, usually the whole of the flesh is employed. The bones are sometimes used in the making of a beef extract. The sound, fresh meat is cut into small pieces and extracted under pressure as already described. After cooking and filtering the product it is brought, in vacuo, to a proper consistence. Meat extract is, therefore, simply a concentrated soup stock. It requires about thirty-four pounds of meat to yield one pound of concentrated extract, and this extract may be diluted for consumption so as to make from six to seven gallons of beef tea. The composition of the ordinary beef extract of commerce shows that it contains from 15 to 20 percent of moisture, from 17 to 23 percent of ash and from 50 to 60 percent of meat bases, that is, the soluble nitrogenous contents of meat. The bones and tendons are not used in making beef extract on account of the introduction of considerable quantities of gelatine into the material. Liebig does not recommend the presence of gelatine in beef extract because, being cheaper in quality, it is an adulteration of the genuine article, which should contain only the pure bases and not the gelatinous principle of the meat in the tendons and bones.

Character of Nitrogenous Bodies in Beef Extract.--When beef extract is prepared according to the Liebig method those nitrogenous bodies commonly known as meat bases are found in the concentrated extract. In a beef extract which contains a total of 9.28 percent of nitrogen the quantity of nitrogen in the form of nitrogenous compounds which were found therein is as follows: Nitrogen in the form of soluble albumin,--trace; in the form of albumoses,--1.17; in the form of peptone,--trace; in the form of meat bases,--6.81; in the form of ammonia compounds,--.47; in the form of unenumerated compounds,--.83. The chief meat bases which form the principal part of the substance are creatin, creatinin, xanthin, carnin and carnic acid.

There are many different forms of beef extract upon the market, sometimes called by fanciful names and sometimes by the name of the manufacturer. Among the fanciful names are some which indicate origin or kind. The extracts which bear the names of the manufacturers are very numerous, but all of these extracts are essentially of the same character. One of these is a meat extract in which some of the meat fiber is contained. The quantity of meat fiber which is used varies, but is not very great. A comparison of the dry substance in a preparation of the class mentioned above with the dry substance in meat shows the following relation:

ASH AND PROTEIN. MEAT BASES. MINERAL MATTER. Percent. Percent. Percent. Extract, 49.7 25.6 24.7 Meat, 86.7 7.8 5.3

The above data show that the extract is essentially different in its composition from dried meat and has added to it a large quantity of meat fiber or the meat rendered soluble by some kind of treatment.

Nutritive Properties.--It cannot be denied that meat extract, as has been said in the case of soup stock, contains only a small part of nutritive matter. This nutritive substance is in a state of solution and probably is more readily absorbed than a similar amount of other nutritives in the form of ordinary meat. Its chief value as a nutrient, therefore, is not in the amount of nutrient material which it contains, but in the ease and speed with which it may become absorbed into the circulation. In case of illness this is often a very important point. It is not a question so much of the utilization of a large amount of nutrients as the absorption and assimilation in small quantities which will sustain life until the disordered conditions disappear. For these reasons the meat extracts have a value. There is, however, little doubt of the fact that in the popular mind a great deal more credit is given to meat extracts than should properly belong to them. They must be regarded principally as condimental and incident to nutrition rather than as nutritive substances. The claims which are made by the manufacturers are sometimes misleading, as, for instance, that one pound of extract contains the nutritive properties of many pounds of meat. Such a statement, of course, is absurd upon its face and should not be allowed to go unchallenged. Even when meat extracts are reinforced by the addition of soluble or comminuted fiber, as is often the case, the quantity of nourishment is very small as compared with a similar weight of meat itself.

It is not intended by the above remarks to cast any discredit upon the value of beef extract, as its value has been attested in numerous cases. It is only designed to call attention to the fact that as food these extracts have comparatively little value. They may be useful as stimulants or as condimental substances or as a means of speedily introducing a soluble nutrient in the case of disease where it is extremely important that even small amounts of nutritious material should enter the body.

=Beef Juice.=--A distinction is made between a beef extract and a beef juice. The latter term applies solely to the liquid naturally remaining in the fresh meat after its proper preparation for consumption, that is, after the withdrawal of the blood and the proper cooling and storing of the flesh. The fresh meat is then subjected to strong pressure and the juices which are extracted are concentrated in vacuo to the proper consistence. The meat of old bulls is often used. A true beef juice must be extracted from the cold meat and not with the aid of heat, hot water or other solvents. It is difficult to preserve an extract of this kind without sterilization, and the heat required for sterilization is likely to coagulate some of the albuminous material which is expressed. It is a great temptation, therefore, in some cases to preserve the beef juice by a chemical preservative other than common salt. Boric acid and sulfite of soda may be used for this purpose, but these substances are objectionable on the score of possible injury to health. Glycerine is also used. Inasmuch as these juices are usually given to invalids or those whose digestive functions are impaired it is most important that injurious substances should be omitted. In case of pressure it is advisable, in some cases, to chop the meat very fine, and in this comminuted condition extract the juice with cold water. This does not produce any change in the character of the juice and the water is subsequently removed by evaporation at a low temperature in vacuo. Beef juices are usually prepared from heated meats.

Composition of Beef Juice.--The composition of beef juice from different parts of meat which was previously heated externally is shown in the following table.

COMPOSITION OF BEEF JUICE AND MEAT EXTRACT.

BEEF MEAT JUICE. EXTRACT. Water, 90.65 21.66 Ash, 1.36 20.46 NaCl (salt), .15 5.47 P■O■ (phosphoric acid), .36 4.55 Fat, .19 .50 Acid (as lactic), .15 8.42 Nitrogen (total), 1.15 7.66 „ insoluble and coagulable, .68 .48 „ as proteoses, .04 2.02 „ as peptones, .14 1.90 „ meat bases, .30 3.05 „ creatin, .75 „ xanthin bases, .04 „ ammonia, .21

The above analyses show the general character of meat juice extracted first by externally heating the meat and then pressing. They show that there is less nitrogenous bodies present in meat juice than there is in meat extracts. It is evident that meat extracts

cannot be heated for sterilization without coagulation of the globulins. When it is advisable to use a beef juice in a case of illness it is far better to prepare it at the time when it is used than to prepare it on a commercial scale and preserve it by any of the chemical means in vogue. Meat juice can be very well prepared for domestic use by chopping the meat very fine, placing it in a vessel, heating to 140° F., and pressing it by any simple means, as, for instance, with the hand or by using an ordinary lemon squeezer. The juice obtained in this way can be flavored with salt and spices to suit the taste of the patient, and used immediately. In some cases, in order to get a greater yield, pure cold water may be mixed with the chopped meat and a somewhat dilute juice obtained but giving a greater yield of nutritive material for the same weight of meat.

Various names, fanciful and otherwise, are given to the so-called beef juices. These names are either fanciful or, as in the case of beef extracts, that of the manufacturer. Some of the fanciful names are, like those already mentioned, suggestive of origin. Some of these have large quantities of coagulable protein, like albumin, while others have such small quantities as to indicate that they are not wholly beef juice. In the case of some of these preparations there is some indication that they are prepared chiefly from blood and thus are not true meat juices. Naturally there must be particles of blood in a meat juice and the mere occurrence of blood cells would not be an indication that blood itself had been used in its preparation. By reason of these facts the use of so-called meat juices is restricted. They contain relatively very little nutritive material, they are sometimes preserved with harmful chemicals and they may be made from blood, and in general there is such a degree of secrecy attending their preparation as to warrant the physician and patient to confine themselves to the domestic article prepared at the time of using. Another objection which is not of a hygienic character is found in the great expense of securing a very little nourishment by this means. The quantity of juice which meat will yield is very small and, therefore, the relative expense for any given quantity of nourishment is far greater than it is even in the case of beef extract. While in the case of rich patients an objection like this is of little value, in the great majority of cases it should be given due consideration.

=Soluble Meats.=--Various attempts have been made to put soluble meats upon the market for use, especially for invalids and in cases of disordered digestion. The principle which underlies the preparation of these meats is to subject them to a certain degree of artificial digestion, by means of which the protein matter becomes converted into soluble forms, either albumose, proteose or peptone. The process which is employed is a simple one, namely, the comminution of the meat into as fine particles as possible and its admixture with hydrochloric acid and pepsin. It is then subjected to artificial digestion until a considerable portion of the meat is soluble. Another method of preparation is to omit the pepsin and after the addition of hydrochloric acid to place the meat in a digestor where it is subjected to a temperature of steam under pressure for a considerable length of time. A goodly proportion of the meat becomes soluble under this process. After the preparation is completed the residual hydrochloric acid is neutralized by carbonate of soda, forming common salt, which gives the proper flavor to the compound.

The composition of soluble meat prepared in this way is given in the following table (Foods and Principles of Dietetics, by Robert Hutchinson):

Water, 67.21 percent Fat, 5.93 „ Albumin, 11.00 „ Peptone, 6.51 „ Meat extract, 7.55 „ Ash and salt, 1.74 „

A meat solution of this kind is not really a solution, since not only is that part which passes into solution contained in it, but also the residual meat fibers which are not dissolved but so softened by the process that they lose their distinct form and can be rubbed up to a thick pasty mass. The product, therefore, consists not only of the part of the meat rendered thoroughly soluble in water by the process, but also of a residual part, softened and reduced to a paste. The mass has practically the same nutritive value as an equivalent amount of meat with the claimed advantage that a large portion of it is already soluble. This partial predigestion may be of value in cases of disease or disordered digestion of any kind, but there is no reason for believing that the healthy stomach requires any sort of artificial predigestion for the proper conduct of its functions. On the other hand, there is every reason for supposing that any kind of predigestion which is at all effective will in the end prove injurious to healthy digestive organs by depriving them of a part of their normal functions and thus tending to bring them to a condition of feebleness which may result in the omission, in part, of the normal functions of the vital organs.

=Preparations of Blood.=--There is no doubt of the valuable nutritive properties of blood and its preparations are sometimes used as foods. There is a deep-seated prejudice against the use of blood as human food, doubtless based on older and more effective grounds than even the laws of health promulgated by Moses. Man is an animal of some refinement of character and the sight or use of blood is repugnant to his finer instincts. Sometimes blood is dried and powdered and the blood powder mixed with other food. Another method is to coagulate the blood, then remove the coagulated portion and use the residue for food purposes. This preparation, of course, contains no coagulable portions of blood, that is, the protein thereof known as fibrin. There is no reason for

believing that preparations of blood will ever occupy any prominent position in the food supply, either of persons in health or of invalids.

=Beef Tea.=--A very common food preparation from beef is that known as beef tea. In all essential particulars beef tea is nothing more than a rich unfiltered soup stock. Inasmuch, however, as it is constantly prescribed in many kinds of illness and is prepared under certain conditions it should be mentioned specially here in addition to the preparations already described. As in the case of meat juice, beef tea should always be prepared in the home, and immediately before using. It is a preparation which can not be properly made and kept without the addition of some preservative which renders it totally unfit for human consumption. The very choicest portion of the beef should be selected in the preparation of beef tea and it should be reduced to a fine state of comminution. The removal of the fat and tendons should be as complete as possible, as particularly the latter tend to add to the extract more of the gelatine-like principles than is desirable. The fragments should be mixed with a sufficient quantity of cold water to make the desired amount of beef tea, usually one pound of water to a pound of comminuted beef is a good proportion. The mixture should be kept cold for a considerable length of time with frequent stirrings in order to extract as much as possible of the nitrogenous matter which becomes coagulated by heating. Salt may be used not only to promote the solubility but also to give the proper taste. After the lapse of an hour or more the vessel may be covered and gradually warmed. During this warming the mass should be frequently stirred so to as promote the solution. When finally the extraction is complete, before the tea is administered it should be cooked, that is, heated to the boiling-point, by which process the soluble protein is coagulated but not hardened, and the material is rendered more palatable. The beef tea should be administered without separating the coagulated fragments of albuminous material, which is in a state easily digestible, and adds much to the nutritive value of the mixture. Finally the residue of beef may be put into a bag and subjected to pressure to remove as much of the juice contained therein as possible. The difference between beef tea and soup stock, as will be seen, is largely in the filtering. The beef tea should retain the coagulated flocks, while in the soup stock they are removed. One pound of good lean beef and one pint of water yield about one-half pound of good beef tea. As in the case of soup stock, beef tea is not a very nutritive substance. It is, however, stimulating, and the nourishment which it contains is quickly absorbed. The soft, coagulated flocks of albumin are readily digested, and often a patient may be nourished for days on a preparation of this kind when he is in a condition which renders it impracticable to use either solid or other liquid foods.

Beef tea is also made on a large commercial scale and with some degree of approximation to the home prepared article. For various reasons, however, which have already been advanced, a well made domestic beef tea which can be used as soon as prepared is to be preferred in all cases to the manufactured article. A beef tea properly made contains approximately the following composition:

Water, 88.00 percent Meat bases, 3.50 „ Protein--soluble and flocculated, 8.00 „ Ash and salt, 1.50 „

=Dried and Powdered Meats.=--The preparation of dried meat has already been described. There has lately been placed upon the market a number of preparations dried and finely ground, under various names, fanciful and those of the manufacturer. Inasmuch as ordinary meats are largely composed of water, it is evident that if the water can be removed without impairing the quality of the meat, great expense in transportation would be saved and the use of preservatives would be unnecessary. Various attempts, therefore, have been made to place dried meats upon the market. The meat powders are not only offered in their natural state of desiccation but also are prepared with a more or less previous digestion. One of the most common of these meat powders is known as somatose, which has been made in large quantities, and sold throughout all parts of the world. It consists largely of albumoses rather than of peptones, but this is true of a great many of the so-called peptone preparations. The composition of somatose is represented in the following table (Allen’s Commercial Organic Analyses, Vol. IV, page 384):

Water, 14.25 percent Albumin rendered soluble by alkali, 21.83 „ Albumin, 3.40 „ Albumoses, 33.96 „ Peptone, 3.06 „ Meat bases, 2.62 „ Ash and salt, 5.30 „

The above data show that the meat still contains nearly 15 percent of moisture and that an alkali has been used to render the protein more soluble. This alkali has increased the quantity of mineral matter over that which would naturally be present. Whatever may be the relative value of the prepared protein matter as compared with that in the original meat, it is seen that a large quantity of it, practically as much as was in the original meat, has been preserved in the finished product. Whether or not it is advisable to use a preparation of this kind is a question to be left with the physician. It may be said unhesitatingly that in all cases of health somatose could not possibly present any advantage over fresh meat. On the contrary, for theoretical and practical reasons, it is certain that it is less valuable.

=Composition of the Ash of Meat Juice and Meat Broth.=--The principal mineral component of the natural juice of meat broth or meat extract is phosphate of potassium, though there are also small quantities of magnesium and smaller quantities of calcium present. In addition to this there is a certain quantity of common salt present, which is determined, however, largely by the method of preparation. The following analysis shows the composition of the ash of a meat juice to which little or no common salt has been added:

Potassium (K), 34.40 percent Sodium (Na), 9.70 „ Calcium (Ca), .36 „ Magnesium (Mg), 2.55 „ Phosphoric acid (P■O■), 27.00 „

Other constituents are not determined in this analysis. The phosphate of potassium may therefore be regarded as the principal natural ash constituent of meat extract and meat juice. (Zeitschrift für Biologie, Vol. XII, 1876.)

=Adulteration of Meat Extract.=--The principal adulterations of meat extract have already been mentioned. The substances used in preserving it are of the greatest hygienic consequence. These are chiefly salt and glycerol or alcohol. The use of all of these substances is reprehensible. Fortunately they are seldom used. Another adulteration which has been practiced is mixing the meat extract with extracts of yeast. The extract of yeast has valuable dietetic properties and contains the active principles of fermentation. It also resembles, in many respects, physically and chemically, the extract of meat, and can, therefore, be mixed with meat extract, and, being a cheaper article, forms a mixture which can be sold at a greater profit. The presence of yeast extract in meat extract can easily be determined by treating the mixture with a strong solution of sulfate of zinc and filtering. In meat extract the filtrate obtained is always quite clear, but when a yeast extract is present the filtrate is turbid.

=Active Principles Contained in Meat Extract.=--Attention has already been called to some of the more important active principles, namely, meat bases which form a valuable portion of meat extract. There are various forms of nitrogenous bodies, however, besides meat bases, which become soluble naturally in meat or by the treatment of meat with digestive ferments. Lean meat, as is well known, consists almost exclusively of protein matter and water. This protein matter is principally insoluble. Under the action of digestive ferments the protein of meat becomes broken up into more soluble bodies, known as albumoses, proteoses and peptones,--the latter being the final product of solution. These bodies are still true protein bodies containing the elements of sulfur as one of their essential constituents. The meat bases, on the contrary, contain the other elements that are in protein but do not have the sulfur element. They belong to that class of bodies which is known as simple amido compounds. All of these bodies are mixed together in meat juice or beef extract, and it is an important task of the chemist to separate them, both from an analytical point of view and the determination of their relative abundance. There is also another soluble or semisoluble protein substance in these extracts derived from the tendinous tissues and bones, namely, the gelatine or glue. This is quite a common product, being the soluble protein procured by the digestion of the tendons and bones. It is important, therefore, that the chemist should distinguish between the gelatine and the amido bodies. There is also a true and a false protein form of these soluble bodies, the true one being formed by natural proteolytic ferments and the false one being formed by heat or digestion under pressure of steam. The chemist should also be able to distinguish between the true extract formed directly from the meat and the yeast extract used as an adulteration.

It is not the purpose of this manual to enter into the details of how these different bodies may be distinguished from one another, as that is purely a chemical study. It is due, however, to the general reader that some explanation be given of the different classes of bodies which are contained in these extracts.

=Relation between the Price of an Extract and its Nutritive Value.=--The studies made in the Bureau of Chemistry show that there is little relation between the price of a beef extract and its real nutritive value. In three cases of extract which are all well known brands and are of the thick or pasty variety, showing that a dissolved meat had been added to them, the average weight of a package costing 45 cents was only 55 grams, or nearly a cent a gram. In another three samples of extract, also well known brands, of the same pasty variety and costing little more per package, it was found that the weight of the more expensive variety was double that of the first, costing only one-half cent per gram. In the case of the liquid extracts where no pasty material is incorporated there is still greater variation in the relation of the price to the nutritive constituents. An extract which retails for one dollar per bottle contains 91.69 percent of water and only .42 percent of nitrogen. Another so-called meat extract which retails at 60 cents per bottle must have been wholly an artificial product, since it contained no creatin or creatinin at all. It was also preserved by the addition of alcohol and contained an artificial coloring matter.

The ash existing in these extracts is, of course, usually due to the presence of large quantities of common salt. Sodium chlorid is added to this extract without any definite rule at all and sometimes in very excessive quantities. In some cases thirty percent of the

total extract is composed of common salt. In other words, a person taking a solution of this kind would be injecting into his stomach a very concentrated brine. When common salt may be sold at the rate of one dollar per pound, the profit on the transaction is one which ought to make the business exceedingly attractive.

The total phosphoric acid in the ash also shows variations, and if it were not so easy to add artificial phosphoric acid the actual amount present might be taken as a base by which quality could be judged. In the natural extract the total phosphoric acid should be in the proportion to organic phosphoric acid as 10 to 1, which is the natural condition in which it is found in meat extract. In many cases the amount of inorganic phosphorus is so great as to render it certain that a phosphate, probably the phosphate of soda, has been added. In another case the quantity of organic phosphoric acid was very much greater than could have possibly been the case in a natural product, indicating the addition of lecithin or glycerophosphoric acid. The amount of fat in beef extract, when properly prepared, should be very small and should certainly not exceed one percent, since by the proper method of preparation the fat is largely separated. In the pasty material, however, where the meat is reduced to a pulp and retained in the package the amount of fat will be very much greater.

=The Nitrogenous Bases.=--The average nitrogen content of the pasty or solid extracts varies from 6 to 9 percent. The nitrogen in the meat juice is subject to much greater fluctuation, depending largely on the content of solids. Although a high nitrogen content is not a guarantee of the character or mode of manufacture of an extract, it is naturally expected and is desirable.

The addition of gelatine to extracts is now largely practiced and has been for some years. By adding gelatine the manufacturer raises or maintains a certain nitrogen content, but supplies the nitrogen in a form lacking in all quickly stimulating qualities, and the natural flavor of the meat extract nitrogen is lowered. The buyer is consequently deprived of the characteristic essentials of a beef extract although the nitrogen content is relatively high. In many cases only a small proportion of the original gelatine exists in the extract as such. The gelatine is converted by a gradual process of hydration into gelatoses and gelatine peptones. While the separation of gelatine from protein matter is a process in anything but a satisfactory condition, it is a far simpler process than the detection and separation of gelatoses and gelatine peptones from albuminoses and peptones. The question has not been thoroughly studied up to date.

The question of adulteration of meat extracts with gelatine is not the only form of adulteration we have to face. The mixing of varying amounts of yeast extract with meat extracts is being practiced at the present time in some countries. As we have not investigated this question, we cannot state whether it is practiced in this country at the present time or not.

=Kinds of Preparations.=--Meat preparations of the above types in general may be divided into three classes, liquid extracts, pasty extracts and powdered extracts. In addition to the above, within the last few years beef extract pellets, some of them being enclosed in gelatine capsules, have appeared upon the market. The old-time product of Liebig’s extract belongs to the second class, in which we also find many of our best known brands. The liquid extracts are varied and numerous and their number is rapidly increasing. The amount of meat extractives in some of these liquid products is remarkably small, the quantity of solids in two or three cases being under 10 percent. Alcohol is sometimes met with in these liquid preparations. The meat powders are far less numerous than the extracts of the first two classes. They consist largely, if not entirely, of albuminoses and peptones in addition to some insoluble proteid matter.

Moreover, it is necessary to distinguish between a meat extract containing large amounts of stimulating amido-acids and relatively small percentages of albuminoses, peptones and insoluble proteid matter on the one hand, and, on the other hand, an extract, or, more properly, a meat product, which consists largely of albuminoses, peptones and insoluble matter and relatively small amounts of amido-acids. The food value of this last group of products is undoubtedly greater than that of the former group, but being sold as meat extracts, their value should be based on the amount of extractives they contain and not on their food value.

The value of the amido-bodies, such as the meat bases, as food, is of uncertain character, but we must admit, as in the case of alcohol, they can at least be burned and furnish energy to the body. Like alcohol, the value of meat extractives lies principally in their stimulating qualities. The active principles of tea and coffee are on a similar basis. As these simpler amido-bodies are the final links in the long chain of hydrolytic products of the proteid molecule prior to the complete resolution of that molecule into carbon dioxid, water, etc., it is readily seen that an ounce of meat extractives (the various amido-bodies) represents a far larger amount of beef than an ounce of albuminoses does. The various protein bodies and amido-acids are closely interwoven and it is impossible to produce amido-acids without producing albuminoses and peptones. Consequently, every commercial meat extract must consist partly of albuminoses, peptones, etc. The best of our extracts on the market to-day contain about 50 percent of their total nitrogen

in the form of meat base nitrogen. When an extract contains less than 5 percent of its nitrogen in the form of meat base nitrogen the term “extract” seems to be no longer applicable. It is evident that the product represents much less meat than an extract with 50 percent of its nitrogen in the form of meat base nitrogen, provided the total nitrogen in both cases is approximately equal.

The proteid matter coagulated by heating to boiling, as well as the proteid matter insoluble in cold water, are both undesirable factors in an extract of meat. As a rule, the lower the proportion of these constituents, the higher the character of the meat extract. The same thing holds true in regard to the presence of albuminoses and peptones.

The quantity of total nitrogen in the form of meat base nitrogen in the best extracts reaches 50 percent. In one of the poorest it is 3.82 percent. The food value of the latter product might be greater than that of the former, but its cost of manufacture and its stimulating value are much less.

Creatin figures are very interesting and of much value in determining the source and value of an extract. Creatin is the principal amido-body found in meat, consequently we expect to find it or creatinin, its hydrated form, in still larger quantities in meat extracts. In several cases which came under our notice where the extract acted suspiciously, the creatin values were nil, and in such cases grave doubts exist as to the source of the extract. Our best extracts give high creatin as well as high meat base figures.

The xanthin bases and ammonia nitrogen figures present a variety of problems. While the xanthin bases are desirable constituents, ammonia in any amount is not. It is questionable whether the ammonia figures obtained by the magnesium oxid method do not give too high results (W. D. Bigelow).

=Gelatine.=--Gelatine is a substance obtained from the nitrogenous portions of bones, hide, horns, hoofs, connective tissue, tendons and other nitrogenous matter of the animal. One of the principal constituents of these bodies is a substance known as collagen. When this is heated either under pressure or without pressure it is changed to gelatine. Glue is unrefined gelatine or impure gelatine to which usually some substance has been added to increase its holding power. A type of gelatine known as isinglass is made from the bladders of sturgeons.

The general process of manufacturing gelatine is as follows (Whipple, Technology Quarterly, Vol. XV, No. 2, June, 1902):

“The hide scraps are first macerated and subjected to the action of a solution of lime or caustic soda in pits for two or three weeks. This dissolves most of the blood and saponifies the fats. The excess of lime or soda is then largely removed by washing and the solution steamed to dissolve the gelatine, but an excess of heat is avoided. Sulfurous acid is used to bleach the gelatine. When of sufficient strength, the gelatine is allowed to harden in molds or on slabs, and is ultimately dried in sheets on wire nets. Bone gelatine is made in a somewhat similar manner. The bones are crushed, boiled, treated with hydrochloric acid, and the gelatine is dissolved as before, washed, bleached and dried in sheets. The process requires a number of weeks.”

Gelatine is also made from bones, fresh as well as old, and from the residues of bones used in the manufacture of buttons. The thin slices of the bones are treated with acid until all the phosphate of lime is extracted. They are then treated with lime and the gelatinous residue is then dissolved in warm water and purified for use.

The use of gelatine as a food has of late years become very common. The ease with which it can be made into jellies, the consistence which it gives to ice-cream and its general utility in the cuisine have made it deservedly popular. Gelatine is the product of some of the nitrogenous parts of the animal and should be made only from the edible parts thereof. It is particularly abundant in the tendinous portions of the animal and in the tissues about the head, from which a large part of edible gelatine is made. No portion of the animal which is filthy or unfit for food should ever enter into the composition of the gelatine. If the parts from which the gelatine are made are cured previous to manufacture they should be cured in a perfectly sanitary way, as carefully as any other part of the meat. There can be no objection to the use of gelatine made from these sanitary materials in foods of all kinds.

There is, however, a possibility that some of the gelatines on the market may be made from materials wholly unfit for food. The food law forbids the use of animal substances unfit for food either directly or indirectly. As an illustration of this condition of affairs I may call attention to the fact that a part of the gelatines sold in the United States are made from parts of animals slaughtered in South America. It is not known to the consumer in what conditions these parts are preserved and transported. They may be possibly packed with the hide and sent to Belgium or other countries in a filthy, putrid and abhorrent state and these parts be cut from the hides before they are sent to the tanneries and converted into gelatine and sold as edible gelatine. Such a possibility should not exist, and there is no danger of its existence with high class manufacturers. A part of the horns is also used for such purposes, which being of an inedible portion and unfit for food is not admissible, under the law, as a constituent of edible gelatine. All such

materials should be excluded in the manufacture of such an important product. Further than this, it may be stated that the line of demarcation between gelatine and glue is not always as well drawn as it should be, and this is illustrated in the report that the gelatine and glue are manufactured in the same factory, and the same conditions of odor and insanitation which adhere to glue may attach themselves to the gelatine. Such a condition, of course, would be an exceptional case, but its possibility should be excluded. Under the food law only those forms of gelatine first described above can be legally made and sold for use in food.

Adulteration of Gelatine.--The adulterations of gelatine are such as those referred to above in the form of raw materials employed which are insanitary and unfit for food. In addition to this, bleaching agents, namely, sulfurous acid or sulfites and mineral acids, are often employed in the manufacture, portions of which may remain in the finished article. All of these substances must be regarded as adulterants and as insanitary and unsuitable to gelatine, and to that extent unfit for human consumption.

Presence of Tetanus in Commercial Gelatine.--The Public Health and Marine Hospital Service has investigated gelatine to determine whether or not it may be infected with pathogenic germs. The conclusions of the investigation are as follows (Bulletin No. 9, Hygienic Laboratory):

“Seven samples of gelatine examined; one showed tetanus spores.

“Two samples showed an oval end-spore rod, whose identity was not proved, but, in stained specimens, it would be hard to distinguish from tetanus, if indeed not tetanus with diminished virulence.

“In tetanus investigations it is important to use _freshly_ made bouillon, as the organism is apt not to germinate in bouillon over ten days old. The thermal death point of the organism isolated was found to be between twenty and thirty seconds at 100 degrees C.

“It is important, therefore, that gelatine to be used for injections should be boiled at least ten minutes on account of the variability of the thermal death point in different species of tetanus. Whether this amount of heating impairs in any way the hemostatic power of gelatine has not been settled, but in case it does it is believed that the danger from tetanus more than overbalances its therapeutic value.

“It is suggested that when, as in hospitals, there is likelihood of gelatine injections being used for hemostatic purposes the gelatine solution be sterilized by the fractional method on three successive days and kept ready for use in sterile containers.”

From the data given above it is seen that gelatine may become infected and the material from which it is made for edible purposes should be healthful, sanitary and fit for food. It is not likely that tetanus germs would prove dangerous when taken into the stomach, but freedom from infection should be secured if possible. These investigations show the wisdom of the pure food law in forbidding the use of parts of animals unfit for food, whether manufactured or not, in the production of food products. It is evident that a sufficient quantity of fresh, sanitary material or material properly preserved can be obtained in this country or in other countries to supply the needs for edible gelatine without resorting to the use of inedible parts of hides, horns, hoofs and other waste and unfit portions of the animal.

=Summary.=--Above have been presented some of the principal meat foods, the analytical data which show their composition, the processes by means of which they are prepared and the principal methods, objectionable and otherwise, by which they are preserved.

Meat is a staple article of diet among almost all nations of men. The anatomical structure of the human animal indicates that his environment has adapted him to eating meats of all kinds. In other words, man is an omnivorous animal. He has been developed in an environment in which all kinds of meats and vegetables have ministered to his sustenance, and thus he is an omnivorous animal both by evolution and necessarily by heredity. That man can live and flourish without meat has been fully established by experiments, but that man cannot be nourished by meat alone has likewise been fully established, so that if the human race were necessarily to be deprived either of animal or vegetable foods, it would be the animal food which must be sacrificed.

It is not the purpose of this manual to discuss the relative merits of vegetarianism as compared with the common diet of the human race. It may not be amiss, however, to say that probably in the United States especially, a larger quantity of meat is eaten than is either necessary or wholesome. The people of our country are better able to supply themselves with expensive foods than those of other countries, and of the common foods meats are far more expensive than cereals. The eating of larger quantities of cereals and smaller quantities of meat would probably be conducive both to economy and health. It appears to be certain that the meat eating of the future may not be regarded so much as a necessity as it has in the past, but that meats will be used more as condimental

substances than as staple foods. In all meat, for instance, that costs 25 cents a pound, such as steaks, there is over one-third or a half of it which is inedible, so that the edible portion really costs double that amount. On the contrary, when a pound of flour or maize is purchased, the price of which is perhaps only one-eighth that of meat, the whole of it is edible. Thus, from the mere point of economy as well as of nutrition the superiority of cereals and other vegetable products is at once evident. On the one hand, a cereal is almost a complete food containing all the elements necessary to nutrition, and it costs only a few cents a pound. On the other hand, a steak or roast is only a partial food and it costs much more than cereals.

It is hoped that one purpose of this manual may be secured, namely, by showing the consumer the actual composition of the different kinds of food and their method of preparation he may be led in the selection of his food to follow the dictates of science and economy to a certain extent rather than merely the impulse of taste. The eating of such large quantities of meat is merely a habit which often is developed in children through the carelessness and ignorance of parents, much to the detriment of the child as well as to his future health and activity. It is believed that if the true principles of the use of meat were properly inculcated a large saving in the energy of the wage earner as well as those in more affluent circumstances would be secured.

Sound principles of economy establish a better condition of health and lead to greater activity and fruitful labor.

TERRESTRIAL ANIMAL OILS.

Terrestrial animal oils are obtained directly from parts of the animals which yield, at ordinary temperature, a substance which remains liquid. The fats which are in the feet of the animals are usually more liquid than in any other part of the body, and hence the natural animal oils are derived largely from the feet. Among the most important are sheep’s foot oil, horse foot oil, and neat’s foot oil, which is obtained from the feet of cattle. These oils are all highly valued for technical purposes, especially for lubricating, and for this purpose bring a very high price. They are not used or should not be used for edible purposes, though they perhaps may sometimes be used in cooking. Neat’s foot oil, especially, on account of its high price, is often subjected to adulteration, and is mixed for this purpose with cheap vegetable oils, such as cottonseed. Fish oil is also often used in the adulteration of neat’s foot oil, though the addition of any of these oils to neat’s foot oil raises the iodin number to a very high degree, and hence this addition is easily detected by the chemist.

=Lard Oil.=--Lard oil is one of the most important of terrestrial animal oils. It is made from lard by melting it and allowing it to slowly cool. The stearin in the product crystallizes first, and when it reaches a condition favoring the separation of the stearin the mass is subjected to straining or pressure, whereby the olein or liquid portion of the oil is separated, and thus, having been freed from the most of its stearin, remains liquid at ordinary temperature. The residue is known as lard stearin and is largely employed in the preparation of lard to give it a higher melting point and in the manufacture of oleomargarine.

Lard oil is used to some extent for edible purposes and is itself sometimes employed in the manufacture of oleomargarine when mixed with tallow or tallow stearin.

Properties of Lard Oil.--It is evident that the chemical and physical properties of lard oil are determined by the completeness with which the stearin is separated. Inasmuch, however, as the conditions of manufacture are nearly constant, lard oil has characteristics of a physical and chemical nature which do not vary greatly. The specific gravity of lard oil at 15 degrees is about .916, and its iodin number varies from 68 to 75. When made of the best material it has a neutral taste, not an unpleasant odor, and, therefore, can be used for edible purposes without introducing any characteristic odor or flavor into the prepared food. In point of fact, however, it is not used to any extent for edible purposes except in the manufactured articles above mentioned. When carefully made and of the proper quality pure lard oil should be practically free from free acid.

Adulterations.--On account of the high value of lard oil for lubricating and other purposes it has been subjected to extensive adulterations. The addition of cheaper animal oils or vegetable oils has been largely practiced. Fish oil, blubber oil, and other marine animal oils have also been freely used in the adulteration of lard oil whenever the difference in price has rendered it advisable. These adulterations are of such a character that they can be detected only by the skilled microscopist and chemist. The other animal oils, both of marine and terrestrial origin, while important from a technical point of view, are of no significance in respect of edible qualities.

PART II.

POULTRY AND GAME BIRDS.

=Application of Name.=--The term poultry for descriptive purposes may be applied to those classes of feathered domesticated birds used for human food. It, therefore, includes practically all of the domesticated fowls. The term game bird, for the purpose of this manual, is applied to feathered animals which are wild and which are used for human food. This also may apply to almost all wild birds, since at times they practically all have been used for food purposes. Here only those in common use, both domesticated and wild, will be referred to. In connection with poultry the eggs of the birds will be considered.

DOMESTICATED FOWLS.

The principal domesticated fowls which are used for human food are chickens, turkeys, geese, ducks, and guinea hens. The most common of all is the chicken,--the next perhaps are turkeys in this country and the goose in Europe. The others are more infrequently used but are highly prized.

=Chicken.=--The chicken scientifically is known as _Gallus domesticus_. For food purposes the chicken is eaten at various ages. The very young chicken is commonly called a broiler and is prepared for the table at varying ages from six to twelve weeks. Young chickens are also very commonly called spring chickens, since they occur in greater abundance in the spring than at any other time. Since the introduction of the modern method of incubation, however, the spring chicken may be had at all seasons of the year. The “broiler” and “spring chicken” may be regarded as synonymous terms, though the larger chicks are usually called spring chickens instead of broilers.

Full Grown Chickens.--The full grown chicken is better suited for food when still young. The flesh loses flavor and gains in toughness as the chicken grows older. There is no legal limit fixing the division of chickens into different classes with respect to age and the only criterion is the price and taste of the consumer. There is, perhaps, no objection to the use of old chickens for food purposes, provided they are not sold fraudulently as young chicks. The size and toughness of the pieces one often secures when ordering spring chicken is an indication that the age limit is not very definitely established. Both hens and roosters are used for food purposes, but especially the young roosters are devoted to food purposes while the young hens are often kept for the production of eggs.

Preparation of Chickens for Food Purposes.--In former times, when the chickens of commerce were derived chiefly from the farm, no special preparation was made before the chicken was marketed. The eggs were hatched in the old-fashioned way by the hens and the chicks sold to hucksters or in market, at various ages and without any special preparation or control. All this has been changed in later times by the introduction of scientific methods of breeding poultry. It has been demonstrated that the breeding and care of poultry require as much scientific and economic attention as is devoted to any other successful business.

[Illustration: FIG. 12.--CHICKEN HOUSE, RHODE ISLAND EXPERIMENT STATION.]

The Incubator.--The introduction of the incubator for the hatching of eggs with the other necessary arrangements for the caring for young chicks has perhaps done more than any other one thing to revolutionize the method of preparing poultry for the market. By the use of the incubator the hatching of chicks is regulated with the utmost degree of nicety. A larger percentage of eggs produce chicks and the expense of the incubating process is greatly diminished. The incubator is in its widest significance a thermostat in which the eggs may be placed and maintained constantly at the temperature of the hen’s body, namely, about 102 degrees F. The arrangement of the chicken house and the other environments of the young chick are shown in Fig. 12.

Care of Young Chicks.--The principal points in the care of young chicks are fresh air, freedom from infection by epidemic or contagious diseases, exclusion of insect pests, even high temperature, and abundance of food. The young chick is especially sensitive to low temperatures and must be protected from cold, especially from cold rains. For this reason the chicks, after hatching, must be kept, if it is not summer time, in a room where the temperature can be regulated until they have acquired some degree of strength and vitality. The temperature of the chicken house for the young birds should not be lower than 85 or 90 degrees F.

A temperature of about 102 degrees F. is found very favorable to the development of the chicks in the eggs, although the temperature may sometimes fall to 101 or rise to 103 degrees F. without materially affecting the results. Experiments show that too low a temperature arrests the development of the chick. On the contrary there seems to be no indication that an increase of heat,

up to 103 degrees F., has any tendency to kill the chick in the last stages of development. It is found best in all cases to set the eggs in the incubator as soon after they are laid as possible. Where the age of the egg is not known it should be carefully candled, that is, held up between the eye and a light in order to determine its condition. In old eggs, the yolk, on candling, becomes more or less diffused with the white and such eggs are to be rejected for incubator purposes as they are not likely to produce chickens. The fertility of the egg must also be assured before placing in the incubator. An unfertilized egg is so much loss in the incubator since it might have been used for food purposes, since the egg, for marketable purposes, when fresh is just as good as a fertilized egg. It is an observed fact that the complete fertilization of the egg, that is, the proper union of the male and female germ cells, is not always complete at the time the egg is laid, but the mingling of the two elements takes place under proper conditions afterwards. The development will also depend upon the vitality of the germ and its component parts. Just, for instance, as the color of the feathers, the size of the body and the general character of the chick may be inherited from either parent, so the vital qualities are much more strongly shown in some eggs than in others. The proper germination of the egg may also be improved by many of the conditions of environment. In the case of eggs, any slight change which would interfere with the functions of the yolk or albumin, both of which are extremely sensitive to change, would interfere with the growth of the embryo either by depriving it of food or subjecting it to other conditions in which its vitality would be diminished or destroyed. The fertilized egg may be separated from the non-fertilized also by candling. At the Rhode Island station it is found that a very good light for candling is the ordinary calcium carbide bicycle lamp, placed in a proper candling box. This is a strong white light quite equal in power to the electric incandescent light and is not so trying to the eyes.

When eggs which have been submitted to incubation permit light to shine through and show the yolk suspended in the upper half of the center as a clearly defined mass, which quickly reassumes its position in turning the egg with its long axis nearly horizontal, they are probably infertile or sterile. When, on the contrary, the yolk assumes indefinite outlines, approaching near the upper portion of the shell at the large end or appears with a thick spur upon its upper side, it may be regarded as having started to incubate. In the later stages the embryo can be plainly seen, because it becomes opaque and cuts off more of the light. In the incubation of eggs the candling is resorted to during the first few days of the experiment in order that the unfertilized eggs may be separated. The best time for the candling, if it is practiced only once, is on the sixth or seventh day of incubation. By that time all the eggs which are fertilized will be so changed as to be easily recognized by the candling process. Experience has shown that eggs which are more than two weeks old are not profitable for use in incubators since the percentage that does not hatch is so large. The incubating part of the plant is sometimes placed in the cellar over which the brooding house is built.

The brooding of young chicks is of the utmost significance. In Europe the changes in temperature are much less violent than in this country. The principal brooding houses in the United States are in the North where the temperature often falls in winter to below zero while in the summer it may rise to blood heat, a difference of over 100 degrees F. For this reason the incubating houses in the United States are often placed in cellars where the uniform conditions of temperature are more easily secured. There is no objection to this location provided proper care be taken to secure ventilation and the proper content of moisture in the atmosphere. In Great Britain the incubating houses are usually placed above ground instead of in cellars. The mean range of temperature in an incubating room in Great Britain, from March 12, 1903, to March 30, 1904, was 10 degrees. The highest temperature registered was 70 degrees on the 24th of June and the lowest 42 degrees in January. The humidity of the air was also quite constant, the lowest degree of humidity being 59 and the highest 94. These data show a very even temperature in the room itself. Of course the temperature in the incubator is necessarily greater, being that already referred to, namely 102 degrees.

Early Market.--One principal object in the raising of chicks is to force them to an early maturity in so far as size and palatability are concerned. The sooner the young broilers can be made ready for the market the more economy there is in their production. To this end they ought to receive a more abundant and specially prepared kind of food than if they were intended for ordinary farm purposes. In other words, the forcing process should be pushed as far as possible without interfering with the health and normal functions of the bird. Foods which are nutritious and stimulating and promote vigorous growth should be employed. Birds prepared in this way for the market are extremely tender and palatable and bring the highest prices where their merits are recognized.

Artificial Feeding.--Where chickens of greater age are prepared for the market they are subjected, during the last two or three weeks previous to sale, to a forcing process in order to produce more fat and make their flesh more palatable. To this end the chickens are fed from time to time mechanically by passing a tube into the craw and forcing the food therein. Fowls prepared in this way bring high prices in the market and the largest profits to the growers. It is a method, however, which is not used in the raising of the ordinary poultry found on the market.

Preparing Chickens for the Market.--Chickens are sold in four different conditions in the markets of this country. First, they are offered alive. A great many purchasers prefer to get their poultry in this way because they can then be certain that it has not been long killed and kept in cold storage or preserved by means of chemicals. It is a very common custom for consumers to have their own chicken coups and buy a number of birds at a time and fatten them particularly for their own use. Under the present system of law this method is highly to be commended as a certain way of knowing the age of the poultry consumed. With proper municipal and state regulations of the markets it would not be necessary for the consumer to go to this trouble since when rigid inspection and certification are established, the age of the chicken offered on the market can be easily ascertained. Until such time comes, however, on the part of the consumer, the desirability of securing chickens alive cannot be denied.

Freshly Killed Chickens.--Chickens which have been killed within twenty-four or forty-eight hours and properly kept may be regarded as freshly killed. There is a very wide-spread opinion, and probably founded on reliable experiments, that fowls are better if they are kept some time after slaughter, provided they are kept in a proper way. In the winter time it is customary, especially in Europe, to hang the fowl for a week or ten days exposed to the ordinary temperature, before consumption. This, of course, is a practice which could not be indulged in in warm weather. Fowls, however, can be hung in cold storage even in the summer time and with the same advantage which accrues by hanging them in ordinary temperature in the winter time. Just how long fowls should be kept after slaughter in this way in order to secure a maximum degree of palatability has not been scientifically determined. There is evidently a limit beyond which the keeping of slaughtered fowls should not be indulged in. If a low and even temperature could be secured it may be certain that the hanging of the fowl for a week or ten days is not too long. The temperature, however, should not be much above the freezing point.

Freshly killed chickens are offered in two forms, namely, drawn and undrawn. The proper method of keeping a slaughtered chicken has been the subject of very lively discussions. There are many who are advocates of the exposure of the chicken in the undrawn state asserting that in this condition it is less exposed to infection and keeps better during the necessary time elapsing between slaughter and consumption. This argument is advanced chiefly by dealers. On the other hand the consumer, as a rule, is in favor of having the chicken drawn before it is exposed for sale, that is, as soon as it is slaughtered. There is perhaps much to be said on both sides of this question. If, however, chickens are to be secured by the consumer within forty-eight hours after slaughter there can be no very great danger of infection by having them undrawn. The subject is one of sufficient importance to warrant an extended scientific investigation and upon this investigation the municipal and state regulations for the sale of poultry can be based. It is not wise in such cases to be swayed solely by prejudice or sentiment but rather by the facts which can be ascertained by unbiased scientific investigation. Because a chicken weighs more undrawn is probably one of the reasons why dealers prefer them in this state. It may be said, too, that the intestinal organs are so impenetrable to the diffusion of their contents as not to create any danger of contamination by remaining in the undrawn state. On the contrary, the keeping of chickens with the intestinal contents undisturbed does not appeal to the imagination of the consumer any more than the freezing of the carcass of a beef or hog with the viscera remaining would appeal to the consumer. If the carcass of a chicken can be better kept undrawn it is evident that the carcass of a steer or hog can also be better kept if subjected to the proper temperature. Upon the whole it appears that the safer way would be to have the poultry drawn at the time of slaughter and delivered to the consumer at an early date thereafter. In this way all danger of infection on the cut surfaces becomes avoided. At any rate the consumer should be allowed the choice in the matter which, at the present time, is not the case in many parts of this country where only undrawn poultry is exposed for sale.

Poultry in Cold Storage.--Whenever a fowl is kept for a longer period than the week or ten days above referred to for the purpose of improving its flavor and palatability it is necessary that it be placed in cold storage. This method of keeping poultry or other foods is wholly unobjectionable unless carried to excess. Poultry is a food product which under the present scientific methods of production can be furnished in a fresh state all the year. The necessity for cold storage, therefore, is not so apparent in this case as in that of fruit and other perishable foods. It appears then that cold storage only should be extended to that limit necessary to secure its delivery to the consumer. There can scarcely be any excuse for the placing of poultry in cold storage at certain seasons of the year when they are slightly less in price by reason of the abundant production than at other seasons. The methods of producing poultry are such at the present time that this excess in supply can easily be avoided on the part of the producer and thus maintain an even price and an even supply the year round. The producer as well as the consumer is benefited by such a condition. The necessity, often, for cold storage in the limited sense above referred to is acknowledged by all and a reasonable degree of time in cold storage cannot be regarded as in any way measurably harmful with reference to the character of the product. It is probable that as long as four or six months may be regarded as a justifiable limit for securing a proper market for poultry in cold storage though the exact length of time in which it may be left in cold storage will be determined only by careful scientific investigation.

There seems to be no necessity whatever for carrying fowls for a longer period and especially, as has been known, for a year or even two years. The deterioration, even if the temperature is far below the freezing point, is very marked during these long periods of time and actual danger may accrue to the consumer in the possible development of poisonous degradation products in the flesh. Municipal, state, and national regulations should be of a character to inform the consumer of the exact length of time which the poultry he proposes to purchase has been in cold storage. This is the least which the consumer has the right to know and is a right which the producer and packer should concede without discussion. The unwillingness which has been manifested on the part of dealers in poultry to make public the length of time which it has been in cold storage is of itself a suspicious condition. The argument is constantly heard that the length of time poultry has been in cold storage does not impair its palatability or wholesomeness. If this be true then a statement of the length of time cannot in any way injure the market. But to this reply is made to the effect that if the consumer is told the fowl has been in cold storage a certain length of time he will not purchase it. To this the evident answer is,--why should you deceive the consumer by selling him an article which if he knew its character he would not buy? It is evident that such deception is nothing more nor less than obtaining money under false pretenses. The remedy for the evil of cold storage is the label which will indicate the length of time which has elapsed since the slaughter of the fowl.

There is, perhaps, no greater blessing which has been conferred upon mankind during the last quarter of a century than the development of cold storage methods of preserving food. The continued prosperity and benefits of this business depend upon a thorough study of the conditions attendant thereon and the elimination of any evil which may be incident thereto. When this is accomplished the absolute confidence which the consumer will have in cold storage will be such that the magnitude of the business will be immensely increased. Thus the interests of the consumer and the dealer are one and they should work together to promote their common good.

Composition of the White Meat of a Chicken.--The meat of a chicken, carefully prepared in the laboratory of the Bureau of Chemistry, was analyzed by separation into the white and dark portions. The composition of the two meats is as follows:

WATER IN FAT-FREE MEAT WATER. SUBSTANCE. FAT. PROTEIN. BASES. Percent. Percent. Percent. Percent. Percent. White meat, 61.38 75.08 18.25 17.06 .37 Dark meat, 59.48 78.44 24.16 15.94 1.03

The above data show that there is a notable difference in the composition of the white and the dark meat. The white meat has much less fat and a correspondingly larger quantity of protein. The quantity of water in the two classes of meat is not very different although there is a slightly less quantity in the dark meat. The dark meat has a much larger proportion of meat bases but as these bases are often considered of little value and sometimes degenerate into poisonous constituents it is seen from this point of view that the white meat is to be preferred to the dark meat.

Preserved Chicken.--Practically the only methods of preserving chickens are the canning processes which have already been described and cold storage. Chickens may be canned in the same way as has been described for beef and in that way may be kept for a certain length of time without notable deterioration. The pickling of chicken is not very extensively practiced nor is it cured in the ordinary sense of the word, that is, by the addition of salt, sugar, vinegar, spices, and wood smoke. Chicken may also be put up in the form of potted chicken, which has already been described. Practically the only methods which are in vogue and which can be commended for preserving chicken are sterilizing or canning and cold storage. These methods, when not unduly prolonged, are open to no reasonable objection. The preserving of chickens with spices and condiments may also, perhaps, be considered as desirable provided no harmful chemical preservatives are employed. The temptation, however, to employ such preservatives is so great as not to be always resisted.

Adulteration of Potted Chicken and Turkey.--Perhaps there is no other form of potted meat, with the possible exception of pâté de foie gras, where such an opulent field for sophistication is found as in the case of potted chicken and turkey. The average composition of ten samples of alleged potted chicken and turkey, found upon the market, is shown in the following table:

Water, 58.52 percent Water in fat-free substance, 71.24 „ Fat, 17.98 „ Protein, 19.12 „ Meat bases, .96 „ Glycogen, .26 „ Total ash, 2.67 „ Of which sodium chlorid, 1.05 „

All but one of the ten samples contained starch but not in very considerable quantities, the largest amount being 4.13 percent.

None of the samples contained saltpeter. This is an interesting point because of the claim of the packers that saltpeter is used solely for preservation purposes. When a meat is expected to be of a white color no saltpeter is found while, on the contrary, where the meat is of a red character it is frequently found. Tin was present in four samples, doubtless due to some contamination with the

solder or by corrosion of the tin can itself. Where tin is present due to the corrosion of the can itself it is always in greater abundance in the old than in the newly canned sample. It is quite certain that the contents of these packages were not made up of chicken and turkey exclusively. The characteristic odor and taste of smoked meats which are found in these packages would indicate that they are used to give flavor and aroma to the mixture. The addition of flavoring materials of this kind, or “force” meats as they are sometimes called, is not objectionable from any sanitary or dietetic point of view. It is, however, an offense against an ethical principle which must be closely followed in a case of this kind if the doors of fraud and adulteration are not to be left wide open. This principle is that no false idea by inference, omission or otherwise, should be conveyed to the consumer by the label. Some form of expression for potted meat should be used in which the label gives the principal or dominant meat in the mixture, accompanied by the statement that it is a mixture with other meats also named, spiced and flavored. Under the present condition of affairs a manufacturer who really wishes to put into potted form chicken and turkey with only spices and condiments has to undergo an unfair competition with another manufacturer who uses the same label and reduces the quantity of expensive meat to a minimum or may possibly leave it out altogether. Under the new food law this unfair competition will be prevented.

Adulteration of Chicken.--The flesh of chicken is not subjected to any very extensive adulterations. It has been claimed that preservatives are applied externally to fresh fowls but the evidence on this point is not very conclusive. There is, perhaps, little doubt that other methods have been practiced but probably without any very great vogue. The use of chemical preservatives in potted chicken is also reprehensible. In general it may be said that there is no very extensive adulteration of chicken meat. The principal objection to the commerce in preserved chicken meat is the use of old chickens, the unlimited cold storage, the failure to draw at time of slaughter, and exposure in the market in an unsanitary condition and for an indefinite time. Cheaper meats are sometimes substituted for the genuine article in potted chicken. Turkey and pork are said to be used in chicken salad.

Capons.--The castration of the male bird produces the capon, the flesh of which is very highly valued as being superior to that of the male or female chicken. Capons are much more extensively used in Europe than in the United States but are gradually coming into favor in this country. It is difficult to describe the difference between the taste of the flesh of the capon and the rooster and hen. A greater degree of tenderness and a more delicate taste characterize the flesh of the capon. In France, especially, the production of capons has been carried to its highest perfection. Caponizing should be practiced at an early date in the life of the young bird. In fact, as soon as the distinction in sex is well marked in the young chicken the removal of the testes should take place. The young fowl is laid upon its left side and the skin is exposed by pulling back the feathers and trimming them off at the proper place until the space between the first and second ribs of the right side is laid bare. An incision is then carefully made and the testes removed by instruments particularly adapted for that purpose. The operation should be done by an expert although theoretically it appears easy of accomplishment. In practice, however, it requires an expert to avoid any injury to the bird and to insure a speedy recovery. When done in the proper way, apparently no great inconvenience attends the operation. There is little blood shed and usually no inflammation when the proper antiseptic measures are provided.

The capon develops a bird that apparently has little to do except grow fat and prepare itself for the market. The caponized bird often develops brooding instincts and when eggs are hatched by the heat of the bird the capon makes a better brooder than the hen because of the greater spread of the wings and the larger number of eggs that can be covered in the operation. The larger breeds of birds make the best capons such as the brahmas and plymouth rocks. The capons are fattened and prepared for the market as in the case of other birds. When skimmed milk is made a large portion of the diet the flesh is considered to be of greater value. The best age for marketing a capon is at about twelve months. At that time they have attained their full size and their maximum degree of excellence as a food bird. The feeding should be done upon the principles already described, namely, to keep the birds growing in the usual way until about three or four weeks before the market when the extra food is given in as large quantities as possible for quick fattening. In Europe this extra food is usually given mechanically under the forced system though in this country the mechanical method of feeding capons has not generally been introduced.

Capons bring a higher price upon the market than the other varieties of chicken, sometimes the difference being as much as four or five cents a pound. For this reason the growth of capons becomes more profitable to the farmer than that of the ordinary chicken.

=Duck= (_Anas boschas_).--The domesticated duck is used very largely for food in all parts of the world. Its flavor is not so highly prized as that of the wild duck but it is an excellent article of diet. The production of ducks is conducted in the same manner as the production of poultry in general. They are still chiefly grown upon the farm without any special care but the best results are obtained by the systematic growth of ducks under scientific conditions in poultry houses. The duck is not so extensively used for food as the turkey and chicken but perhaps in this country much more extensively than the goose. The price of the wild duck, however, is still

sufficiently low to limit to a certain extent the production of the domesticated article.

Varieties of Ducks.--There are many varieties of ducks cultivated for the market. The Pekin is perhaps the most abundant of all. It is creamy white in color, has a long and graceful body and has been particularly bred for the market. When ready for the market the average weight of the drake is about eight pounds and the duck seven. The Aylesbury is also a favorite variety. It is said to be somewhat whiter than the Pekin in color. It is specially valued in England as a market duck. It is somewhat larger than the Pekin. Other varieties of ducks are the Rover, the Cayuga, the Gray and White Call, the East Indian, the Crested White, the colored and white Muscovy, and the Indian runner. The latter is a very small duck, being only about one-half the size of the Pekin. Usually the ducks on the market are not designated by any particular variety and, in fact, most consumers are not sufficiently acquainted with the different varieties of duck to be able to ask for any particular one. The mallard, canvas-back, and teal are common varieties of the wild duck.

Composition of the Flesh of Ducks.--The flesh of two varieties of ducks, namely the Pekin duck and the Mallard duck, was carefully separated in the Bureau of Chemistry and subjected to analysis. The composition of the meat of these two ducks is shown in the following table:

WATER IN FAT-FREE MEAT WATER. SUBSTANCE. FAT. PROTEIN. BASES. Percent. Percent. Percent. Percent. Percent. Pekin duck, 47.46 78.20 39.31 13.37 .43 Mallard duck, 69.06 75.98 7.11 19.25 .65

The above data show a striking difference between these two varieties of ducks. The Pekin duck has a large excess of fat while the Mallard duck, which is a wild duck and evidently not very fat, has a small percentage of fat and a large percentage of protein. It is evident that the flesh of wild fowl would not, except at a certain season of the year, approach that of domesticated fowls in the percentage of fat which it contains.

=Goose= (_Anser anser_).--The goose is not so commonly used as a food product in this country as in Europe,--the turkey to some extent has taken its place. The remarks which are applicable to the production of chickens are also applicable to the production of geese. They, perhaps, are grown more extensively in the old-fashioned way in this country than chickens or turkeys at the present time since they are used chiefly for the feathers which they produce and not for food. Goose is also considered a winter dish both in this country and in Europe. It is customary in Europe that the goose be hung even for a longer period before consumption than the chicken. Its flesh is made more tender and more palatable by this preliminary exposure. From one to two weeks is not considered too long a time in the winter for hanging in the old country. The remarks relative to cold storage of turkey and chicken apply also to the goose. The goose is, perhaps, the most easily artificially fattened of any other poultry birds. This is especially true in those regions where fatty goose livers are so highly prized in the manufacture of _pâté de foie gras_. By long-continued artificial feeding the goose is made excessively fat and the liver especially is changed in its composition by this treatment so as to make it peculiarly suitable for the production of this delicacy.

Varieties of Geese.--The varieties of geese upon the market comprise the following leading breeds. The Toulouse is perhaps the most extensively raised. It is highly prized on account of its hardihood, its size and the general appearance of its body. It is of a gray to white color and the wings are a deeper gray or brown. The legs are usually of a deep orange. When ready for the market the average weight of the gander is 20 pounds and the goose 18. Of the other common varieties there are the Embden, the African, the brown and white Chinese, the white or Canada, and the Egyptian. The latter is a small goose only weighing about half as much as the Toulouse when ready for the market. The wild goose is highly esteemed as a game bird.

Feeding of Young Geese for the Market.--The feeding of geese for the market begins as soon as the hatching is complete. The first meal of the young chicks consists of oat meal, middlings, finely chopped dandelions, lettuce or some similar green stuff, and milk. The goslings during the first week are kept indoors and should be fed four or five times a day on the mixture above named. After this they may go into a yard where there is plenty of grass, not overgrown, and they will thrive on this very well for a time without hand feeding. Not more than two feedings a day are necessary between the ages of one and six weeks where plenty of grass is at hand. During this time no better food than ground oats and skimmed milk can be used. During all this period great care is taken that the goslings are not subjected to any disease or to cold. They should be carefully housed in sanitary coups where the temperature does not sink too low and where they are protected from cold rains. After the goslings are eight weeks old they are usually able to take care of themselves in respect of food and need, perhaps only one feeding a day. If these goslings are hatched in the early spring they may be ready for fattening for the Christmas market. The geese until shortly before the time for market are

allowed to run free in a field, not too large, where there are ponds or troughs of water in abundance. In this way the frame of the goose will be sufficiently developed by the time the fattening period comes but there will have been no unusual expense in the production of the fowl until it is prepared for the market. The large frame is necessary in order that the goose may properly fatten. It usually requires about three weeks of artificial feeding to bring a goose into proper condition for the market. If the geese are for the Christmas market about the 25th of November they are put up in sheds for fattening for though they have been well fed during the summer and autumn they cannot be called fat geese until they have gone through a special course of nutrition. While they are confined for fattening, geese require plenty of fresh air but very little light and these conditions are procured by housing them in large airy sheds without windows. Before the fattening season these sheds are thoroughly cleaned and whitewashed and the floor covered with cinders, ashes, and charcoal. This mixture is not only a good bedding but is also a good deodorizer, which is quite important. Food troughs are arranged along the walls inside the shed and troughs for water outside in such a way that the birds can reach the water but cannot get into it. Clean charcoal is to be put into the shed every day as it is constantly eaten by the geese and is valuable. The foods used are oat meal, boiled potatoes, linseed meal or other oil cakes, and plenty of milk, usually skimmed. The birds should have all of this that they can eat, for in the process we are now describing the artificial forcing of food into the craw is not practiced. In three weeks a good goose will increase four or five pounds in weight and this increase brings the goose up from an ordinary bird in good condition to one which is properly fed for the market.

The killing of geese is practiced in practically the same manner as that which is described for slaughtering fowls. A goose is a bird of large vitality and dies hard as is the case with most fowls. The feathers should be taken off the body clean, as they are valuable for commercial purposes. Any pin feathers should be cut with a sharp knife so as to make the bird look as clean as possible when brought to the market. The carcass of the goose should not be packed to send to market until it is entirely cold and in this country, especially, where the distances are great, it is advisable to send it packed in ice or in a cold storage car. The average weight of a goose about nine months old thus prepared for the market is about fourteen pounds and the flesh is certain to be more palatable at this age when fattened in the manner above described.

=Domesticated Pigeon= (_Columba livia_).--In the last few years the production of domesticated pigeons has been extensively practiced in this country, and especially the production of young pigeons which are known as squabs. They are rapidly taking the place of game birds at the hotels and restaurants of the country. The conditions of production, preparation, etc., are the same as those for the ordinary domesticated fowl. There are many varieties of the bird grown; some, as the carrier, for special purposes. The other principal varieties are barbs, fantails, jacobins, runts, trumpeters, tumblers, and turbits.

=Turkey= (_Meleagris americana_).--In general the statement which has been made regarding the production of fowls or chickens may be applied also to the production of turkeys. No further comment, therefore, is to be made under that head. The old-fashioned method of securing turkeys grown under natural conditions has, to a great extent, given way to the production of turkeys on a large scale and under scientific conditions. Turkeys, as a rule, are not eaten young, but practically full-grown. In this country the turkey is a dish which is particularly affected for festive occasions such as Thanksgiving and Christmas, though they are eaten largely throughout the whole year. The market, however, for turkeys is particularly a November and December market and the large introduction of turkeys in the market is so timed as to furnish them in proper condition for consumption during those two months.

The methods of preparing turkeys for the market, keeping them in cold storage, of hanging them previous to consumption and exposing them drawn or undrawn for sale, are subject to the same remarks as has been made in the case of chickens. Turkeys are said to be more difficult to care for, both on the farm and in the professional poultry factory, than chickens. They are more subject to disease and more difficult to bring to maturity than chickens.

Composition of Meat of Turkey.--The flesh of the turkey was separated into two portions, the white and dark meats, and these were found to have the following composition:

WATER IN FAT-FREE MEAT WATER. SUBSTANCE. FAT. PROTEIN. BASES. White meat, 55.50 74.70 25.71 18.31 1.31 Dark meat, 54.13 75.76 27.76 16.75 1.15

A comparison of these two analyses show that there is little difference in the content of water in the white and dark meat. The dark meat, as in the case of chicken, has more fat and a correspondingly less amount of protein. The quantity of protein in the meat of turkey is about the same as that of chicken. The white meat of turkey differs from the white meat of chicken more in its content of meat bases than in any other way, except that the meat of turkey contains more fat, especially the white meat, than that of chicken.

=Composition of the Meat of Chicken, Turkey, Duck, and Goose.=--The composition of the chicken, turkey, duck, goose, and pigeon as given by König is found in the following table:

WATER. PROTEIN. FAT. ASH. Chicken (lean), 76.22 19.72 1.42 1.37 Chicken (fat), 70.06 18.49 9.34 .91 Young cock (fat), 70.03 23.32 3.15 1.01 Turkey, 65.60 24.70 8.50 1.20 Duck (wild), 70.80 22.65 3.11 1.09 Goose (fat), 38.02 15.91 49.59 .48

The above data show that with the exception of the goose the percentage of fat given in the flesh of the animals is very much less than that found in our own work. Even in the fat chicken only a little over 9 percent of fat was found. It is believed that the composition of these fowls as given by the work of the Bureau of Chemistry more nearly represents the average composition in this country than the data taken from König.

=Importance of Animal Food in the Growth of Poultry.=--Many people suppose that poultry can live upon vegetables alone and this is probably true. Experience, however, shows that poultry does not thrive and fatten well on purely vegetable food. This fact was brought out very prominently in the experiments at the Cornell station where poultry of the same origin and character was fed two kinds of diet, one being partly of animal food and the other purely vegetable foods. The ration of the animal food consisted of Indian corn meal, wheat flour, ground oats, wheat bran, wheat middlings, pea meal, linseed meal, meat, and fresh bone. The vegetable ration consisted of pea meal, linseed meal, wheat bran, ground oats, Indian corn meal, wheat middlings, gluten meal, and skimmed milk. Before the experiment had been long under way it was noticed that the birds receiving the meat food were developing rapidly and evenly while those that received the purely vegetable diet were becoming thin and uneven in size. The authors of the bulletin say that it was sometimes almost pitiful to see the long-necked, scrawny, vegetable-fed birds, with troughs full of abundant good, wholesome food before them, stand on the alert and scamper in hot haste after the unlucky grasshopper or fly which ventured into their pen, while the contented looking meat-fed ducks lay lazily in the sun and paid no attention to the buzzing bee or crawling beetle. The vegetable-fed birds literally starved to death, at least many of them, so that only twenty of the thirty-three with which the experiment was commenced were alive at the close of the fifteen weeks of feeding.

=The Forced Fattening of Poultry.=--Allusion has already been made to the forced fattening of poultry secured by injecting food into the craw in larger quantities than would naturally be taken by the fowl if left to itself. There is much to be said both for and against this method of fattening. In favor of this method it may be stated that the birds fattened in this way are more highly prized by the connoisseur, are naturally fatter by reason of the enforced idleness of the birds during the fattening process, thus diminishing muscular activity, and more tender than the birds left at freedom and forced to secure their own food. From the point of view of the seller, also, the birds are heavier and the artificially fattened fowl usually brings a higher price, pound for pound, on the market. Against the method it is urged that it is barbarous, imposing upon the birds a diet far beyond normal capacity and thus tending to damage and injure the organs of the body charged with the assimilation of food and the secretion of the waste products.

The above indictment is doubtless true is almost every respect. In explanation it may be said that the period of forcing food is always a short one, rarely extending beyond three weeks, and, therefore, any injury to the organs which might be induced is not of sufficient duration to establish any real form of disease. In other words, the birds are slaughtered before any lesions of the organs are produced. The livers of the animals, especially geese, thus artificially fattened, take on an extra quantity of fat during this period but it cannot be said that they become really diseased. The fatty livers, as is well known, are used particularly in the manufacture of a mixed spiced meat known as _pâté de foie gras_.

Upon the whole it is believed that no injury is done the bird by this process of feeding which could in any way be regarded as detrimental to the flesh as a food product. In regard to the apparent barbarity of the process little need be said. The slaughter of animals for human food in itself is a barbarous practice from one point of view but if this practice is justified, as it doubtless is, by the exigencies of human nutrition, the slight degree of force which is employed in artificial fattening cannot be condemned. Moreover the artificial fattening of the fowl is of necessity a somewhat limited operation and confined to those establishments that are devoted exclusively to the production of high-grade and high-priced poultry for the market. The fattening is done by experts and, in so far as the experience of feeding men in the same way is concerned, is not attended with any pain or discomfort other than that incident to a chronically full craw.

Increase in Weight.--There is a larger increase in the weight of artificially fattened poultry over those fed in the ordinary way and allowed to run free than is usually supposed. It is stated by some authors that the average increase in weight of artificially fattened birds is as much as 35 percent. There is no secret connected with the method of artificial fattening as is sometimes supposed. There are perhaps proprietary methods for preparing foods for fattening purposes but there is no secret in the mechanism of the

process. In fact the process is so simple that it might be easily taught in a general way so that the farm hand would become an expert in its use and the farmer's poultry instead of being sent to market in a half-emaciated condition might be offered to the public in the best possible shape. Poultry running at large use up a large part of the value of their food in the heat and energy developed in the ordinary search for food. When confined and fed artificially this excess of heat and energy is naturally stored as fat.

Experience has shown that the artificial feeding must be a limited one and the bird must be sent to market as soon as it has reached its maximum of perfection under the process. Experience has also shown that in the artificial feeding it is best to have each bird in a small compartment to itself with the cage so arranged that the bird can put its head through a slat in front and thus receive the food from the machine without disturbing any of its neighbors. That the birds are perfectly willing to take the food in this way is evidenced by the fact that they voluntarily put their heads through the apertures to receive their food. Each individual coup must be kept scrupulously clean and disinfected and the air in the room kept perfectly fresh and sweet. Lime should be used freely in all parts of the coup house in the form of whitewash or sprinkled about the floor or upon the floors of the coups. Gypsum or ordinary land plaster is also highly prized as another form of lime which is found to be very valuable. The whitewash must be freely indulged in and at frequent intervals.

There are various forms of fattening food used in this country. Indian corn meal forms an important part. The presence of certain animal products must not be neglected in the food as it has been shown that fowls thrive better when given, in their food, a certain amount of animal matter, both of flesh and finely ground bone. The fattening food must be in the form of a finely ground paste of the proper consistency to be handled well in the machine. It is a universal practice which custom has shown to be necessary to mix with the food a certain quantity of finely pulverized charcoal, usually about three pounds of the charcoal to 97 pounds of food. Some feeders prefer to mix the paste about twenty-four hours before it is administered, believing that the slight fermentation thus produced is beneficial.

The Cramming Machine.--Various forms of machines are employed for introducing the food into the craw. The tube carrying the food is introduced into the esophagus of the bird in a manner to avoid any pain and the apparatus is so adjusted that with a single movement of the machine, usually operated by the foot, the proper amount of food is injected. The birds should be arranged according to size so that all of a certain size may have exactly the same quantity of food administered. The operator would thus be saved the difficulty of guessing the different sizes. The arrangement of the coups and the kind of the cramming machine vary greatly. In the beginning of artificial feeding the birds should not be pushed to their full capacity. An increasing quantity of food should be given up to the end of the first week or ten days before the full maximum dose is administered. In general it is found best to take the bird out of the coup for feeding, holding it under the arm so that the neck can be made perfectly straight and gently inserting the flexible tube which carries the food and thus with the single movement of a lever, filling the craw. The use of the machine, however, is found to be advantageous from a point of economy although it is claimed that the cramming of birds by means of a funnel has been found very efficacious. With a good machine an expert operator can feed about 250 birds in an hour. An important point in the fattening is that the food should be given regularly.

=Slaughtering Fowls for the Market.=--It is important that a uniform and proper method be used for killing fowls intended for the market. There are two methods in common vogue, namely, by bleeding and by dislocation of the neck. The method of killing is important in order that the proper method of dressing for the market may be secured. A fowl which is offered for sale ought to be attractively dressed and any brutal or defacing method of slaughter makes it impossible afterwards to render the fowl attractive to the customer.

In killing by the dislocation of the neck the operator takes the bird by the thigh and top of the wing in the left hand and the head in the right and then draws it steadily until dislocation takes place. The skin remains unbroken and no bruised effect is produced but all the blood in the body drains into the neck and remains there. This method is one especially practiced in England (Journal, Board of Agriculture, 1904-5, page 306). Where the bird is very large, as is the case with turkeys, it may require the full strength of a man in order to produce the dislocation in the manner mentioned. In this case it is often necessary to first hang the bird up by the leg to secure the best results.

In killing a fowl by bleeding it is strung up by the legs with its head hanging downward. The operator then gives it a sharp blow with a stick on the back of the head and when he has stunned it by this means he inserts a sharp knife into the roof of the mouth, penetrating the brain. He also severs the large artery of the throat by rotating the knife and the bird rapidly bleeds to death. This method of killing, it is seen, is not a very humane one. If, for instance, the sensation of the bird is not destroyed by the first blow the other process must be needlessly painful. This process, simplified somewhat by omitting the hanging, is the one commonly

followed by professionals in this country. In England turkeys which are prepared for the market are plucked but not drawn. One of the newest methods of plucking is known as the Devonshire style and consists in stripping the feathers clean off the breast and thighs but leaving the neck, back and wings covered. The fowls are then tied around the legs with a strong cord in such a manner as to show the plumpness of the breast prominently.

The methods of preparation of the fowls depend largely on the demands of the market to which they are going. Some require the fowls to be clean plucked and others prefer some of the feathers left on.

=Eggs.=--Eggs are a common article of diet throughout the world. The eggs of domesticated fowls are those which are principally used for food, though the eggs of wild fowls, and birds and reptiles are also edible but on account of the difficulty of getting them and their rarity are not to be considered as a commercial article. The chief sources of supply are the eggs of chickens, ducks, and geese. Chicken eggs are by far the most important, duck eggs the next important, and goose eggs the least important. The eggs of fish also constitute an article of food of considerable value and are extensively used. For instance the fresh eggs of shad are used in large quantities during the whole of the shad season and are often kept in cold storage for use at other times. The eggs of sturgeon are used extensively in the fresh state and when pickled as caviar are highly esteemed throughout the world. These two kinds of eggs are probably the most important of fish eggs used for food purposes. Chicken eggs vary greatly in size according to the age and variety of the fowl. The average weight of chicken eggs is 680 grams per dozen. They vary also in color from pure white to a brownish yellow. Duck eggs are larger and also variegated in color. The average weight of duck eggs is 847.2 grams per dozen. Goose eggs are the largest of the three varieties, varying also in color. They weigh on an average 2284.8 grams per dozen. Eggs also vary greatly in shape, being generally ovoid but some being much more spherical than others according to the species of the fowl and variety. The number of eggs which a chicken will lay varies greatly. Attempts have been made, with great success, at experiment stations, to develop chickens with high laying powers. A hen which will produce over 200 eggs a year is regarded as a high-grade fowl for egg-producing purposes. Eggs are produced more abundantly during the early spring and summer than during the winter months. One of the purposes of scientific egg producing is the development of fowls that will produce eggs more evenly throughout the whole year, thus avoiding the very great depression in the price of eggs in the spring and the excessively high price of eggs in the winter.

Composition of Eggs.--A large number of eggs have been analyzed in all quarters of the world and found to vary but little in composition in different localities, and very little also in regard to the variety of the fowl. The egg consists essentially of two portions,--an external highly albuminous portion known as the white and an internal colored portion, yellow or reddish in tint, known as the yolk. The white of an egg is composed almost entirely of albumin partially dissolved in water. The yolk of the egg is composed of albumin, fat, and a phosphorus-bearing material of high nutritive value known as lecithin. The yolk of an egg is a much richer food product than the white, containing in addition to the nitrogenous element the fat and mineral bodies necessary to nutrition. Both the white and yolk of an egg are composed principally of water as will be seen by the following analytical data:

COMPOSITION OF EDIBLE PART OF EGGS.

WATER. PROTEIN. FAT. ASH. CALORIES. Percent. Percent. Percent. Percent. Per pound. Hen, 73.7 13.4 10.5 1.0 .... Duck, 70.5 13.3 14.5 1.0 985 Goose, 69.5 13.8 14.4 1.0 985 Turkey, 73.3 13.4 11.2 0.9 850

Preservation of Eggs.--Freshly laid eggs may be preserved for several days without any notable deterioration by keeping in a cool place. The temperature of preservation should be as nearly the freezing point as can be secured. The vital processes are continually going on in a fresh egg and hence there is a development of a certain degree of heat due to these activities. For this reason eggs can be placed in an atmosphere below the freezing point of water without being frozen. An additional reason for this is found in the fact that the water which is present in eggs holds the albumin and other bodies in solution and the freezing point of a solution is always lower than that of the solvent alone. For domestic purposes where refrigerating establishments are not available the fresh eggs should be kept in a cool dark place where the temperature is not allowed to go above 50 or 60 degrees. At a higher temperature than this fresh eggs lose their freshness in a remarkably short time. The porous nature of the shell is a condition which favors the deterioration of the egg by the admission of air and microbes into the substance of the egg itself.

The preservation of eggs is, therefore, materially assisted by coating the egg artificially with a varnish or film of some kind which renders the egg impervious to air and water. One of the cheapest, simplest, and best of these coatings, as has already been noted, is soluble glass. This is produced by dissolving the chemical substance known as silicate of soda in water, and dipping the egg into the solution, removing and allowing to dry. The silicate of soda which is thus left in a thin film over the surface of the egg penetrates

and stops the pores and renders the egg shell practically impervious both to air and water. This material has the property of becoming totally insoluble in water when it has once been dried so that even if the egg is afterwards subjected to rain or water in any form the film is not removed. Many other methods of coating eggs have been employed and are dependent upon the same principle but are perhaps not so effectual and simple as the inexpensive method above described.

Cold Storage.--Eggs either with or without the coating of the surface, usually without, may be kept for a considerable length of time without deterioration in cold storage. In this case it is advisable to reduce the temperature to the lowest possible point to retain the semi-fresh condition of the contents. Water freezes at 32 degrees, but for the reasons above mentioned the temperature at which the egg is stored may be reduced notably below 32 degrees without danger of solidifying. The eggs kept in cold storage gradually acquire a taste and aroma which are quite different from the fresh article and the period of preservation should never be prolonged, probably a month or six weeks is the extreme limit for keeping eggs which can still be regarded as having the qualities of the fresh article. In practice, eggs are kept often a very much longer time since the principal object of cold storage is to lay in a supply in the spring and summer when they are abundant and keep them over until the next winter. The average age of cold storage eggs is probably more than six months. At this time the eggs have acquired a distinctly unpleasant odor and flavor which enables even one who is not an expert to distinguish between them and the fresh article. Such eggs should not be allowed on the market except under their proper designation so that the purchaser may know the character of the product he is getting. There is a determined opposition on the part of those dealing in cold storage eggs against such marking, an opposition which can only be explained by the fact that the amount of deterioration is fully as great as specified. If cold storage eggs have not been kept long enough to develop any of the objectionable conditions mentioned above and are inferior only in respect of taste and aroma there seems to be no just reason why they should be forbidden sale. They usually bring a lower price than fresh eggs produced at the time of sale and thus are brought more readily within the means of those who are less able to pay the higher prices. Cold storage eggs are extensively used for baking purposes and in this condition escape the detection of the consumer. This appears, however, to be no just reason for their use without notice.

Broken Eggs.--An extensive industry has been practiced for many years in the product known as broken eggs. In the preparation of broken eggs at times of great abundance, the eggs are collected and broken and then mixed together in containers of various sizes, often as large as barrels, and preserved by the admixture of borax. From two to four pounds of borax are usually employed per 100 pounds of broken eggs. In this condition the eggs are kept from the time of great abundance until the time of higher prices, namely, from six to eight months, and then sent into commerce. The use of broken eggs of this kind for edible purposes is totally indefensible. While borax prevents the development of bacteria it does not entirely inhibit enzymic action and hence that subtle change of nitrogenous matter which produces poisonous bodies may go on in the presence of borax while apparently the egg itself remains undecomposed. Broken eggs were formerly sent to this country in large quantities from China and other Asiatic countries but since the passage of food inspection laws as applied to foreign commerce the importation of this class of food products has been prohibited, on the ground that they are unfit for human consumption. Other preserving agents have been used in place of borax for these products, but all are open to similar objections. Broken eggs are used chiefly by bakers in large cities.

Dried Eggs.--The rapid drying of fresh eggs is perhaps an unobjectionable method of preservation. The drying may take place by spreading the eggs in a thin film on a dry surface, which is the usual method, or by forcing the egg product through small orifices under a high pressure into a drying chamber so adjusted as to temperature and size as to secure the desiccation of the minute particles of egg spray before they fall to the bottom. This method is perhaps the best which has yet been developed in the desiccation of such products. The egg powder thus formed is almost devoid of moisture and when properly collected and stored out of contact with the air, may be kept for a time without deterioration. Dry egg products such as have been described made from fresh eggs, may be considered unobjectionable for a reasonable length of time. Unfortunately dried products are sometimes made from decayed eggs. During the past year a factory making a product of this kind was discovered by the food inspector of one of our large cities.

Egg Substitutes.--Many products have been put upon the market of a yellow color and containing protein under the guise of eggs. There is a number of so-called egg powders offered for making cakes, etc., which contain no egg at all. They are composed of other forms of protein matter, generally casein from milk, and colored to resemble the egg in tint. Starchy substances are also colored and sold as egg powder. These substances may be regarded as adulterations when sold under the name or in the guise of an egg product. There are no other adulterations of eggs of any consequence practiced except the simulation of egg material by such products as those just mentioned.

Poisonous Principles in Eggs.--While fresh eggs for most people form a food product entirely devoid of danger, nutritious and easily digestible, eggs may easily become injurious and even poisonous. According to experiments made by Bouchard (Scientific American, August 11, 1896, page 95), even fresh eggs, unless the sanitary conditions in which the fowls live are well cared for, may become very poisonous. The fowl producing eggs, as a rule, is not a cleanly animal, and this is especially true of the duck. Thus injurious organic material rich in microbes may contaminate the egg and the microbes may penetrate the shell thus rendering the egg unsuitable for consumption. Eggs contaminated in this way have given evidence of toxic phenomena even in a fresh state. Experiments have shown too that the food material of eggs if directly injected into the blood of an animal produces toxic effects whereas if injected into the stomach no unfavorable effects are produced. Egg albumin, that is, the albumin of the white of the egg, when fed in considerable quantities to animals partially escapes digestion and thus becomes a source of irritation and even of poisoning. There are many people who are remarkably sensitive to the influence of eggs and those who possess this idiosyncrasy are injured even by eggs which are perfectly harmless to other people. A large number of species of injurious microbes which infect eggs have been identified. These even are found in fresh eggs in the unsanitary conditions above mentioned. Eggs kept for a long while in cold storage or decayed in any way are extremely injurious. Fortunately decayed eggs are self protecting since they can only be eaten by accident. If, however, decayed eggs be eaten in diluted form by mixing with other foods they may be eaten without their characteristic odor or taste being known and thus great injury arises. It is advised in all cases where eggs are to be kept for some time even in cold storage to varnish them with some substance impenetrable to air. For this purpose, as has already been mentioned, soluble glass, which is chemically a silicate of soda, has been found extremely effective. Any of the varnishes which make the shell of an egg air tight tends to restrain the activities of bacterial life since the bacteria cannot live without air. The officials who inspect food should direct special care to the storing of eggs in order that no damage may result from keeping them too long in cold storage or otherwise. It must not be understood that poisoning by eggs is of common occurrence. In fact it is very rare. The fact that the egg itself, which is such a common article of diet, may be unsanitary and improperly kept is a matter of great concern to the consumer.

Parasites in Eggs.--The egg also when produced in unsanitary conditions may become infected with parasites. Many of these are apparently harmless, but some are injurious and even dangerous. The mere fact that parasites may exist in eggs is of itself a sufficient reason for the consumer to insist that the eggs he eats, like the milk he drinks, shall be free from all infections due solely to carelessness in production.

PART III.

FISH FOODS.

FISH.

Fish furnish a very important and useful part of the animal food of man. Both the fish growing in fresh water and in salt water are generally edible. Usually the smaller-sized fish are considered more palatable, but this is not universally the case. The large-sized fish are apt to be coarse, and have a less desirable flavor than those of smaller size. The size of the fish usually depends upon the magnitude of the body of water in which the species grow, the largest being in the lakes and oceans, the medium-size in rivers, and the smallest in brooks. Fish are known chiefly by their common names, and these names are different for the same species of fish in different parts of the country. For instance, the term trout covers a multitude of species, and, likewise, under the term sardine a large number of different species or varieties of fish are considered. There is also a large number of varieties known as salmon, perch, bass, etc.

In the following table are given the common and the scientific names of the principal food fishes used in the United States (see Report of U. S. Commission of Fish and Fisheries, 1888, pages 679-868):

Acipenseridæ: _Acipenser sturio oxyrhynchus_, Sturgeon. _Catostomidæ_: _Moxostoma velatum_, Small-mouthed red-horse. _Clupeidæ_: _Clupea harengus_, Herring. _pilchardus_, Sardine. _vernalis_, Alewife. _sapidissima_, Shad. _Salmonidæ_: _Osmerus mordax_, Smelt. _Coregonus clupeiformis_, Whitefish. sp., _tullibee_ or _artedi_, Ciscoe. _Oncorhynchus chouicha_, California salmon. _Salmo salar_, Salmon. subsp. _sebago_, Land-locked salmon. _Salvelinus namaycush_, Lake trout. _fontinalis_, Brook trout. _Esocidæ_: _Esox lucius_, Pike. _reticulatus_, Pickerel. _nobilior_, Muskellunge. _Anguillidæ_: _Anguilla rostrata_, Eel. _Mugilidæ_: _Mugil albula_, Mullet. _Scombridæ_: _Scomber scombrus_, Mackerel. _Scomberomorus maculatus_, Spanish mackerel. _Orcynus thynnus_, Tunny. _Carangidæ_: _Trachynotus carolinus_, Pompano. _Pomatomidæ_: _Pomatomus

saltatrix_, Bluefish. _Stromateidæ_: _Stromateus triacanthus_, Butter-fish. _Centrarchidæ_: _Micropterus salmoides_, Large-mouthed black bass. _dolomieu_, Small-mouthed black bass. _Percidæ_: _Perca fluviatilis_, Yellow perch. _Stizostedion vitreum_, Wall-eyed pike. _canadense_, Gray pike. _Serranidæ_: _Roccus lineatus_, Striped bass. _americanus_, White perch. _Centropristis atrarius_, Sea bass. _Epinephelus morio_, Red grouper. _Sparidæ_: _Lutjanus blackfordi_, Red snapper. _Stenotomus chrysops_, Porgy. _Diplodus probatocephalus_, Sheepshead. _Sciænidæ_: _Sciæna ocellata_, Red bass. _Menticirrus saxatilis_, Kingfish. _Cynoscion regale_, Weakfish. _Labridæ_: _Hiatula onitis_, Blackfish. _Gadidæ_: _Phycis chuss_, Hake. _Brosmius brosme_, Cusk. _Melanogrammus æglefinus_, Haddock. _Gadus morrhua_, Cod. _Microgadus tomcod_, Tomcod. _Pollachius virens_, Pollock. _Pleuronectidæ_: _Hippoglossus hippoglossus_, Halibut. _Platysomatichthys hippoglossoides_, Turbot. _Paralichthys dentatus_, Flounder. _Pseudopleuronectes americanus_, Flounder. _Petromyzontidæ_: _Petromyzon marinus_, Lamprey eel. _Raiidæ_: _Raia_ sp., Skate.

Some of the scientific names in the above list have been modified by recent research, but it is advisable to present the above classification for purpose of reference. The variations from these names will be given in the part of the discussion relating to the food value of fish, in which the classification of Jordan and Evermann is followed.

=Edible Portion of Fish.=--As in the case of other animals large parts of fish as taken from the water are inedible. In the preparation of fish the head is usually removed, especially if the fish be of any size, and the entrails rejected. If the fish be scaly, the scales are also removed. The latter vary very greatly in different specimens according to species, size, etc. Usually the edible portion of the fish is larger in quantity than the inedible, though this is not by any means universally the case. Taking fish of all kinds together it may be said that from 55 to 60 percent of the total weight is edible. This, of course, excludes the bones as well as the other portions already referred to.

=Principal Constituents of the Flesh of Fish.=--In the flesh of cattle, swine, and other edible animals already mentioned it is seen that the protein is the principal part of the edible portion. In many kinds of meat, however, the fat is the principal portion, as in bacon. In the flesh of fish the albuminoids occupy a more prominent part than in the flesh of domesticated animals or game. In other words the proportion of fat, which is one of the principal ingredients of the flesh of other animals, is less than in the other kinds of flesh. The protein in the water-free substance often constitutes over 90 percent of the total matter, and rarely falls below 80 percent. The next most important constituent of the dry flesh of fish naturally is the fat. The average content of fat in the dry flesh of fish is under 10,--it rarely goes above 20 and sometimes falls as low as 2 or 3 percent. The mineral content of the dry flesh of fish is quite constant. It rarely falls below 4 or goes above 8 percent; 5 percent may be regarded as a fair average content of mineral matter. The mineral matter consists chiefly of phosphate of potash and lime, together with some common salt. In the analyses made by Atwater, adopted in the following pages, he grouped together the fish analyzed in proportion to the quantity of the edible portion or flesh which they contained. Groupings were also made on account of the dry substance in the flesh and in proportion to the water and fat which they contained. These tables are of value showing in a general way the relative food importance of the different specimens of fish. This classification is given in the following table:

CLASSIFICATION OF FISHES BY PERCENTAGES OF FLESH, CHIEFLY MUSCULAR TISSUE IN ENTIRE BODY.

------------------------------+---------+---------- | NO. OF | |SPECIMENS| KINDS OF FISH. |ANALYZED.| FLESH. ------------------------------+---------+---------- _Containing 60 percent or over| |_Percent._ of flesh._ | | Spanish mackerel | 1 | 65.4 Salmon | 4 | 64.7 Red snapper | 1 | 60.0 | | _Containing between 60 and 70 | | percent of flesh._ | | Smelt | 2 | 58.1 Pike (pickerel) | 1 | 57.3 Cisco | 1 | 57.3 Butter-fish | 1 | 57.2 Spent salmon | 2 | 56.4 Mackerel | 5 | 55.4 Pompano | 2 | 54.5 Lamprey eel | 1 | 54.2 Herring | 1 | 54.0 Pickerel | 2 | 52.9 Spent land-locked salmon | 2 | 52.7 Turbot | 1 | 52.3 Brook trout | 3 | 51.9 Muskellunge | 1 | 50.8 Alewife | 2 | 50.5 | | _Containing between 50 and 40 | | percent of flesh._ | | Shad | 7 | 49.9 Weakfish | 1 | 48.1 Cod | 2 | 47.5 Whitefish | 1 | 46.5 Small-mouthed black bass | 1 | 46.4 Striped bass | 5 | 45.1 Large-mouthed black bass | 1 | 44.0 Sea bass | 1 | 43.9 Winter flounder | 1 | 43.8 Lake trout, “Mackinaw trout” | 1 | 43.7 Kingfish | 1 | 43.4 Pike perch, “Wall-eyed pike” | 1 | 42.8 Mullet | 1 | 42.1 Tomcod | 1 | 40.1 Porgy | 3 | 40.0 | | _Containing between 40 and 30 | | percent of flesh._ | | Blackfish | 2 | 39.9 White perch | 2 | 37.5 Yellow perch | 1 | 37.3 Pike perch | 1 | 36.8 Red bass | 1 | 36.5 Sheepshead | 1 | 34.0 Common flounder | 1 | 33.2 ------------------------------+---------+----------

CLASSIFICATION OF FISHES BY PROPORTIONS OF FAT IN THE FLESH OF SPECIMENS ANALYZED.

CLASSIFICATION OF FISHES BY PROPORTIONS OF WATER-FREE SUBSTANCE IN THE FLESH OF SPECIMENS ANALYZED.

----------+---------+---------- | NO. OF | |SPECIMENS|WATER-FREE KINDS OF FISH. |ANALYZED.|SUBSTANCE. ----------+---------+---------- _Containing over 30 percent of | |_Percent._ water-free substance._ | | California salmon | 2 | 36.4 Salmon | 5 | 36.4 Spanish mackerel | 1 | 31.9 Herring | 1 | 31.0 Lake trout | 2 | 30.9 Whitefish | 1 | 30.2 | | _Containing from 30 to 25 percent| | of water-free substance._ | | Butter-fish | 1 | 30.0 Shad | 7 | 29.4 Lamprey eel | 1 | 28.9 Turbot | 1 | 28.6 Salt-water eel | 2 | 28.4 Pompano | 2 | 27.2 Mackerel | 6 | 26.6 Alewife | 2 | 25.6 Small-mouthed black bass | 1 | 25.2 Mullet | 1 | 25.1 Porgy | 3 | 25.0 | | _Containing between 25 and 20_ | | percent of water-free substance._| | Halibut | 3 | 24.6 Sheepshead | 2 | 24.5 White perch | 2 | 24.3 Pollock | 1 | 24.0 Cisco | 1 | 23.9 Muskellunge | 1 | 23.7 Spent salmon | 2 | 23.3 Striped bass | 6 | 22.3 Brook trout | 3 | 22.3 Bluefish | 1 | 21.5 Red snapper | 3 | 21.5 Spent land-locked salmon | 2 | 21.5 Small-mouthed red-horse | 1 | 21.4 Large-mouthed black bass | 1 | 21.4 Sturgeon | 1 | 21.3 Weakfish | 1 | 21.0 Blackfish | 4 | 20.9 Smelt | 2 | 20.8 Kingfish | 1 | 20.8 Yellow perch | 2 | 20.8 Sea bass | 1 | 20.7 Grouper | 2 | 20.6 Pickerel | 2 | 20.3 Pike perch, “wall-eyed pike” | 1 | 20.3 Pike (pickerel?) | 1 | 20.2 | | _Containing between 20 and 15 | | percent of water-free substance._| | Pike perch, gray pike | 1 | 19.2 Tomcod | 1 | 18.5 Red bass | 1 | 18.4 Haddock | 4 | 18.3 Cusk | 1 | 18.0 Skate | 1 | 17.9 Cod | 5 | 17.4 Hake | 1 | 16.9 Common flounder | 2 | 15.8 Winter flounder | 1 | 15.7 ----------+---------+----------

In the scientific names of the food fishes described in the following pages and in the description of their habits, methods of spawning, geographic distribution, etc., the classification of Jordan and Evermann[15] has been followed.

[15] “American Food and Game Fishes,” by Jordan and Evermann, 1 vol., large 8vo, pp. i to l + 1 to 572. Twelve colored plates and several hundred full-page plates from photographs from life and text-figures. Doubleday, Page & Co., New York.

=Alewives.=--A fish belonging to a genus very close to that to which the herring belongs is known as alewife. The name of the genus is _Pomolobus_. It is commonly known as a herring. For instance, the fresh-water skipjack or blue herring,--the tailor herring or hickory shad,--and the real alewife or branch herring are all common species of this genus. One specimen of this genus is the fresh-water skipjack or blue herring (_Pomolobus chrysochloris_) found in the larger streams in the Mississippi valley and also in Lake Erie and Lake Michigan. It is strictly a fresh-water fish, but has also been found in salt water on the Gulf coast. The tailor herring is found along the Atlantic coast from Cape Cod to Florida. In the Potomac river it is known as tailor shad or “fresh-water tailor,” and is highly esteemed as a food fish in Washington and vicinity. Their value is found rather in their coming earlier than the shad than in their true value, for as soon as the shad come in great abundance there is no longer any market for the alewife.

Composition of Alewife.--

FRESH. DRY. Water, 74.41 percent Protein, 19.17 „ 75.87 percent Fat, 4.92 „ 19.08 „ Ash, 1.47 „ 5.78 „

This fish, it is seen, has very much less oil in it than the true herring,--in fact, only a little more than one-half as much. It, however, has a correspondingly larger percentage of protein.

The tailor herring and hickory shad are distributed along the coast from Cape Cod to Florida. The branch herring (_Pomolobus pseudoharengus_) is found along the Atlantic coast as far south as Charleston, entering fresh-water streams to spawn, usually two or three weeks ahead of the shad. It occurs also in Lake Ontario and in several of the small lakes in northern New York in which it is

land-locked. The summer herring (_Pomolobus æstivalis_) also occurs along the Atlantic coast.

=Anchovy.=--The anchovy is a small fish which is eaten more as a relish in the pickled state than in the fresh state, and is highly prized by many connoisseurs. Anchovies of various species are found on both the Atlantic and Pacific coasts,--on the Atlantic coast from Cape Cod to Brazil and on the western coast from southern California southward. These fish reach a length of from 2 to 7 inches. The very small ones are sometimes known as “whitebait.” Those that are pickled and used for food are usually from 3 to 6 inches in length.

Composition of Preserved Anchovies.--

Water, 57.8 percent Protein, 22.3 „ Fat, 2.2 „ Ash (principally salt), 23.7 „

=Black Bass.=--Two species of black bass are well known to the American fisherman and to the American cuisine. The one is called the small-mouth black bass (_Micropterus dolomieu_) and the other the large-mouth black bass (_Micropterus salmoides_). These fishes are found in the fresh waters of the United States, especially in the northern portion, almost everywhere. Both species have been propagated both by the National and State Fish Commissions. Especially have they been introduced into the northeastern waters where they originally did not occur, or only in small numbers.

=Bluefish.=--The bluefish (family Pomatomidæ) is one of the valuable food fishes of our Atlantic coast. It is a voracious, carnivorous fish, and apparently loves to destroy as well as to eat. It is stated that the bluefish copies after the style which was once said to be in vogue in Rome, viz., when its stomach is filled it disgorges it for the purpose of eating a new ration. The size of the bluefish runs from 3 to 5 pounds, though occasionally very much larger examples are taken. As a food fish it is said to rank in the estimation of the connoisseur with pompano and Spanish mackerel. The bluefish is one of the popular fishes in all the large markets of the Atlantic coast. The flesh has a fine flavor, but, like the pompano, it does not keep well.

Composition.--

FRESH. DRY. Water, 78.46 percent Protein, 19.02 „ 90.13 percent Fat, 1.25 „ 5.79 „ Ash, 1.27 „ 5.91 „

A comparison of the flesh of this fish with the pompano shows that it is particularly a protein food, the fat being even less abundant than the mineral matter. It, therefore, is not so well balanced a ration as the flesh of the pompano and other fish in which the fat forms a considerable portion of the edible matter.

=Carp.=--The carp is a fish used very largely for food purposes, but it has not the fine flavor and character of most fishes. The carp cultivated in America is known as the German carp (_Cyprinus carpio_).

The carp belongs to the large family of fishes known as the minnows or Cyprinidæ. This family is a large one, having about 200 genera and more than 1000 species, all of which are inhabitants of fresh water in North America and Eurasia. None of this family is highly regarded as food in the sense of flavor and aroma, except, perhaps, some of the smaller species. The nutritive value of the carp, however, is probably as great as that of any, but it is coarser and less attractive to the taste. Some of the most common species of this family are the dace, fallfish, river chub, creek chub, squaw-fish, and roach.

=Catfish.=--Catfish, of which there are many species, belong to the family of Siluridæ, and are among the most common fresh-water fishes found in the United States. They occur in small as well as large fresh-water streams and lakes, and it is one of the species which the American boy most delights in catching with hook and line. The catfish is most conveniently taken after night, and the smouldering fire and small boy on the bank of a stream is a frequent picture of American country life. There are more than 100 genera of the catfish family and about 1000 species. Only about one-third of the species inhabit salt water. The North American fresh-water species are confined particularly to the Atlantic coast, the Mississippi valley, and the Gulf states. There are no native species of the catfish in the fresh waters of the Pacific coast. The blue catfish, known as the Mississippi catfish, is the most prominent species (_Ictalurus furcatus_). It is found particularly in the Mississippi river and its large tributaries. Sometimes it grows to an immense size, individuals having been found reaching 150 pounds in weight. If the stream in which the catfish lives runs north and south it will be found in the southern part of the stream in the winter and in the northern part in summer. This fish is highly prized for edible purposes. In the small streams the catfish is correspondingly small and weighs from less than one pound to two or three pounds only. The small catfish, especially in the small streams tributary to the Ohio and Mississippi, has edible properties which are far superior to the large catfish growing in the rivers themselves.

The catfish of the small streams and lakes are commonly known as bullheads, since the head is large and wide. The name of the most common or best known species is _Ameirus nebulosus_. This species is found from Maine westward and southward. In Pennsylvania it is known as the Schuylkill cat, and everywhere generally throughout the country as a small catfish.

=Codfish.=--One of the most famous food fish of the American waters is the codfish. It is a widely distributed fish. There are said to be about 25 genera and 140 species. The codfish is particularly a fish of the northern waters. Only one genus is found in fresh-water lakes and streams.

=The Common Cod.=--The common codfish (family Gadidæ) is the species _Gadus callarias_. It is rarely found south of the Virginia coast, but is especially abundant off the New England and Newfoundland coast. The great center of the codfish industry is in the vicinity of Newfoundland. Gloucester, Massachusetts, is the principal town devoted to the codfish industry in the United States. The cod is an omnivorous fish and especially fond of crustaceans, mollusks, and small fish. It also eats vegetation, and it is stated by Jordan and Evermann that all sorts of things have been found in cod stomachs, such as oil cans, finger rings, rubber dolls, rocks, pieces of clothing, etc. The livers of the cod, especially those of Norwegian origin, are extremely valuable, being the source of cod liver oil, which is considered by many to be the most valuable medicinal food known. Cod liver oil, while not palatable, is highly nutritious. The cod livers contain, according to some authorities, over 60 distinct chemical substances, many of which are highly important for their medicinal qualities. The cod move in schools, but not in such dense bodies as the mackerel, herring, and menhaden. Their movements are largely controlled by the temperature of the water and their desire for food. This species probably does not reach a greater length than 3 feet and a weight of more than 25 pounds. The average weight of the large-size cod in New England waters is about 15 pounds and on the Grand Banks of Newfoundland 20 pounds. The average weight of the small-size cod in these waters is about 12 pounds. It is one of the most prolific of fishes. The ovaries of a 21-pound cod were found to contain 2,700,000 eggs and of a 75-pound cod 9,100,000 eggs. The eggs are very small and require about 337,000 to make a quart. The cod is one of the most valuable of all fishes from a commercial point of view and also on account of international relations. On some occasions this country has apparently been on the verge of war with Great Britain respecting questions relating to the fisheries on the banks of Newfoundland. The U. S. Bureau of Fisheries has probably done more to propagate the cod than any other variety of fish. More than five hundred million cod fry have been liberated at different times by the Bureau and the number in one year has approximated 100,000,000. The color of the common cod is green or brown, but is subject to very great variations,--sometimes it is yellow or red and a variety of tints are assumed.

Composition.--

FRESH. DRY. Water, 82.64 percent Protein, 15.77 „ 95.13 percent Fat, .36 „ 2.07 „ Ash, 1.23 „ 7.08 „

These data show that the flesh of cod fish is perhaps the most exclusively nitrogenous of any of the more abundant food fish. The quantity of fat contained therein is less than ½■■ of the total weight. The flesh of the fresh cod is more largely composed of water than that of the ordinary fish, containing approximately 83 percent of that substance. The flesh of the cod itself is an unbalanced ration, and needs to be eaten with butter and potatoes in order to make a complete ration. The hake, which is sometimes substituted for the cod without the knowledge of the purchaser, has very much the same chemical constituents, containing--

FRESH. DRY. Water, 83.11 percent Protein, 15.24 „ 91.00 percent Fat, .67 „ 3.97 „ Ash, .96 „ 5.77 „

It is seen that there is very little difference in the chemical composition of these two fishes. This, however, does not justify the substitution of the hake for the cod, inasmuch as the hake is inferior in palatability to the cod.

=Salted and Dried Cod.=--In the United States the cod is particularly devoted to the use of curing and salting, and in this cured state is even more highly valued, especially for the making of codfish balls, than it is in its fresh state. The old-fashioned method of salting and smoking produced a flesh of very high flavor, yielding under proper treatment in the kitchen a most delicious base for the fish ball. Under the modern system of quick curing, the salting and smoking have largely disappeared and the fish are cured in brine, and with the help of borax a product is produced which is less palatable than the old-fashioned cured fish.

Composition of dry Salted and Dried Cod.--

Protein, 45.65 percent Fat, .53 „ Salt, 53.82 „

These data show that more than half of the weight in the water-free state is composed of salt. The codfish is also put up as boned fish in which nothing but the flesh is found, as desiccated cod, as shredded codfish and in various other forms.

Average Composition of Codfish Balls.--

Water, 65.43 percent Solids, 34.57 „ Nitrogen, 1.05 „ Phosphoric acid, .25 „ Sulfur, .10 „ Fat, 7.84 „ Ash, 4.05 „ Protein, 6.58 „

The difference between the composition of the fish balls and the average composition of fish is clearly brought out by the data recorded. In the average composition of fish the sum of the fat, ash, and protein is greater than the solids obtained by difference by 0.36 percent. In the codfish balls the sum of the ingredients mentioned is less than the solids by difference by 16.10 per cent. This is due to the added potato, salt, etc.

Average Composition of Shredded Codfish.--

Water, 46.52 percent Ash (chiefly salt), 22.81 „ Fat, .33 „ Protein, 30.85 „

=Eels.=--The common eel is a fish which is extremely long in proportion to its size and gives the general appearance, to the uninitiated, of a snake. The resemblance of the eel to a snake in shape is probably one of the reasons why it is not more highly valued as a food. The eels, perhaps, are not to be considered as true fish. The common eel (_Anguilla chrysypa_) is widely distributed throughout most parts of the United States, especially the eastern part. It extends southward as far as the West Indies, and is found in more or less abundance on the Gulf coast. Although a salt-water fish, it differs from most other eels in its penchant for ascending fresh-water streams. It often goes to the very headwaters, especially in the rivers of the Atlantic coast and Mississippi valley. Eels are often found in lakes which seem to have had no communication with the sea, which shows that they are able to surmount barriers which seem impossible to cross. Jordan and Evermann claim that the eel is really a fresh-water fish and that its real home is in the fresh-water rivers and lakes, and that it runs down to salt water only at spawning time, thus showing a quality or characteristic exactly opposite to that of the salmon and shad, which are true salt-water fish and come into fresh waters for spawning. Eels, like the carp, are more or less scavengers, feeding upon all manner of refuse, especially dead fish. They are very destructive of other fish, especially of young shad and herring. When nets are placed for shad and herring and the fish are caught therein the eels often invade the net, and when it is drawn it is filled largely with the skeletons of the fish, the flesh of which has been removed by the eels. Eels have a high value as food fish, both on account of their nutritive value and their flavor. The average length of the eel is from 2 to 3 feet, though much larger examples are sometimes found.

Composition of the Eel.--

FRESH. DRY. Water, 71.60 percent Protein, 18.28 „ 65.25 percent Fat, 9.11 „ 31.92 „ Ash, 1.01 „ 3.60 „

These data show that the eel is rather richer in fat than the majority of fish, although there are some that exceed it in this constituent.

=Conger Eel.=--The conger eel belongs to the family Leptocephalidæ. It inhabits salt water only, is scaleless, and grows to much larger sizes than the common eel, sometimes as long as 7 or 8 feet. It is not used for food in the United States, but is to some extent in Europe and the West Indies. On the east coast of the United States they do not occur very frequently. Only a few species are known, and these are of small extent and have little food value.

=Summer Flounder.=--This fish (_Paralichthys dentatus_) is quite abundant on the Atlantic coast, frequenting the coast from Cape Cod to the Carolinas. It reaches a length of from 2 to 3 feet and has a weight of about 15 pounds. It is caught very extensively off the New England coast. The principal fishing grounds are in the region of Block Island, Marthas Vineyard, and the eastern end of Long Island. There is another species known as the southern flounder (_Paralichthys lethostigmus_), which flourishes from Charleston southward, and is found along the entire Gulf coast. There is also another species on the Gulf coast called the Gulf flounder (_Paralichthys albiguttus_). There is also a wide flounder or common flatfish (_Paralichthys americanus_). It is found on the coast of Labrador and extends down to the Carolinas. It is especially abundant along the coast of southern New England. It is a small species, rarely being over 20 inches in length, the average length being from 12 to 15 inches, and weighs from 2 to 3 pounds. This species of flounder has been extensively propagated by the U. S. Bureau of Fisheries, as many as 100,000,000 fry having been planted in one season.

Composition of Summer Flounder.--

FRESH. DRY. Water, 84.21 percent Protein, 13.82 „ 89.03 percent Fat, .69 „ 4.46 „ Ash, 1.28 „ 8.15 „

The flesh of this fish is particularly rich in water and poor in fat.

=Graylings.=--The graylings belong to a family very closely resembling the Salmonidæ. They occur chiefly in northern or Arctic waters. One species found in Michigan is known as the Michigan grayling. It is a fish that is not only distinguished on account of its food value but also on account of its graceful shape and pleasing appearance. Another species occurs in Montana, and has been distributed very largely by the Bureau of Fisheries. It is not a fish which is of any great economic importance.

=The Haddock.=--This is a fish very nearly related to the cod, but it has a smaller mouth and differs in other essentials, particularly in its chemical constituents, from the cod. The haddock has a food value which is probably not inferior to that of the cod. It is one of our most abundant fishes, and by some consumers the flesh is preferred to that of the cod. The usual weight of the haddock is about 3 or 4 pounds. It is, therefore, a much smaller fish than the cod. The species is _Melanogrammus æglefinus_. On the Atlantic coast it does not occur north of the Straits of Belle Isle. The haddock is particularly abundant on the Massachusetts coast in summer. Like the cod, the haddock is well suited for salting, smoking, and curing in various ways. It, however, has not been used to such an extent as the cod for those purposes, finding a more ready market in the fresh state.

Composition.--

Water, 81.69 percent Protein, 16.83 „ Fat, .25 „ Ash, 1.23 „

In the dry substance.

Protein, 93.89 percent Fat, 1.34 „ Ash, 6.76 „

The flesh of the haddock, it is seen, is even more exclusively nitrogenous than that of the cod. The two species resemble each other very closely in composition.

=The Hake.=--There are several species of hakes, family Merluccidæ. The common European hake is the species _Merluccius merluccius_. The hake which is found mostly in American waters is _Merluccius productus_, and occurs very abundantly on the Pacific coast and is largely eaten as food. The flesh, however, is rather coarse and not very palatable. Another species which is found on our Atlantic coast from New England northward is _Merluccius bilinearis_.

=Halibut.=--The halibut (_Hippoglossus hippoglossus_) is a fish which is highly esteemed and occurs in great quantities. It is a fish which frequents northern waters, and especially the North Atlantic on the American coast. It has not been taken south of Montauk Point, but extends as far north as the coast of Greenland, and is also found about Iceland and Spitzbergen in a latitude of 80 degrees. It does not like water above 45 degrees F., and is often found in water at the freezing point, namely, 32 degrees. The halibut is also found on the Pacific coast, especially off Oregon and Washington and in British Columbia and Alaska. It is one of the largest of food fish. The fish weighing about 80 pounds are considered the best for food, although the halibut sometimes reaches a weight of over 500 pounds. The male is always smaller than the female and less palatable. The annual value of the halibut fisheries on the North Atlantic coast is probably ¾■ million dollars. It is probably slightly more than this on the Pacific coast,--in fact the Pacific coast fisheries have grown so extensively that halibut is shipped eastward across the continent. Vast freight trains known as the “Halibut Express” have been sent across the continent from Vancouver to Boston, making the trip in six or seven days.

Composition.--

FRESH. DRY. Water, 75.42 percent Protein, 18.35 „ 77.18 percent Fat, 5.17 „ 19.32 „ Ash, 1.06 „ 4.39 „

The halibut is a fish containing considerable quantities of fat, and is not so peculiarly nitrogenous in its character as the cod or the haddock. It, therefore, makes a better balanced ration than either of the other fish. The halibut in the fresh state is esteemed fully as highly as the cod, and the halibut steak is a very common part of the fish sold upon the market.

=Herring.=--The herrings form a very important group of fishes belonging to the family Clupeidæ. There are about 30 genera in the family and 150 species. The herrings are essentially salt-water fishes and are usually found in large schools. Many species, and some of these the most valuable for food, ascend fresh-water streams for spawning. Certain species, for instance, are caught at the same season as the shad in the Chesapeake and Susquehanna. There are a few species which remain permanently in fresh water.

The common herring (_Clupea harengus_) is one of the most important of the food fishes of the whole Atlantic coast, and really over almost all the north Atlantic, throughout which it is generally distributed. The principal herring fisheries are in the North Sea, in Denmark and Norway. Important fisheries are also found off the coast of Great Britain, Belgium, France, and the United States. It is estimated that as many as three billion herring may be found in a shoal covering a dozen square miles. Herring shoals of much larger extent are on record. The herring do not frequent southern waters, but are found in the cool and more northern waters of the Atlantic. On the coast of the United States it has been found as far south as Cape Hatteras, though it does not occur very abundantly further south than New England. The fish at the period of spawning are considered the most valuable for food purposes.

The herring is either sold in a fresh state or it may be smoked, salted, or pickled, and in this condition is very extensively used as food. A species of herring is found on the Pacific coast known as California herring (_Clupea pallasii_). It does not differ very greatly in its general aspect from its relation on the Atlantic coast. This species occurs very abundantly in the region of Puget Sound, especially in summer time, and in southeast Alaska. They are extremely abundant in San Francisco markets in the spring time, so much so that it is difficult to find a sale for them.

The California herring are more highly valued and bring the highest price in the early winter, when they are the fattest.

Composition of Herring.--

FRESH. DRY. Water, 69.03 percent Protein, 18.46 „ 61.69 percent Fat, 11.01 „ 35.55 „ Ash, 1.50 „ 4.83 „

The above data show that the flesh of herring is particularly rich in fat. In fact the herring is sometimes used as a source of oil. In southeast Alaska are extensive oil and guano works which utilize the herring for these purposes.

=Horse Mackerel.=--Another species belonging to the mackerel family is the horse mackerel or tuna (_Thunnus thynnus_), which is found in considerable abundance on our North Atlantic coast and on the coast of southern California. Its common name is “tuna,” “tunny,” “horse mackerel,” or “great albacore.” The horse mackerel is a fish of very great size and is the very largest of the whole mackerel family. They occasionally attain a length of 10 feet or more and a weight of 1500 pounds. The average dimensions, of course, are very much less than this. The horse mackerel does not grow so large in Europe or upon the Pacific coast. In these regions a horse mackerel weighing 500 pounds is considered of an extraordinary size. The very large ones are never taken with hook and line, but there are records of fish of over 200 pounds that have been captured in this way.

=The Hogfish.=--The hogfish of the West Indies and our southern coasts is another of the wrasse-fishes whose scientific name is _Lachnolaimus maximus_. It is called in Porto Rico “el capitan.” It often reaches a weight of 20 pounds and a length of from 2 to 3 feet. The name “hogfish” doubtless is derived from the shape of the head, which resembles somewhat that of the hog. It is valued as a food fish throughout the West Indies.

=Lake Herring.=--The so-called lake herring is very closely related to the whitefish. The name of the species is _Argyrosomus artedi_. The lake herring has a large number of common names, of which the most widely applied is the term “Cisco.” The terms blueback, greenback, and grayback are also applied to these herring. The habitat of this fish is that of the whole region of the Great Lakes and north to Hudson Bay. It has much the same habitat as the whitefish. The average weight of the lake herring is about one pound. The subspecies (_Argyrosomus artedi sisco_) is found in Lake Tippecanoe and other small lakes in Wisconsin and northern Indiana.

Composition of Cisco.--

FRESH. DRY. Water, 76.15 percent Protein, 19.12 „ 80.75 percent Fat, 3.48 „ 14.59 „ Ash, 1.25 „ 5.25 „

=Mackerel.=--The mackerel is a food fish which is very commonly used in a cured state in the interior of the country and is eaten fresh on the sea coast. Its habitat is principally the North Atlantic ocean. On the coast of the United States it is found from Cape Hatteras north to the Strait of Belle Isle. In Europe it is found from Norway southward to the Mediterranean and Adriatic. The mackerel on the Atlantic coast usually appear first in the spring near Cape Hatteras and following the custom of the shad are found later farther north in the New England states and also in the British possessions. They leave the coast in the inverse order in the autumn, disappearing first in the northern regions and later in the southern portion.

The mackerel is one of the most abundant of fishes in the Atlantic Ocean, traveling in immense schools. There is record of a school which was seen in 1848 which was at least half a mile wide and 20 miles long. In some seasons the mackerel is extremely abundant and in others very scarce. The average catch is probably about 300,000 barrels. Boston and Gloucester are centers of the mackerel fishing industry. It is estimated that from 150 to 300 vessels of American bottoms are engaged in the mackerel industry. The U. S. Bureau of Fisheries has been particularly interested in the propagation of mackerel, but the result has not been as satisfactory as in the case of many other fishes. The young mackerel or small fishes are known as “spikes,” “blinkers,” and “tinkers.” When they are about two years old they measure from 5 to 9 inches in length. The mackerel attains its full size at about the fourth year. The scientific name of the common mackerel is _Scomber scombrus_ Linnæus.

Composition of Mackerel.--Edible portion:

FRESH. DRY. Water, 73.37 percent Protein, 18.26 „ 71.71 percent Fat, 7.09 „ 24.88 „ Ash, 1.28 „ 4.78 „

The above data show that the flesh of the mackerel is composed of about two-thirds protein and one-third fat and ash.

Pickled mackerel, salted mackerel, and smoked mackerel are perhaps as highly valued for food purposes as the fresh fish itself.

=Menhaden.=--The menhaden is not used chiefly as a food fish but to some extent therefor. It is one of the most abundant fishes taken upon our Atlantic coast and is used almost exclusively as a source of oil, the residue being dried and ground for fertilizing purposes. In this sense it has great value because of the high nitrogen content of the residue and also of the considerable quantity of phosphoric acid which is contained therein.

The menhaden is known scientifically as _Brevoortia tyrannus_. Up to 1880 immense quantities of menhaden were taken off the Atlantic coast. Since that time the supply has not been considered so great. In the year 1877 it is stated by Jordan and Evermann that one oil company took 20 million fish and in one town alone, namely Booth Bay, 50 million fish were caught.

The fecundity of the menhaden is very great, exceeding that of the shad. More than 140,000 eggs have been taken from a single fish. The menhaden are not eaten very extensively in a fresh state as food but preserved in salt they have a considerable value for that purpose. An extract has also been made from the flesh of the menhaden on the same principle of manufacture as is utilized in preparation of meat extracts. The menhaden is known under a great number of common names, some thirty of which have been enumerated by Dr. Goode.

Composition of Menhaden.--

Water, 77.15 percent Fat, 3.91 „ Protein by difference, 18.94 „

The water-free flesh contains (including bones) 21.7 percent of mineral matter.

Composition of the Mineral Matter.--

Lime, 8.67 percent Phosphoric acid, 7.78 „ Silicic acid, 1.33 „ Potash, 1.54 „ Soda, 1.02 „ Magnesia, 0.67 „ Chlorin, 0.69 „ ----- Total, 21.70 „

=Mullet.=--The mullet belongs to the Mugilidæ, an important family of fishes in which there are several genera and species. The mullet is not particular about its food but is in the habit of swallowing large quantities of mud, or rather partially swallowing it and separating the refuse and most obnoxious particles by means of the gills. The common mullet or striped mullet (_Mugil cephalus_) is a widely distributed species. This fish is common along the Atlantic coast and in Hawaii, usually traveling in large schools, and is most abundant in the shallow waters of the coast. It sometimes reaches a length of two feet and is an important food fish. The mullet is very abundant on the Florida coasts. While the mullet may be regarded as a scavenger, living principally on mud, it does not eat any other species of fish, but is itself eaten by nearly all fishes that can gain access to it.

Composition of the Mullet.--

FRESH. DRY. Water, 74.87 percent Protein, 19.32 „ 77.50 percent Fat, 4.64 „ 18.45 „ Ash, 1.17 „ 4.66 „

=Muskallunge.=--A very noted member of this family is the muskallunge (_Esox masquinongy_). It is a native of the Great Lakes and is especially found in the upper St. Lawrence. It is not a very abundant fish, but is highly prized from the angler’s point of view.

It is of very great size, having been found as long as 8 feet and weighing over 100 pounds. Two other species of muskallunge are known, one (_Esox ohiensis_ or the Chautauqua muskallunge) in the Ohio river basin, particularly in Lake Chautauqua, where it has been artificially propagated with great success, and the unspotted muskallunge (_Esox immaculatus_), which occurs sparingly in certain small lakes of northern Wisconsin and Minnesota.

Composition of the Muskallunge.--

FRESH. DRY. Water, 76.26 percent Protein, 19.63 „ 84.87 percent Fat, 2.54 „ 10.70 „ Ash, 1.57 „ 6.63 „

The flesh of the muskallunge, as is seen, contains about four times as much fat as that of the pickerel, and forms a ration which is not so unbalanced as that of the pickerel itself.

=Pickerel or Pike.=--One species (_Esox reticulatus_) is of common occurrence along the Atlantic coast and also in the fresh-water streams of the southern interior portions of the country. The pike of the Great Lakes belongs to the species _Esox lucius_ Linnæus. It is found in the fresh waters of North America, Europe, and Asia, but is not found on the Pacific coast except in Alaska. It reaches in some cases a large size, having been found as much as 4 feet in length and weighing 40 to 50 pounds. The Kankakee in northern Indiana is a well-known fishing ground for this species of pike.

Composition of Pickerel.--Edible portion:

FRESH. DRY. Water, 79.68 percent Protein, 18.64 „ 92.15 percent Fat, .50 „ 2.48 „ Ash, 1.18 „ 5.80 „

The flesh of the pickerel, as is seen, is almost a pure type of protein. The fat falls to an insignificant quantity, being only about half as much as the ash.

=Wall-eyed Pike.=--The wall-eyed pike or pike perch (_Stizostedion vitreum_) is a fish most abundant in Lake Champlain, the Great Lakes, and in eastern Canadian lakes; it occurs also in certain small lakes and streams in the upper Mississippi valley. In some localities it is known as the salmon or jack salmon, but of course these are misnomers.

Composition.--

FRESH. DRY. Water, 75.71 percent Protein, 19.03 „ 79.31 percent Fat, 4.07 „ 16.74 „ Ash, 1.19 „ 4.92 „

=Common Pompano.=--The pompano (family Carangidæ) is one of the food fishes which is most highly esteemed along the Gulf coast. It has been found as far north as Cape Cod on the Atlantic coast, but does not occur in sufficient numbers to make it of any economic value as a food fish north of Florida. It is taken chiefly in the Gulf waters. The average weight of the pompano is from 2 to 3 pounds, though very much larger examples are sometimes found. As a food fish there is none that is regarded more highly than the pompano, especially when it is eaten fresh from the water and prepared in the manner of the creole cooks of New Orleans.

Composition.--

FRESH. DRY. Water, 72.78 percent Protein, 18.65 „ 72.37 percent Fat, 7.57 „ 24.46 „ Ash, 1.00 „ 3.82 „

These data show that the edible portion of the pompano is valued both for its protein and its fat. The latter exists in quantities of approximately one-third of the former. It is not so much its nutritive value which makes the pompano desirable as a food fish but the extreme delicacy of flavor and the richness of its taste. It does not bear shipping well, and therefore is found in its greatest perfection only near the place where it is taken.

In New Orleans and in Florida the pompano is one of the principal food fishes furnished by the high-class hotels and restaurants to their guests.

=Red Snapper.=--The red snapper (_Lutianus aya_) is the most noted fish of all the snapper family (Lutianidæ), although there are others which are highly prized, such as the gray snapper. It sometimes reaches a length of two or three feet and a weight of from 10 to 35 pounds. It is particularly abundant in the deep waters of the Gulf of Mexico and off the west coast of Florida. The red snapper bears shipping better than most of the Gulf fish, and Pensacola is one of the principal points where the fish are packed in ice as soon as possible after capture and dispatched to northern markets.

Composition.--

FRESH. DRY. Water, 78.46 percent Protein, 19.20 „ 91.75 percent Fat, 1.03 „ 4.70 „ Ash, 1.31 „ 6.05 „

This is another one of the fishes in which the edible portion is almost exclusively protein, the fat appearing only in small quantities.

=Rock Bass=; =Redeye=; =Goggle-eye= (_Ambloplites rupestris_).--The rock bass is a very common fish particularly abundant in the fresh waters of the northern central portions of the United States. It is the fish which the American boy, living near small streams, most delights to catch. The size of the rock bass varies largely according to the magnitude of the body of water in which it lives. The average weight of the fish in streams of ordinary size is probably about a pound, though often it is considerably more. The rock bass has been propagated to some extent by the Bureau of Fisheries and has been introduced into waters where it formerly did not occur.

=Salmon.=--The salmon is one of the most important food fishes of the United States. It belongs to the genus _Oncorhynchus_. The five species of this genus are, in America, confined to our Pacific coast. Of these species the one known as blueback or sockeye is found most abundantly in the Fraser and Columbia rivers and in Alaska, the silver salmon in Puget Sound, the chinook salmon in the Columbia, and the dog salmon along the coast from California to Bering Sea. The salmon begin running early in the spring and the early run is considered of greater value than the later. The habits of the salmon in the deep waters of the ocean are not very well known. It is only when they come into fresh water for spawning purposes that their life history can be well studied. It is believed, however, that they do not go very far from the shore. The run of salmon on the Pacific coast usually begins about the latter part of March and lasts through the spring and greater part of the summer. On account of the great abundance of these fish on the Pacific coast and the distance from large markets the canning industry has developed with great rapidity. In fact on the Pacific coast the product of salmon fishing is devoted almost exclusively to canning purposes. In the canning of salmon no particular care is taken, and perhaps none at all to designate upon the can whether its contents are of the early salmon or the later, less valuable run. It is claimed by many authorities that the salmon of the Pacific coast of America, taken all together in their relation to the economic problem of fish food, are the most important and valuable fish in the world.

Composition of a Pacific Coast Species.--

FRESH. DRY. Water, 63.61 percent Protein, 17.46 „ 52.31 percent Fat, 17.87 „ 49.05 „ Ash, 1.06 „ 2.92 „

Composition of Atlantic Salmon.--

FRESH. DRY. Water, 63.61 percent Protein, 21.60 „ 61.45 percent Fat, 13.38 „ 36.88 „ Ash, 1.41 „ 3.81 „

The above data show that the Pacific salmon are richer in fat than the Atlantic salmon. In fact in the edible portion of the fish the fat is almost as great as the protein.

Another species of Pacific salmon is the humpback salmon (_Oncorhynchus gorbuscha_), which appears in great abundance in the rivers of Alaska, but not every year,--usually coming in larger quantities in alternating years. As a fish to be eaten fresh, this is one of the very best of the salmons. Owing to the pale color of the flesh, this species does not hold as high a rank for canning purposes. It cans well, however, and the product is very palatable and doubtless very nutritious. The trade-name of the canned product is “pink salmon,” as its flesh is of a paler color than that of the chinook salmon or red salmon. Another species is known as dog salmon. It is found in considerable abundance from California northward to Bering Strait, spawning usually late in the fall. It is considered as the least valuable for food purposes, although it is now coming to be used very extensively by freezing, in which form it finds a ready market both in this country and abroad. When canned it is put on the market as “chum.” Its chief interest at the present time is on account of the fact that it is sometimes sold under the names of better species.

=Chinook Salmon= (_Oncorhynchus tschawytscha_).--This species is also known as quinnat, king, Columbia river, and Sacramento river salmon. It is, next to the sockeye, the most important of all salmon in commercial value. The individuals of this species reach a larger size than those of any other. They have been known to weigh 90 pounds, and fish of from 40 to 60 pounds in weight are not infrequently taken. The average weight of the king salmon which are captured in the Columbia river is probably not far from 22 pounds, while those that run further south, for instance in the Sacramento river, average 16 pounds.

Another species, known as silver salmon (_Oncorhynchus kisutch_), also has a number of other names, mostly of Eastern or Russian origin. It is quite an important member of the genus and its average weight is about 5 pounds. It is very valuable as a food

fish, only the Chinook and blueback salmon going ahead of it. It is also a species which bears shipment in a fresh state very well. The silver salmon resembles very closely the Chinook, but is easily distinguished therefrom by experienced fishermen. The canned product of this species is usually put on the market as “medium red” or “coho” salmon, names which have now come to have a definite meaning and are perfectly understood by the trade.

=The Sockeye or Blueback Salmon= (_Oncorhynchus nerka_).--This is the species which has the greatest commercial value and forms a large part of the catch of the Pacific coast. It is the most abundant of all the species of salmon in Alaska. Its flesh has a rich red or “salmon” color, and lends itself admirably to canning processes. In palatability and attractiveness as a canned product it is not inferior to any, unless, possibly, the Columbia river chinook.

Canning of Salmon.--The canning of salmon is one of the most important of the fish industries of the United States. The immense coast line possessed by the United States on the west, which is so vastly extended by the Alaskan coast and Aleutian Islands, affords the most extensive fisheries of salmon in the world. As has already been stated, there are no large markets in that region in which the fresh salmon can find a purchaser. The fish, therefore, must be neglected as a food product or else prepared in some way to enable them to be shipped to great distances. Probably the most unobjectionable way is by canning. The principles of the canning of salmon are not different at all from those which underlie the sterilization of any kind of food. The establishments in which the canning takes place are perhaps the most extensive in the world. The prime necessity in these cases is to secure complete sterilization. In the case of fish any failure to secure the proper sterilization is the more reprehensible, because fish decompose so readily, forming fermentative products which are extremely poisonous. Cases of poisoning from eating canned salmon have been reported, and in some cases they may prove fatal. Every can of salmon which is to be eaten ought to be examined carefully in order to see if there are any incipient signs of decomposition. A bad smelling or otherwise imperfect can should be rejected without question. Only the fish which is perfectly fresh to the taste and odor and which gives no signs of any kind of deterioration should be eaten. When properly prepared, canned salmon affords a delicacy as well as a food product which can hardly be too highly prized.

Composition of Canned Salmon.--Mean of three samples. Water-free substance:

Protein, 53.52 percent Fat, 40.52 „ Ash, 6.24 „

=The Salmon of the Atlantic Coast.=--As has already been noted, the Pacific salmon belong to a different genus from the common Atlantic salmon,--_Salmo salar_. There is a very close resemblance between the two genera, and the common name “salmon” is applied to the individuals of each. The Atlantic salmon is a fish which has been known from the earliest time. The Roman people became acquainted with it in the early history of the Republic, and especially when they conquered Gaul and Britain. It is found distributed over the whole North Atlantic coast, but especially the northern portion from Massachusetts northward. The salmon extends, as far as observations have been made, beyond even the Arctic circle, and the same species is found upon the western and northern shores of Europe. The salmon enters the St. Lawrence and has been found as far up as Niagara Falls. Our principal fisheries for this species are in Maine and in Canada, Nova Scotia, and New Brunswick. They do not extend southward beyond the Delaware and have rarely been found in that river. The shad and salmon were particularly abundant in early colonial days. The shad were so abundant that they were not regarded as useful for food purposes, but their value as a fertilizer was taught to the whites by the Indians. Salmon, apparently, were equally abundant, and it was considered an affront to offer salmon more than twice a week even to servants. In this respect they were on the same plane as the diamond back terrapin and canvas back duck, which were so abundant, in those days, that they were a drug on the market. The salmon enters the fresh-water streams for the purpose of spawning. The eggs are largely laid late in the fall, and in that case do not hatch until the next spring. The Atlantic salmon often reach a very large size. Individuals have been known to weigh from 40 to even 80 pounds. The average weight of the salmon taken in Maine waters is about 10 pounds each. Another valued specimen of salmon is known as the Sebago salmon (_Salmo sebago_), from the lake in which it occurs. It is a fresh-water fish, having been doubtless landlocked in some way after originally entering from the sea. Still a third species is the famous ouananiche (_Salmo ouananiche_), inhabiting the waters of the Lake St. John region north of Quebec.

Composition of Atlantic Salmon.--

FRESH. DRY. Water, 76.74 percent Protein, 18.52 „ 79.13 percent Fat, 3.60 „ 15.32 „ Ash, 1.14 „ 4.93 „

Composition of Sebago Salmon.--

FRESH. DRY. Water, 78.54 percent Protein, 17.24 „ 78.00 percent Fat, 2.98 „ 13.74 „ Ash, 1.24 „ 5.76 „

The above data show a striking difference in the composition of the edible portions of Pacific and Atlantic salmon. This difference is shown chiefly in the relative proportion of fat. In the Pacific salmon the fat approaches in quantity the protein, while in the Atlantic salmon the protein is much greater than the fat. The Atlantic salmon is used chiefly in the fresh state for two reasons, first, because the catch is very much smaller than that of the Pacific species while the markets are very much more numerous and very much larger; second, because it is commercially more profitable to dealers in the fresh state. In Europe and Scotland the salmon is constantly used in a fresh state during the whole of the summer and a dinner is scarcely considered complete without it. It is also very commonly used at luncheon. It is generally eaten cold and offers a food product of high palatability and great nutritive value in so far as the protein is concerned. Eaten with plenty of potato, as it usually is, it forms a reasonably well-balanced ration. The American visitor who is not used to eating salmon every day is likely to find its constant occurrence upon the English table in the summer to be a bit trying to his taste.

=Sardines.=--The sardine belongs to the herring family--in fact small herring along the coast of Maine are put up as sardines. The sardines are very closely related to the herrings, but there are rather important differences. The European sardine, which is known as the sardine, is the _Sardinia pilcharda_, and does not occur on the coast of the United States. The species existing on the Pacific coast is known as the California sardine (_Sardinia cærulea_). It is quite abundant on the California coast and spawns in the open sea. It resembles very strongly the European sardine, but has no teeth. The Spanish sardine (_Sardinia pseudohispanica_) is found rather abundantly in Cuba and is often carried northward in the Gulf Stream as far as Woods Hole or Cape Cod. It is about 8 inches in length and of high food value, resembling very closely the European sardine. There has been a good deal of discussion as to whether or not small herring which are packed as sardines in the United States should be allowed, under the food laws of the various states and of the United States, to be sold by that name. The answer to this is that any deception in the label should be avoided. The herring, however, belongs to the same genus as the true sardine, and, differing from it only in the variation of species, may have some right to the name. The true ethical principles of trade, however, would require that they should be named Maine sardines or herring sardines and not bear the name simply sardines, which is reserved exclusively for the species _Sardinia pilcharda_.

Composition of Canned Sardines.--

Water, 56.37 percent Water-free substance, 43.63 „ Protein, 24.87 „ Fats, 12.71 „ Ash, 5.00 „ Sodium chlorid, 0.61 „

The above data are based upon the analysis of the sample after the oil has been separated by drainage.

=European Sardines.=--The sardine is eaten fresh along the Spanish and French coast, where they are taken in great abundance and form a delicious food in this condition. The number which is given to a single individual is quite generous, as the writer has had served him on the Mediterranean coast in Spain as many as twenty fresh sardines at one order. The number, however, was not found any too large when the palatability of the product is taken into consideration. Sardines are preserved by salt and smoke and particularly by packing in oil.

Method of Packing in Oil.--The sardines after proper cleaning are heated in oil for the purpose of sterilizing them. Olive oil is usually employed for this purpose, though some packers prefer to heat the fish in peanut oil, claiming that it gives them a better color. There seems to be, however, no sufficient ground for this claim. The peanut oil is probably used simply because it is cheaper. When the fish are thus sterilized and thoroughly cooked they are placed in boxes in the well known manner in which they are found and covered with oil, sealed, and, if necessary, again sterilized in order to prevent decomposition. Olive oil is the oil usually employed for packing purposes, though cheaper grades of edible oil are very commonly found in sardines. The substitutes for olive oils which are usually employed are peanut oil, cottonseed oil, and sesame oil, either single or mixed. When the sardines have been previously boiled in a cheaper oil and then packed with olive oil the olive oil will be contaminated with the cheaper oil used in the boiling.

Adulteration of Sardines.--As indicated above, the chief adulteration of sardines is in the misbranding respecting the nature of the fish and the oil used in packing. A young herring packed in the manner of a sardine properly demands a special label instead of the word “sardine” alone. A difference respecting the misbranding in regard to the oil employed is avoided by the statement on the package of the character of the oil used. The phrase “Sardines packed in oil” should be construed always to mean in the highest grade oil, that is, olive oil. This phrase, however, is usually employed when inferior oils are used. Inasmuch as oil is not the name of

any individual product but of a large class of products, including that of both animal and vegetable origin, it is generally held that the term “oil” is not a sufficient indication of the character of the oil used. In all cases the packages should designate the special kind of oil used in the preparation. The addition of chemical preservatives to sardines in so far as the author knows, is not practiced, at least not to any appreciable extent.

The French Fisheries.--The sardine fisheries in France are mostly off the coast of Brittany, and are subject to many very serious fluctuations. For instance, the present year, 1906, has been one of disaster to the French fisheries. What is the cause of the disappearance of the pilchard (the true sardine) is not known. The fishermen think that large fish have driven the small ones either into the Bay of Biscay or the Mediterranean, or even to the west shores of Africa. The fish are thought to originate in the Mediterranean, and their name is derived from the fact that they were originally found in great quantities off the coast of Sardinia. When the spring comes and the fine weather is established they migrate first along the coast of Spain, finally reaching the French coast some time during the month of May. By this time the young fish are nearly grown to a proper size for catching. The fishing, however, does not really begin until July and is usually finished by November. The little town of Concarneau is the seat of these fisheries. About two thousand small boats go out from this town and at or near this place are also the large canneries and packing establishments. The fishing grounds are about five miles from the coast and the small boats sail out from two to four o’clock in the morning. The fishing is by means of nets and a very important part of the work is the spreading of the bait upon the surface of the water to attract the fish. The principal bait or _roque_ is the roe of the cod, which sometimes reaches a price of $60 per barrel. Sometimes a single boat will use from 30 to 40 barrels of bait. Only the most skilled fisherman, usually the master himself, is allowed to distribute this precious material. As many as one hundred thousand fish have been caught in the net, though this magnitude of catch is, of course, exceptional. When the fish are brought ashore they are counted into baskets, about 200 to a basket, and those unfit for use are thrown out. They are taken to the canneries as quickly as possible to be cleaned, boiled, dipped in oil, and then hermetically sealed into a tin in which they are sent into commerce.

Adulteration.--The chief adulteration of sardines is found in misbranding as to country of origin. The French catch has the highest reputation of any in the world and for this reason the label is often made to represent the fish as of French origin when in reality they are caught on the shores of Spain or of other countries. Formerly the fish were brought in great numbers from the Spanish coast into France. They were naturally much deteriorated in transit. Nevertheless they were tinned and marked as of pure French origin. This practice has now been forbidden by law in France. The Norwegian fish known as Sprötten (sprats) on the German and Holland coasts are packed as sardines and sent into this country as sardines.

=Scup.=--The scup is a fish (family Sparidæ) which is taken in great abundance on our Atlantic coast in the summer and autumn and is brought in immense quantities to the market. The proper name of the fish is _Stenotomus chrysops_.

Composition.--

FRESH. DRY. Water, 74.99 percent Protein, 18.52 „ 75.33 percent Fat, 5.11 „ 19.25 „ Ash, 1.38 „ 5.64 „

The flesh of this fish is a better balanced ration than that of the red snapper, the proportion of fat being much larger.

=Shad.=--One of the most important food fishes on the Atlantic coast is the shad. It is found along the whole Atlantic coast, coming into fresh water for spawning, where it is caught for food purposes. The shad begin to appear in the streams of the south Atlantic coast early in the winter and as the spring advances they go northward. They appear in the Potomac in April and May, and later in the Delaware and Connecticut rivers and other fresh-water streams further north. The fish is, therefore, to be had fresh upon the market over a long period of time. The common shad is known scientifically as _Alosa sapidissima_ (Wilson). As a result of the work of the U. S. Bureau of Fisheries the shad has been introduced into the waters of the Pacific coast where none was found originally. The shad fry were first introduced into the Sacramento river and afterward into the Columbia river. The environments on the Pacific coast were found congenial. The fish soon found grounds on which they could spawn, and they have spread over almost the entire length of the Pacific coast. It has, of late, become a very common and abundant food fish on the Pacific coast and has lost none of its palatability by transplanting. Science has not been able to ascertain anything of very great interest respecting the life of the shad in the sea. When they leave the rivers they practically disappear, and are not known again until the next spawning season returns. For spawning purposes the shad prefer a water temperature of from 55 to 65 degrees. Whenever the temperature goes above the latter figure they begin to disappear. The males and females go in separate schools. The males usually precede the females. It is stated by Jordan and Evermann that of 61,000 shad received at the Washington market from March 19 to 24, 99

percent were male. As the season advanced the males became very much less frequent and at the end extremely scarce. The U. S. Bureau of Fisheries has taken especial pains to increase the number of shad in all waters. During the spring of 1900 there were artificially planted in the Atlantic coast streams over 240,000,000 young shad. One fish often contains as many as 150,000 eggs. The average number, however, is about 30,000. Shad roe is the most valuable part of the fish and brings a much higher price in the market than an equal weight of fish itself. Planked shad is one of the greatest delicacies of the Washington markets. At Marshall Hall, opposite Mount Vernon, there are given a great many shad bakes during the season. Oak wood is placed in long lines and burned,--oak planks are set up on each side of the line of burning wood, inclined at an angle of about 60 or 70 degrees. On these oak planks the shad are cooked, held usually by driving a nail through the head,--the cut surface being exposed to the heat of the burning fire. In addition to being cooked in this way the fish absorbs a small amount of the empyreumatic odors of the burning wood. During the baking the shad are treated from time to time with melted butter. There is no other way which a shad can be cooked which renders it so delicious as by this primitive method. The shad, from an economic point of view, is third in importance in the United States, only the salmon and the cod exceeding it in value. The annual catch of shad on the Atlantic sea coast numbers from 10 to 20 million, weighing from 40 to 60 million pounds and worth from one and one-half to two million dollars.

Composition of Shad.--

FRESH. DRY. Water, 70.62 percent Protein, 18.56 „ 64.36 percent Fat, 9.47 „ 31.93 „ Ash, 1.35 „ 4.62 „

Of the whole weight of shad the average edible portion amounts to 52.35 percent, and the refuse, counting the bones, skin, and entrails is 47.65 percent.

Shad Roe.--The eggs of shad, as has already been mentioned, are regarded as the most valuable portion of the fish. Roe shad also are more highly prized as a food fish than the male shad. As a result, roe shad sell for a much higher price on the market than the male shad. The eggs are quite small, and as has already been said, occur in immense numbers, the average number to a fish being about 30,000.

Composition of Shad Roe.--

Water, 71.2 percent Protein, 23.4 „ Fat, 3.8 „ Ash, 1.6 „

Aside from the water of the roe, it is noticed that by far the most abundant component is the protein. This, of course, is what would be expected of an egg product. The protein is a little more than six times as great as the fat. The ash contains large quantities of phosphorus, which exists in the original egg, largely in the form of lecithin, in which state it is regarded as most valuable for nourishing the phosphatic tissues of the body. Shad roe is eaten almost entirely in the fresh state. It does not produce a pickled or cooked product of anything like the value of the sturgeon eggs. So far as the author knows no form of shad egg preparation similar to caviar is on the market.

There are three species of shad in America, but the only one of great importance is the common Atlantic shad which has been described.

=The Sheepshead.=--This abundant and important food fish exists in large numbers along the Atlantic coast. It also belongs to the Sparidæ and its scientific name is _Archosargus probatocephalus_. This species is found from Cape Cod to Texas. It is especially found in the vicinity of oyster beds, where it is destructive to the oysters. It is quite abundant in the Indian river, being, next to the mullet, the most frequently found fish in those waters. Though strictly a salt-water fish, it often runs up into fresh waters. The fish is distinguished by the number of broad silvery colored bands extending around its entire body. The average weight of the sheepshead is three or four pounds, though occasionally a fish three or four times that size is captured.

Composition of Sheepshead.--

FRESH. DRY. Water, 75.55 percent Protein, 19.54 „ 83.47 percent Fat, 3.69 „ 13.59 „ Ash, 1.22 „ 5.14 „

=The Smelt.=--The smelt belongs to a family which has a number of species, some of which are very abundant in Europe, where they are highly prized even to a greater extent than in this country for food. The smelt is a small fish, very long in proportion to its breadth. The American smelt (_Osmerus mordax_) is found very abundantly on the Atlantic coast north of New York. Although a sea fish, it often enters rivers and becomes landlocked in lakes. It is found abundantly in Lakes Champlain and Memphremagog

and many of the New England and Nova Scotian lakes. The smelt in early times was a very abundant fish.

Composition of the Smelt.--Edible portion:

FRESH. DRY. Water, 79.16 percent Protein, 17.37 „ 84.31 percent Fat, 1.79 „ 8.65 „ Ash, 1.68 „ 8.16 „

These data show that the flesh of the smelt is very rich in protein, the fat falling to a very small proportion of the total edible substance.

=Spanish Mackerel.=--This is a very highly prized fish and is eaten largely in the fresh state along the Atlantic coast. Its scientific name is _Scomberomorus maculatus_. The catch is subject to great variations. In early years the Spanish mackerel was scarcely known on our coast, but in the last forty years it has assumed considerable importance. Although more abundant than formerly it still commands a very high price. The weight of the full-grown mackerel is usually from five to eight pounds, though occasionally very large individuals are taken. Jordan and Evermann speak of one which was 41 inches long and weighed 25 pounds.

Composition.--Edible portion:

FRESH. DRY. Water, 68.10 percent Protein, 20.97 „ 67.25 percent Fat, 9.43 „ 29.56 „ Ash, 1.50 „ 4.71 „

In this fish it is seen that the fat is a little less than one-third the quantity of the protein.

=Sturgeon.=--The sturgeon belongs to the family of Acipenseridæ. They are large fishes frequenting the sea and also the fresh waters of northern regions. Most of the species are anadromous, entering fresh water and ascending the streams in spring. There are two genera belonging to this family and 20 species that are well defined, although about 100 nominal species have been described. The white sturgeon or Oregon sturgeon is found on the Pacific coast from Monterey north to Alaska. It ascends the large rivers during the spring, notably the Sacramento, Columbia, and Fraser rivers. Some of them are very large and their value for food and commercial purposes has only been lately recognized. They are principally valuable, however, for their eggs or roe, since it is from the eggs of sturgeon that caviar is made. The roe in the fresh state is worth from 25 to 30 cents a pound. The fresh fish are frozen and shipped to Eastern markets.

The common sturgeon (_Acipenser sturio_) frequents the east and north Atlantic coast and ascends the rivers in the spring, especially the Delaware. The quantity of sturgeon taken, however, has constantly decreased for several years. The principal part of the caviar made in the United States is procured from the common sturgeon and the Lake sturgeon, which is found in the Great Lakes, the upper Mississippi Valley, and the Lake of the Woods.

Preparation of Caviar.--After the eggs have been removed from the fish, they are placed in large masses upon a stand, the top of which is formed of a small-meshed screen. On the under side is placed a zinc-lined trough, about 18 inches deep, 2 feet wide and 4 feet long. The operator gently rubs the mass of eggs back and forth over the screen, whose mesh is just large enough to let the eggs drop through as they are separated from the enveloping membrane. They thus fall into the trough from which they are drawn off into tubs through a sliding door in one end of the trough. After all the roe has been separated, the tub is removed and a certain proportion of the best Luneberg salt is added and mixed with the eggs by careful stirring with the hands. This is the most delicate part of the whole process, and the best results can be obtained by that proficiency which comes from long experience. After adding the salt, the eggs at first become dry, but in 10 or 15 minutes the salt has drawn from the eggs their watery constituents and a copious brine is formed, which is poured off when the tub becomes too full. The salted eggs are then poured into fine-meshed sieves which hold about 10 pounds each, where they are allowed to drain for 8 to 20 hours. The eggs have now become the caviar of commerce, which is put in casks or cans of various sizes.

Composition of the Flesh of Sturgeon.--

FRESH. DRY. Water, 78.71 percent Protein, 17.96 „ 85.19 percent Fat, 1.90 „ 8.90 „ Ash, 1.43 „ 6.72 „

Composition of Caviar.--

Water, 66.05 percent Protein, 14.37 „ Fat, 8.97 „ Ash, 7.26 „ Undetermined, 3.35 „

Of the ash, 6.16 parts of the 7.26 present are common salt.

=Composition of the Eggs of Fish.=--Attention has been called to the valuable food properties of the eggs of fishes. The roe of a number of fishes is celebrated both for flavor and food value. The two most important roes are those of the sturgeon, used in the manufacture of caviar, and the roe of shad, used principally in the fresh state.

=Composition of Roe.=--The composition of shad roe, fresh sturgeon caviar, and pickled caviar is given in the following table:

---------+---------+---------+---------+--------- | WATER. | PROTEIN.| FAT. | ASH. ---------+---------+---------+---------+--------- |_Percent_|_Percent_|_Percent_|_Percent_ Shad roe, | 71.25 | 23.44 | 3.78 | 1.53 Fresh caviar, | 56.97 | 27.87 | 2.85 | 2.31 Pickled caviar,| 50.92 | 27.92 | 13.59 | 7.57 ---------+---------+---------+---------+---------

The above data show a marked difference between the composition of shad roe and sturgeon roe, the latter being very much richer in fat and also containing a greater quantity of ash. The large quantity of ash in the pickled caviar is doubtless due to the common salt used in the curing. There is not a very great difference between the composition of the roe and that of the flesh of fish. The roe is essentially a nitrogenous food, also with a considerable quantity of fat and with a certain amount of mineral matter. It contains less water than the flesh of fish, and, therefore, pound for pound in the fresh state has a larger quantity of nutrients. Otherwise, for food purposes, there is but little difference. It is doubtless true, however, that the mineral matters of the roe are somewhat different from those of the flesh of fish in containing a larger quantity of organic phosphorus in the form of lecithin.

=Striped Bass.=--The striped bass or rock (_Roccus lineatus_) is a fish of the family Serranidæ and quite common in the Potomac. It occurs commonly around the Atlantic coast. Its scientific name is _Roccus lineatus_. It is taken in all waters along the coast from the Carolinas to New England, and especially near the mouth of the Potomac and in Chesapeake Bay. It is a fairly common as well as one of the best food fishes at Washington and in many of the fish markets on the Atlantic coast.

FRESH. DRY. Water, 77.70 percent Protein, 18.31 „ 83.28 percent Fat, 2.83 „ 12.50 „ Ash, 1.16 „ 5.22 „

=Sole.=--The term “sole” is applied here to certain species of flounders and the two terms are sometimes used synonymously. The true soles, however, of which there are several species, belong to a distinct though closely related family. The species of flounder to which the term “sole” is generally given is _Eopsetta jordani_. It occurs along the Pacific coast from Monterey to Puget Sound. Large numbers are taken in Monterey Bay. The average weight of this “sole” is about three pounds. It is highly esteemed as a food fish. They are dried in great numbers by the Chinese, who suspend them by strings on a frame placed on the roofs of the houses, where, after they become dry, they strike against each other when moved by the wind, producing a sound which is something like that emanating from the leaves of a forest.

=Tautog.=--The _Tautoga onitis_ is one of the wrasse-fishes (family Labridæ) and is abundant along the Atlantic coast from New Brunswick to the Carolinas. East of New York it is commonly called the “tautog.” On the New York coast it is known as “blackfish,” and further south as the “oyster fish.”

=Tilefish.=--The tilefish is interesting not because of its high food value but because of the fact that it was discovered by accident in 1879 when a fisherman off the coast of Nantucket captured 5000 pounds of a fish which was new to him. The species was also new to science. This fish disappeared as suddenly as it came and no more were caught until 1892. Since then they have been taken rather frequently. The tilefish reaches a length sometimes of three feet and a weight of 30 pounds. It is pronounced by experts to be the equal of the pompano.

=Trout.=--Trout, of which there are many species, are greatly prized both on account of their value as game fishes, affording sport for anglers, and because of their high palatable qualities. They belong to the same family as the Atlantic salmon and often it is difficult to distinguish by any of its common characteristics a trout from a salmon. This is especially true of trout of western America. The species of trout which are most highly prized on the Pacific coast are the cut-throat trout (_Salmo clarkii_), the rainbow trout (_Salmo iridens_), and the steel-head (_Salmo gairdneri_). The familiar silver trout of Lake Tahoe is another closely related species. They are distinguished by a remarkable system of spots of a circular form, black in color, and of varying size. The Lake Tahoe trout which is commonly secured is not the same as the silver trout of Lake Tahoe but is of a little different character, and is also known as the Truckee Trout, “Pogy,” and “Snipe.” It reaches a weight of from three to six pounds and is sometimes served on the dining cars of the Central Pacific Railway, in running through Idaho and into California. Various other species of the trout are found in Utah, in the Rio Grande and the Colorado, and in the lakes of Colorado. Perhaps the most important of these is the steel-head trout occurring along the Pacific coast. The rainbow trout is also a fish that is highly prized along the Pacific coast. The

brook trout of western Oregon is also an important fish.

The Trout of the Great Lakes.--The fish known as trout in the Great Lakes belong to a different genus from those already mentioned, namely, genus _Cristivomer_. It has, however, the typical spots, which are of a grayish color instead of red or black like those of the other trout which have been mentioned.

The principal species which abounds in the Great Lakes is the Mackinaw trout (_Cristivomer namaycush_). It is also found in the large lakes from Maine westward to the Pacific ocean and even to northern Alaska. This is the largest species of trout. The average weight of the fish probably does not exceed 15 or 20 pounds. Individual examples have been found weighing over 100 pounds. There is only one common fish which exceeds it in weight, namely, the sturgeon. Next to the white fish it is the most important commercial fish of the Great Lakes. The supply of lake trout has been diminishing and the price increasing for several years. The spawning season of lake trout begins in September and continues until December.

Composition of Lake Trout.--

FRESH. DRY. Water, 69.14 percent Protein, 18.22 „ 60.10 percent Fat, 11.38 „ 36.80 „ Ash, 1.26 „ 4.90 „

Composition of Brook Trout.--

FRESH. DRY. Water, 77.72 percent Protein, 18.97 „ 86.62 percent Fat, 2.10 „ 9.16 „ Ash, 1.21 „ 5.39 „

The above data show that lake trout has a flesh which approximates in composition that of Pacific salmon, being quite rich in fat, while the brook trout has a composition more like the Atlantic salmon, being very rich in protein and poor in fat. Trout of all kinds are used practically in only a fresh state. The catch is not large enough to warrant the establishment of canning factories and all that are caught in the northern and central northern lakes and streams find a ready market in a fresh state at much more remunerative prices than could be obtained by canning. It is always a fortunate circumstance when the condition of the catch and of the market are such as to enable the fish to be eaten as fresh as possible from the water. Fish is a kind of food which is never improved by keeping in any way and is at its best the minute the fish is taken from the stream. The brook trout do not belong to the same genus as the lake trout but to the genus _Salvelinus_. They have a general resemblance, however, to that genus. As a fish to be caught by the hook and as a victim of sport the brook trout perhaps occupies the highest place among the fish of the country; especially is it sought for in the mountain streams, and it occurs in most parts of the northeastern United States. It extends from Maine to northern Georgia and Alabama, especially in the Appalachian Mountains and west through the Great Lakes to the Mississippi, while in Canada it is found from Labrador to the Saskatchewan.

The brook trout has been especially cultivated by the U. S. Bureau of Fisheries and introduced into waters in the United States where it is not found naturally. The season for spawning for the brook trout is in the autumn, when the water is growing colder, and continues from August to December, according to the latitude. In spawning time the fish come up into the smallest parts of the stream where shallow water can be found. The eggs remain until the next spring, when they are hatched. The brook trout varies greatly in size, according to the magnitude of the stream. In the small streams it weighs often less than ½■ pound, while in large streams it weighs 2 or 3 pounds. The large trout has almost disappeared from the small streams as a result of the activity of fishermen.

There are many other species of trout which are known in different parts of the country. For instance, the Dublin Pond trout of Dublin Pond, N. H., the Dolly Varden trout in the northern Pacific states and Alaska, the Sunapee trout in the northeastern states, and the Blueback trout in Maine. These fishes all have practically the same quality, varying only in minute details, and have the same value as a food.

=Turbot.=--A species of halibut known as Greenland halibut (_Reinhardtius hippoglossoides_) is also known as turbot in this country. It occurs chiefly off the coast of Greenland, and is taken in the very coldest part of the year. The European turbot is _Psetta maxima_.

=Weakfish.=--The weakfish belongs to the croaker family (Sciænidæ) and has a high value as a food fish, the flesh being rich in flavor and very tender and easily disintegrated, from which quality it is believed the name “weakfish” is derived. The common weakfish is the species _Cynoscion regalis_. It is also known in some localities as the squeteague. The fish is rather long in proportion to its breadth and sometimes grows to a large size. Examples weighing over 25 pounds have been captured. Very

rarely, however, does a weakfish weigh more than 10 pounds, and the average is perhaps not more than one-half that. The weakfish is, particularly when young, a victim of the bluefish, and great numbers succumb to the ravages of its more powerful enemy. The weakfish is found over the entire length of the Atlantic and Gulf coasts as far north as the Bay of Fundy. The weakfish sometimes ascends the tidal waters and congregates around the river mouths, where the food is more abundant. While found on the markets in the North, it is more highly prized in the southern markets.

Composition.--

FRESH. DRY. Water, 78.97 percent Protein, 17.45 „ 84.63 percent Fat, 2.39 „ 11.37 „ Ash, 1.19 „ 5.64 „

The flesh of the weakfish, as shown by the above data, is one in which the protein exists in very much greater proportion than the fat. It is not so rich in protein, however, as some of the other species which have been mentioned.

=Whitefish.=--This fish occurs in large numbers in all our Great Lakes, and is an abundant article of food. Its scientific name is _Coregonus clupeiformis_. It inhabits the whole of the Great Lakes regions from Lake Champlain to Lake Superior. It does not occur in very great abundance, if at all, west of Lake Superior, although it has been reported to have been found in the fresh water lakes both to the north and west of that region.

The common whitefish prefers the deep water of the lakes, coming only into shallow water near the shore at spawning time, which, in the Great Lakes, is from October to December. During the months of January, February, and March the fishing for whitefish is practically discontinued, since the fish at that time have returned to deep water and are not accessible.

The size of the whitefish in the Great Lakes is not so great as the extent of water would indicate. Probably three pounds would be an average size, although the individual fish range from 1½■ to 6 pounds. The weight rarely, however, exceeds 4 or 5 pounds. Occasionally whitefish have been found weighing as high as 20 pounds, but this is very rare. The whitefish reaches its full average size about the end of the fourth year. The number of eggs which are found in the female fish is not so large as in the shad, but usually the number does not fall below 10,000 and sometimes reaches as high as 75,000. The eggs are very small comparatively, and about 36,000 of them make a quart. The U. S. Bureau of Fisheries has done a great deal to increase the supply of whitefish by planting millions of whitefish fry in suitable water.

Different Species of Whitefish.--There are many species of whitefish besides the common whitefish which appear in the Great Lakes. Coulter's whitefish is found in the waters of British Columbia, but it is not distributed very widely throughout the country. The Rocky Mountain whitefish is very widely distributed, occurring in all suitable waters from the west slope of the Rockies to the Pacific. There is also a subspecies of this fish occurring in the headwaters of the Missouri river. Menominee whitefish occur in the lakes of New England, New York, and the Great Lakes,--it is also known as round whitefish, frostfish, shadwaiter, pilotfish, chivey, and blackback.

Composition of Whitefish.--

FRESH. DRY. Water, 69.83 percent Protein, 22.06 „ 76.00 percent Fat, 6.49 „ 21.51 „ Ash, 1.62 „ 5.36 „

Average Composition of Fish.[16]--

Water, 76.06 percent Solids, 23.94 „ Nitrogen, 3.51 „ Phosphoric acid, .52 „ Sulfur, .24 „ Fat, 1.45 „ Ash, 1.21 „ Protein, 21.92 „

[16] Average analysis of cod, halibut, bass, etc., used at the hygienic table of the Bureau of Chemistry.

=Fluorids in Fish.=--Nearly all kinds of fish yield a distinct test for fluorin which is not to be mistaken for an adulteration. The fluorin is found normally in the bones of the fish and sometimes in traces in the flesh. The addition of fluorid as a preservative is highly reprehensible, and its presence is indicated by the increase in quantity.

=Marketing of Fish.=--In the food act it is provided that no animals shall be used for food which have died otherwise than by slaughter. Whether or not this would apply to fish is a matter of some doubt. Unfortunately fish, as a rule, are allowed to die by being deprived of oxygen, which they get from the water as it passes over their gills. The common practice is to take the fish for commercial purposes in seines or other gear and allow them to die, as it were, by suffocation. The greater number of fish exposed upon our markets have died in this way and are then packed in ice and kept until sold. The ideal way to treat fish would be to

transfer them from the seine to a pool of water, fresh or salt, in which they are kept alive until they are wanted for cooking. This method is practiced in some very high-grade restaurants and hotels where the diner may pick for himself from the pool the fish he desires to eat. It is evident that for commercial purposes where a cheap food is desirable a method of this kind could not be practiced. It is a question which the hygienist as well as the practical man should consider, that is, whether or not it is possible to slaughter the fish and, as soon as they are taken, dress them, pack their carcasses in ice, and in this way deliver them to the markets. Where fish are used for canning or salting purposes they are often slaughtered as soon as caught. This is particularly true of herring captured in the Potomac and Susquehanna rivers. It is an interesting problem to study whether or not the flavor and character of the flesh are impaired by the suffocation process subsequent to their capture. In all cases except in cold weather, the fish after capture, no matter whether they are allowed to die by suffocation or slaughtered, should be packed in ice and kept until the market is reached, which should be at as early a date as possible. Fish are never so good as when fresh and the fresher the better.

=Cold Storage.=--Fish is a product which is often found in cold storage in large numbers and kept there for a long time. The usual problem attending the cold storage of food is even more important when applied to fish. In cold storage fish are frozen solid and kept in this state until ready for consumption. Just how long the palatability and wholesomeness of fish can be preserved when frozen solid has not been determined. It follows logically that the colder the temperature the less the degree of deterioration, but it does not follow logically that this temperature can be maintained indefinitely without injuring the character of the product. One thing appears to be certain, namely, that the consumer is entitled to know whether in any given case the fish he purchases is a fresh or a cold storage article. At the present time, in so far as I know, there are no national, state, or municipal laws whereby this fact can be ascertained. Without raising the question of comparative value or palatability there is no doubt but what the consumer is entitled to know the character of the fish he purchases.

=Canning Fish.=--Allusion has already been made to the practice of canning fish, especially salmon. Great precautions must be used in cases of this kind, since fish is a food which tends to develop poisonous principles incident to decomposition. Canned fish, therefore, must be thoroughly sterilized so that no fermentative action tending to produce ptomain poison can possibly take place. It should be the duty of inspectors of food to frequently examine packages of canned fish to determine, first, by the external appearance of the can, and, second, by opening a certain number of them, whether any decomposition has taken place. Too great care cannot be exercised in this matter, since dangerous and often fatal results follow the consumption of spoiled fish.

=Drying and Salting Fish.=--The preservation of fish by pickling, salting, drying, and smoking is a great industry and produces some of the most palatable products. Mackerel, herring, and cod are types of fish which upon proper curing make a most delectable dish. Nothing but encouragement should be given to industries of this kind, but in order that they be of their true value they should be conducted properly with due regard to hygienic principles and for the sole purpose of making a wholesome and palatable product.

=Adulteration of Fish Products.=--Attention has already been called to the adulteration of salmon by canning an inferior grade or even a different kind of fish under the name of a better species. The same remark may be made respecting all fish, hake, haddock, and cusk being often offered as cod. In the case of sardines a similar practice is in vogue, and the small herring which are captured off the coast of Maine are often sold under the name of sardines. The substitution of one variety of fish for another, however, is injurious only in the way of fraud, the substitute fish presumably being of equal wholesomeness to the other under whose name it is sold. On the contrary, the form of sophistication which permits the introduction of deleterious substances into fish food is highly objectionable from the dietetic point of view. Following the general principles of nutrition, all chemical, non-condimental preservatives are to be rigidly excluded from fish products. This rule excludes boric acid, borax, benzoic acid and benzoates, sulfites, formaldehyde, and all other forms of chemical preservatives.

When fish are packed in oil the character of the oil used should be made known to the consumer. Especially is this true if from the locality where the fish is preserved and the general method of packing the consumer is led to believe that a high-grade oil such as olive oil has been used.

=Value of Fish as Food.=--From the statements which have been made in connection with fish in particular and the analyses which have been given it is seen that fish is a food of a peculiarly nitrogenous character. The edible portions, exclusive of water, are at least three-fourths, and probably more composed of protein. The other edible nutritive product is fat or fish oil. The mineral nutrients compose the remaining edible portion of fish after the protein and fat are considered. The mineral portions of fish cannot be regarded as not nutritious since they contain phosphoric acid and lime, which are essential ingredients of food. The flesh of fish,

however, as it has been seen, is not a complete ration, but is lacking in carbohydrates, and for this reason fish should be eaten with potatoes, rice, or other highly starchy foods. The value of fish as a food is unquestionable and its more general consumption would doubtless prove beneficial.

Those who live in the interior of large and extensive regions where fresh water fish are not very abundant do not appreciate the value of fish as food as do those who live upon the coasts washed by salt water and near the interior fresh waters where an abundant supply of fish is secured.

SHELLFISH.

=Clams.=--Clams are shellfish which, though not so extensively used as the oyster, are valued food products. The clams of commerce are of two kinds. The species known as long or soft clam is abundant on the New England coast, and is of considerable commercial importance both fresh and as a canned product. This is the clam used at clam bakes, for which the New England coast is famous. Its technical name is _Mya arenaria_.

The other species, the round or hard clam, northward known as quahog, is the most common clam of the markets south of New York. Its scientific name is _Venus mercenaria_.

A very small round clam is known as the little neck. This has a flavor which is extremely delicate and it takes the place, in the warm months, of the blue point oyster on the menus of the hotels and restaurants. The clam may be considered as a supplemental shellfish to the oyster, being most delicious and most abundant during the closed oyster season. The average weight of the round clam is about 60 grams, of which about one-fourth is flesh, one-fourth liquid, and one-half shell and refuse. There are many specimens very much larger than this but the weight is given for those usually eaten.

Composition of Clams.--Edible portion:

Water, 78.57 percent Protein, 14.86 „ Fat, 1.78 „ Ash, 2.49 „ Undetermined, 2.30 „

The liquid which escapes upon the opening of the shell is composed chiefly of water and salt and its composition is as follows:

Water, 96.02 percent Protein, .65 „ Fat, None Common salt, 2.81 „ Undetermined, .52 „

The flesh of clams, it is seen, is not very different from that of fish in general. It is composed chiefly of water and of the nutrients the protein is the predominating constituent. The ash content is somewhat higher than is the case with fish.

If the flesh and fluid substance of the clam be considered together the composition of the whole mass is represented by the following data:

Water, 86.11 percent Protein, 8.71 „ Fat, 1.01 „ Ash, 2.63 „ Undetermined, 1.54 „

Composition of Water-free Substance of the Flesh.--

Protein, 69.37 percent Fat, 8.32 „ Ash, 11.64 „ Undetermined, 10.67 „

Composition of the Dry Substance of the Liquid Portion.--

Protein, 16.37 percent Fat, .10 „ Ash, 70.41 „ Undetermined, 13.12 „

Composition of the Dry Substance of the Flesh and Liquid Together.--

Protein, 62.81 percent Fat, 7.30 „ Ash, 18.92 „ Undetermined, 10.97 „

=The Lobster= (_Homarus americanus_).--The lobster is a crustacean which occurs along the northern Atlantic coast. Formerly it was so very abundant that it was almost a drug on the market. In the last quarter of a century the increase in the consumption of the lobster has been more rapid than the increased growth, so that the price has become higher and higher; and this, to a certain extent, is limiting the consumption. The coast of Maine is especially the fishing grounds for the American lobster, though it is found much further south and also in great abundance further north. The lobster varies greatly in size. The law, at the present time, prevents very young lobsters from being sent into commerce. They are usually from 10.5 to 15 inches in length, though

occasionally examples of enormous size are taken. The edible portion of the lobster is the liquid and the flesh of the body, claws, and tail. Only about one-half the weight of the lobster, including the liquid, therefore, is edible. The rest is refuse. In a lobster weighing a thousand grams (2.2 pounds), five hundred grams (1.1 pound) will be the average edible portion, and the other half the refuse and loss. The average lobster of the present day, perhaps, weighs scarcely two pounds, though in former times the weight was very much greater because the younger and smaller lobsters were not sent to the market. The color of the lobster as it comes from the water is dark green, almost black at times. Heat changes the color of the shell, so that after boiling or baking the lobster becomes red. The flesh of the lobster is decidedly sweet, owing to the large quantity of glycogen which it contains. There is only one kind of meat that is eaten which approaches the lobster in its content of glycogen, and that is horse meat.

Composition of the Lobster.--Edible portion:

FRESH. DRY. Water, 84.30 percent Protein, 11.63 „ 74.06 percent Fat, 1.82 „ 11.62 „ Ash, 1.63 „ 10.38 „ Glycogen, .62 „ 3.94 „

=Crabs.=--The crab is a shellfish very highly prized along the whole of the Atlantic coast. Numerous species of crabs are used for food. These are used in two forms--as hard-shelled or soft-shelled crabs. The species most valued is _Callinectes hastatus_. It is very abundant on the middle and south Atlantic coast. Crabs are quite abundant on the Pacific coast also. About 44 percent of the total weight of the crab is edible and 56 percent shell and refuse. In the edible portion about 77 percent is water and 23 percent solid matter.

Composition of the Water-free Substance of the Crab.--

Protein, 72.56 percent Fat, 8.55 „ Ash, 13.64 „

The flesh of the crab is, therefore, essentially a nitrogenous food, containing only a small quantity of fat. A considerable portion of the ash is common salt.

=Crawfish.=--The crawfish may be regarded as a fresh-water lobster. It is found practically over the whole of the United States in the fresh waters but is not used to any extent for food purposes, except on the Pacific coast. It contains even a less proportion of edible matter than the lobster. The refuse, shell, etc., form about five-sixths of its weight. In the edible portion the water constitutes 81.22 percent, while the solid matters are only 18.78 percent.

Composition of the Water-free Substance of the Crayfish.--

Protein, 85.19 percent Fat, 2.45 „ Ash, 6.98 „

=Canned Lobster, Clams, and Crabs.=--As in the case of oysters, there is a large industry in the United States engaged in the canning of the flesh of lobsters, clams, and crabs. The same precautions should be observed in the eating of these canned products as those mentioned in the case of salmon. Numerous instances of illness and sometimes of death have been recorded as the result of eating these canned products which have been imperfectly sterilized. When the flesh is canned immediately after the capture of the animal, before any incipient decomposition has taken place and when the sterilization is perfect, the canned product can be eaten without fear. Where the health of the people is so seriously involved, the factories where these products are prepared should be carefully inspected either by the municipal, state, or federal authorities. All material used in canning which is not perfectly fresh from the water is to be rejected and the processes employed in the preparation and sterilization must be those which will effectively secure a complete immunity from subsequent fermentation and the development of ptomain products.

Composition of Canned Lobster (Dry Substance).--

Protein, 81.46 percent Fat, 4.64 „ Ash, 11.23 „

As seen from the above the composition of the dry substance in canned lobster, except content of water, is not perceptibly different from that of the fresh sample.

Composition of the Dry Substance of Canned Crabs.--

Protein, 79.10 percent Fat, 7.55 „ Ash, 9.68 „

=Shrimp= (_Crangon vulgaris_).--The shrimp is a highly valued article of food, especially when it can be had fresh or properly canned. It has been a practice to ship shrimps in bulk preserved with sulfites or boric acid. This is a most reprehensible form of adulteration.

=Canned Shrimps.=--In the total dry edible portion, including solids in the liquid contents of the can, are found:

Protein, 86.89 percent Fat, 3.44 „ Crude ash, 8.84 „

In edible portion (flesh plus liquids):

Water, 70.80 percent Water-free substance, 29.20 „ Protein, 25.38 „ Fat, 1.00 „ Crude ash, 2.58 „ Extractives, 0.24 „ Nitrogen, 4.06 „ Total edible portion, 100.00 „

The above data show that the shrimp in the canned state has less water in it than in the fresh state, and contains one-fourth of its weight of protein.

=Aquatic Reptiles.=--All forms of turtle may be used for edible purposes, both of the fresh-water and salt-water species. Both the turtle and terrapin are amphibious animals; that is, they can live either in the water or on the land. Among the turtles the marine variety known as the green turtle is most highly prized for food purposes. Its Latin name is _Chelonia mydas_. It grows sometimes to an enormous size, weighing several hundred pounds, and specimens weighing 50 and 100 pounds are not unusual. It is utilized chiefly for making soup, and green turtle soup is considered of high quality by experts. The flesh is also edible, and in the making of some varieties of green turtlesoup pieces of the flesh are included.

Composition of the Green Turtle.--The edible portion of the green turtle has the following composition:

Water, 79.78 percent Protein, 19.83 „ Fat, .53 „ Ash, 1.20 „

The edible portion of the green turtle is not very large in proportion to its weight, as it forms only from 20 to 24 percent of the whole weight of the turtle.

Among the reptiles there are several aquatic species which are used as food. The most noted of these is the diamond-back terrapin, which is found in the salt-water bays, lagoons, and marshes of our Atlantic coast from New Jersey to Texas. Its center of greatest abundance is in Chesapeake Bay. There is no fish or other water animal that has a higher value for edible purposes than the terrapin. The extreme delicacy of its flavor, the richness of its aroma, and its easy digestibility give to it a rank which perhaps no other usual food product possesses. In addition to this the increased scarcity of the terrapin, especially the more famous variety of it, namely, the diamond-back, has gradually increased the cost until at the present time the terrapin is eaten only by the rich. In the United States it exists along the whole Atlantic coast from New York southward and also along the Gulf coast. Formerly it was most abundant on the Maryland coast, but the nearness of this field to the great markets of the country has resulted in such a depletion of the stock as to make the terrapin very scarce. Many attempts have been made at artificial growing of terrapin and these have been more or less successful, but have not met with pronounced success which has been expected. The enclosure in which the terrapin are kept, viz., the “crawl,” is a feature in the artificial cultivation or breeding of these marine vertebrates. It is to be hoped that greater success in the future will attend the artificial breeding of terrapin, since the natural stock seems well on the way to extinction.

Composition of the Terrapin.--Edible portion:

FRESH. DRY. Water, 74.47 percent Protein, 21.23 „ 83.13 percent Fat, 3.47 „ 13.59 „ Ash, 1.02 „ 3.99 „

=The Mussel.=--The mussel may be described as a fresh-water oyster. It occurs in almost all parts of the United States in the fresh waters and in external appearance resembles to some extent the oyster, but the shell is usually smoother. In the mussel is often developed concretions of the carbonate of lime in a particular form known as pearls. In fact the chief value of the mussel is in the supply of pearls which they furnish, since their flesh, although often eaten, is not considered very palatable nor desirable. Pearls may be found in mussels in every locality, but in some regions they are more abundant than in others,--for instance, the mussels of Wisconsin are especially noted for the occurrence of the pearls. Pearls are also frequently found in oysters, but by no means so frequently as in the mussel.

Composition of the Mussel.--The edible portion of the mussel forms about one-half its weight.

Water, 78.64 percent Protein, 12.51 „ Fat, 1.67 „ Ash, 1.73 „ Undetermined, 5.45 „

=Oysters.=--Oysters belong to a class of animals known as mollusks. They grow in salt or brackish water and are found along almost the whole of the coast of the United States. They exist in the greatest abundance along the coast in the vicinity of Long Island Sound, Norfolk, Virginia, along the coast of the Gulf of Mexico, off the coast of Mississippi, Louisiana, and Texas, and along the Pacific coast from San Francisco to the northern limits of Washington.

Size.--The size of an oyster depends greatly upon its food and also upon its species. There are some varieties which at a given period of growth are naturally very much larger than others. The larger variety grows near Norfolk and along the Gulf coast. A smaller species is especially abundant on the Pacific coast, though a number of very large specimens of oysters have been found on that coast.

Age.--An oyster is eaten at any time after two years. Oysters, however, three or four years old are, perhaps, in all respects the best. The age is determined largely by the appearance of the shell, experts being able to practically determine the age of an oyster by an examination of the shell.

The oyster grows within a shell which is composed almost exclusively of carbonate of lime. The periphery of the shell is ovoid in shape, irregular, and the surface, especially of old oysters, is corrugated, rough, and unattractive. The interior of the shell is smooth and generally white, but sometimes has a blue or reddish tinge. The shells of edible oysters vary in size from 2 to 6 inches in length and from 2 to 4 inches in width. The oysters sold in the market are known by various names, usually derived from the location from which they come. A small variety distinguished by a blue color on the inside of the shell is known as blue points. The real blue points come only from Long Island. Another variety named Rockaway is also a Long Island variety, and should come exclusively from Rockaway or vicinity. Shrewsbury is another highly prized variety from the neighborhood of Shrewsbury, New Jersey. Buzzards Bay, James River, Norfolk, Lynnhaven, Rappahannock, Stony Creek, Saddle Rock, etc., are names commonly found in the trade. Unfortunately, the name of the location is not always an indication of the actual source from which the oysters may have come. For instance the term “blue point” is now very commonly given to small oysters not exceeding 2 or 2½■ inches in length with a correspondingly diminished breadth. On the contrary “saddle rock” is a name given to very large oysters no matter from what region they may come. It is a common practice to separate the oysters taken from one location into groups of similar size and attach to each group a special name which may or may not be indicative of location.

Cultivation of Oysters.--The natural beds of oysters are rapidly exhausted by the free fishing which is in some cases allowed, and the supply must be kept up by proper cultivation. Oyster farming has become a great industry along all parts of the coasts where the conditions are well suited to culture. The ideal conditions are inlets where the oysters are protected from the action of ocean waves and where abundant food can be derived from the low marshy grounds in the vicinity. The laws in force in the states protect the oyster farms from poachers and deeds are given for oyster beds which are beyond the low water line. The conditions of culture vary in various states. The public beds are also protected by law in many states and incipient war is sometimes carried on between the authorities of one state and the poachers from other states. Maryland, especially, has laws of a very strict character respecting the taking of oysters, and the state furnishes armed forces for the protection of public beds.

Season for Oysters.--The best season for oysters on the Atlantic coast of the United States extends from September first to May. These dates may also be applied to oysters of the Gulf and Pacific coasts. It is commonly said that all months which have an “R” in them are suitable for eating oysters. In point of fact oysters are eaten the year round, especially on the Atlantic coast, though to a very limited extent during the spring and summer months. Those who own their own oyster beds are privileged to take oysters at all seasons, and it is not unusual that a restaurant furnishes oysters during the whole year, those in the closed season being derived from private beds.

Life of an Oyster.--After an oyster is taken from its bed it may be kept alive for a long time at a temperature which does not rise too high nor sink too low. The best temperature for keeping oysters alive is about 40 to 50 degrees Fahrenheit. The oysters should be protected from the sunlight by a proper covering in a cool place and kept moist with sea water or brine which is sprinkled over them in such a way as to come in contact with each oyster in the heap. Oysters kept under these conditions often remain in an excellent state for consumption for a week or ten days or even longer. If such conditions are maintained oysters may be shipped in bulk to all parts of the country in cars kept cool, and this is the best way in which oysters should be distributed for consumption in a

fresh state.

The treating of oysters with fresh water in order to swell them and thus make them appear larger and plumper than they really are is a treatment which is reprehensible in every respect. Not only does it deceive the customer in regard to the size of the oyster but it deprives the oyster of its proper taste and flavor. “Soaked” oysters quickly lose their flavor, whereas the oysters kept as above described and sprinkled with brine retain their natural flavor and odor. The objection to the transportation of oysters in this way is that the shell usually weighs many times more than the oyster and the same rate of freight must be paid upon it as upon the oyster itself. Nevertheless, the fact remains that fresh oysters should be eaten directly after removal from the shells. As soon as the shell is removed and the oyster killed by this removal it begins to deteriorate and in a short time its flavor and aroma are impaired. It is a common practice in many cities, even where oysters are delivered fresh daily from their beds, to open large quantities of them and put them in tubs and sell them from these tubs to customers. It thus happens that customers often buy oysters that have been opened 24 hours or more and which are naturally of a very changed flavor. Strict regulations in regard to the use of fresh oysters, favoring their being opened when they are ready for consumption or requiring that they should be kept in the condition of palatability and properly kept cool until ready for consumption, should be observed.

Shipment of Opened Oysters.--Opened oysters are shipped extensively to all parts of the country. After removal from the shell the oysters are washed to remove the natural water, since this becomes ropy during shipment. They are then packed in wooden tubs of various sizes, a piece of ice added, covered, and delivered to the fast express or freight service. In this way the oysters may be kept free of dangerous deterioration for several days. In such cases care must be exercised to keep the temperature low and to secure a sanitary environment. Thus protected the oysters should arrive at their destination without any further change than the necessary loss of flavor caused by the conditions of preparation and transportation.

Proportion of Shell and Oysters.--The following illustration (Report of the U. S. Commissioner of Fish and Fisheries for 1888, page 784) shows the relative proportion of the flesh, liquid, and refuse for two or three varieties of oysters:

Name: Oysters (“East Rivers”).

Locality: Cow Bay, Long Island Sound, New York.

Received: April 8, 1881, from E. G. Blackford.

Description: Length, 2½■ to 5½■ inches; breadth, 1⅜■ to 3½■ inches.

WEIGHINGS IN PREPARATION FOR ANALYSIS.

GRMS. LBS. OZ. PERCENT. Flesh, 558.0 1 3.6 10.27 Liquid, 543.7 1 3.1 10.01 Refuse (shells, etc.), 4,284.7 9 7.2 78.86 Loss, 47.3 .. 1.7 .86 ------- -- ---- ------ Total, 51 oysters, 5,433.7 11 15.6 100.00

Name: Oysters (“Sounds”).

Locality: Princess Bay, Staten Island, New York.

Received: November 30, 1881, from Dorlon & Shaffer, New York City.

Description: Thirty oysters in shell.

WEIGHINGS IN PREPARATION FOR ANALYSIS.

GRMS. LBS. OZ. PERCENT. Flesh, 384.0 .. 13.5 8.24 Liquid, 436.0 .. 15.4 9.35 Refuse, 3,816.0 8 6.6 81.87 Loss, 25.0 .. 0.9 0.54 ------- -- ---- ------ Total, 30 oysters, 4,661.0 10 4.4 100.00

The above data show that for 100 pounds of shelled oysters only about 10 pounds of meat are found. There is also about 10 pounds of liquid or juice that escapes when the oyster is opened. There is an average of 80 pounds of shell and other refuse. When it is remembered that, as will be shown in the table given below, in 10 pounds of the meat there is over 80 percent of water it is seen that the actual nourishment contained in 100 pounds of oysters is reduced to a little over 1 pound. There is a general opinion that oysters are a very nutritious food and this is true in so far as the nitrogenous element of food, that is, the protein, is concerned, and in proportion to the quantity present. As a nourishing food the oyster cannot be considered as worthy of any very great esteem. It must be confessed that it will continue to be used as it has been in the past, that is, practically, as a condimental food substance

and not to satisfy hunger nor provide the heat and energy of the human activities.

Process of Floating.--Reference has already been made to the practice of soaking oysters in fresh water for the purpose of making them more plump and increasing their weight. This, in the language of the fisherman, is called “floating,” “drinking,” or “laying out.” By this process the body of the oyster affects a plumpness and largeness which materially increases its selling qualities, as it increases its weight and size and, therefore, the profits of the dealer. The principle of this process depends upon the fact that when a soft substance like an oyster, containing a mineral salt in its composition, is brought in contact with water, a process of diffusion takes place which is known, in chemical physics, as osmosis, whereby water passes through the cell walls and enters the cells of the oyster and the mineral substance thereof is forced out into the external water. Larger volumes of water pass into the cells than accompany the particles of mineral matter to the outside of the cells and the result is a swelling of the oysters and consequent increase in the size and weight by the addition of pure water, but at the expense of the natural salt, mostly chlorid of sodium or common salt, which the oyster contains.

The U. S. Bureau of Fisheries has been experimenting to show the change which takes place with the following results:--

Result of Treatment.--As shown by the data the first result is one which would naturally be expected, namely, that the total weight of the oyster thus inflated with water is increased relatively to the total weight of the shell since no change takes place in the weight of the shell during floating. The gain of weight in the oyster is due to the absorption of the water, although there is a loss of mineral salt. The average gain of the oyster was, in round numbers, 10 percent. The danger of infecting oysters thus treated with any germs, which may be present in the water or ice used, should also be taken into consideration.

In respect of the composition of the oyster itself when subjected to floating the chief change is in the increase of the water content. As has already been said the process of floating is fatal to the flavor and palatability of the product.

Adulteration.--The chief adulterations of oysters are the “floating” above described and the treatment of the “shucked” oysters with formaldehyde, boron compounds, and other preservatives to keep them from spoiling. These processes are thoroughly reprehensible and are rapidly disappearing. The consumer who lives near the source of supply should never eat any but freshly shelled oysters and those at a distance confine themselves to the properly prepared and shipped article. The chief delight of the epicure is the freshness, and not the quantity of nourishment of this justly prized bivalve.

ANIMAL OILS.

The same distinction is made between oils and fats for animal products as has been made for the vegetable preparations further on. An animal fat remains solid or semisolid at the ordinary temperature of the living room. An animal oil, on the other hand, is one which at ordinary temperature is a liquid. Animal oils, as a rule, are not used for edible purposes directly, but are used to some extent in cooking, and to a large extent as medicinal food. Inasmuch as these oils are used for medicinal food purposes, those which are most important in this use may be very properly described in this manual. As these oils are derived both from sea and land animals they are often conveniently divided into marine animal oils and terrestrial animal oils. There is also a marked difference as a rule between the oils of marine origin and those of terrestrial origin. The oils of marine origin, as a rule, have a very high iodin number while the animal oils of terrestrial origin have an iodin number not much greater than the fats from which they are derived. This distinction corresponds somewhat closely to those vegetable oils which belong to the drying and non-drying variety. The iodin number represents the percentage of iodin absorbed by a unit weight of substance. If one gram of an oil absorb 0.67

gram of iodin, the iodin number is 67. The marine oils correspond to the dry vegetable oils and the terrestrial oils to the non-drying vegetable oils. While this difference is one which is marked, it does not always exist in each individual case.

MARINE ANIMAL OILS.

The marine animal oils may be conveniently divided into fish oils, liver oils, and blubber oils. Of these the liver oils are the most important from an edible point of view or a medicinal edible point of view. The fish oil and blubber oil are used chiefly for illuminating and other technical purposes.

=Fish Oils.=--These are obtained by rendering from all parts of a fish where fat exists. The herring, sardine, salmon, and the menhaden are the fish which are chiefly used for getting oil of this kind. The fish oils have very much improved in quality since the steamer has taken the place of the sail boat for gathering the fish. During the days of the sail boat the fish were often kept for ten days after seining before they were brought ashore. The decomposition which took place would naturally affect the oil. At the present day the steamers fishing close to the shores deliver their products much more frequently, often the same day they are caught, and thus a better quality of oil is produced. In this country menhaden is the chief fish used for obtaining oil. The scientific name of menhaden is _Brevoortia tyrannus_. These fish appear in enormous quantities around the Atlantic coast from May until November. It is estimated that nearly one-half million tons have been taken of these fish during a season. Menhaden oil is rarely if ever used for edible purposes. It is used principally in the leather trade and sometimes in the adulteration of cod liver oil made in Newfoundland.

Sardine Oil.--Sardine oil is principally prepared in Japan from the Japan sardine (_Clupea sardinus_). It is not used to any extent for edible purposes. It is also prepared to some extent in the boiling of sardines in France preparatory to packing in oil.

Salmon Oil.--This oil is obtained in large quantities on the Pacific coast. It is one of the fish oils which has an agreeable odor and taste and, therefore, can be used for edible purposes. It has a specific gravity at 15 degrees of about .926 and its iodin number is about 160.

Cod Liver Oil.--The most important of all the animal oils for food purposes is the oil which is obtained from the liver of the cod (_Gadus callarias_). Cod liver oil is valuable for food purposes not on account of its odor and taste, which are usually quite disagreeable, but by reason of the specific effect which it is often said to exercise in cases of emaciation and general disorder of the functional activities of the body. It is a food or medicine, whichever it may be best called, which is highly prized in tuberculosis and similar diseases. The oil is chiefly prepared in the Loffoden Islands. Different classes of oil are prepared which are differentiated chiefly by their color, the lighter the color the higher the quality of the oil. The chemical composition of cod liver oil is extremely complex, many different kinds of substances having been found in it by various authorities. The probability is that many of these supposed substances are only mixtures of others. Yet it cannot be denied that the number of chemical compounds occurring in cod liver oil is very much greater than that which occurs in ordinary oils. Both the medicinal and food values of the oil are often attributed to these bodies which occur in minute quantities.

Properties.--Cod liver oil at 15 degrees has a specific gravity of .922. Its iodin number varies very greatly but is always high, ranging from 150 to 180. Its refractive index is also very high, namely 1.47.

An important constituent of cod liver oil is cholesterol. Cod liver oil contains naturally a small quantity of iodin and this natural compound of iodin is one of the properties to which much of its medicinal virtue has been attributed. The quantity present is extremely minute, and probably never exceeds .002 of one percent.

Adulteration of Cod Liver Oil.--Owing to its increasing price cod liver oil has been subjected to many forms of adulteration. The chief adulteration consists in the admixture of fish liver oil of lower quality or the use of blubber oil. Seal and whale oils have been used very extensively in the adulteration of cod liver oil. Japan fish oil and, in fact, all other fish oils which are of a character not to disguise the properties of cod liver oil have been used. It is evident that it is with extreme difficulty that the presence of these adulterants can be detected, especially if they are used in small quantities. The only certain method of guarantee of the purity of a cod liver oil is in the proper inspection and control of the manufacturing works. The livers of many other kinds of fish are employed in the manufacture of cod liver oil, but the other varieties have little value as compared with the cod liver oil itself and they are probably used almost exclusively in the adulteration of the genuine article. The Norwegian cod fish gives a much better character of oil than those coming from the Atlantic coast of America. In fact the latter product is of little medicinal food value and is used chiefly

in the leather trade.

=Blubber Oil.=--Blubber oil includes the oils made from seals, whales, turtles, etc., and is used exclusively for technical purposes, unless surreptitiously placed in cod liver oil as an adulterant.

PART IV.

MILK AND MILK PRODUCTS AND OLEOMARGARINE.

MILK.

=Limitation of Name.=--By the term “milk,” unless qualified in some way, is meant a lacteal secretion of the healthy cow, free of colostrum and of standard quality. If the milk of other mammals is meant the name of the class of animal is used in connection with the term, such as ewe’s milk, goat’s milk, etc. Milk is one of the most important articles of commerce and, by reason of its composition, high nutritive character, and easy digestibility, it is not only the natural food of infants but a most important food for children and adults. It is also an indispensable food in many, if not most, cases of disease where nutrition is impaired. In some cases life may often be sustained over a critical period by the use of milk as a food where other forms of food would fail of digestion and prove injurious instead of beneficial.

The United States standard for milk is found in Appendix A.

=Average Composition of Milk.=--Perhaps there is no food substance which has been subjected to so many and such severe analytical tests as milk. Hundreds of thousands of analyses have been made in all civilized countries, not only of the milk of the individual cow but of herds of greater or less size.

There is a great variation in the composition of milk in different breeds of cattle and also in different individuals of the same breed. For instance, the Holstein breed of cattle affords a milk with a very low content of fat, sometimes as low as 3.25 percent, and in individual cases lower. On the other hand the Jersey breed of cattle affords a milk of a very high content of fat, sometimes reaching as high as 6 percent, and in individual cases very much higher. The content of the nitrogenous element in milk is more stable than that of fat and the common content of casein in milk ranges from 2½■ to 3½■ percent. The sugar in the milk is usually the complementary substance with the fat, diminishing in relative proportions as the fat increases and vice versa. The average content of sugar in cow’s milk is approximately 4 percent. The content of mineral substances in milk is also quite constant, being about 0.70. The ash contains the phosphoric acid which is one of the essential food components of milk. A milk of fair average quality contains 12 percent of solids and 88 percent of water. This is an expression for milk during the various seasons of the year and from all breeds and kinds of cows. The influence of season has much to do with the quantity of milk produced. It is always greater in the spring and summer months, when the cows are turned out to pasture and the growth on which they feed is unusually succulent. The increase in volume is not attended with a proportionate increase of solids, and thus the percentage of solids in spring and summer milk is less than that in the winter milk unless the cows are particularly well fed during the winter on a generous diet, including large quantities of roots.

[Illustration: FIG. 13.--COW STABLES, MAPLETOWN FARM, SUMNER, WASHINGTON.]

The character of the milk is greatly influenced by the environment in which the cow lives. The stable in which the cow is kept should be clean, well ventilated, and protected against extreme changes in temperature, thus being cooler in the summer than the hot air on the outside and much warmer in the winter. An excellent arrangement of the stables to secure cleanliness and good ventilation is shown in Fig. 13. Cows should be supplied with an abundant quantity of pure water and should not be allowed access to stagnant pools when pasturing in the summer. Every animal giving milk should be examined from time to time by a competent veterinarian to determine, by the injection of serum or otherwise, whether or not the animal is afflicted with tuberculosis. Every animal infected with tuberculosis should be separated from the herd and destroyed. Tuberculosis is an infectious disease and may spread from a single cow to every one in the herd. It is still by some authorities claimed that there is no authentic case of transmission of bovine tuberculosis to the human system. Other authorities hold that such transmission is possible, even if it has not been proven in a particular case. Since experts disagree on this point the same rule is applicable here as in other cases of the same kind, namely, where experts disagree on a point relating to the public health the benefit of the doubt, if any, should be given to the public, and the advice of those experts followed which is the most radical respecting the protection of health from infection of

any kind. It would be difficult to prove, for example, in any case of tuberculosis in man that it had been contracted from the sputa of tuberculosed patients, yet because it is possible, in the opinion of many experts, that such infection and transmission of disease can take place, it is the part of wisdom to guard against it.

It is, I think, a statement which will be accepted by all that it is possible in this country to secure and keep a sufficient number of healthy cows to give the milk supply of the nation. Therefore, it is the duty of the state, either by municipal, state, or federal inspection, to eliminate, as far as possible, and, if necessary, at the expense of the state, every diseased animal from the dairy herd. The farmer whose herd becomes infected through no fault of his can justly claim a compensation for the destruction of his animals for the common good. There is, perhaps, no more important point connected with the keeping of sanitary conditions than the proper inspection of the dairy, not only furnishing milk for family use, but especially for sale. It is the plain duty of every municipality and state to prohibit the sale of milk to its citizens from dairies which are not periodically and frequently subjected to the most rigid expert inspection. Such inspection would not only secure the health of the animals but tend directly toward the cleanliness of the dairy. Only by the exercise of unusual care is it possible to keep milk from becoming contaminated.

=Preparation of Milk.=--Every part of the animal, especially the udders, should be kept scrupulously clean by proper currying and washing. The milk should be collected in vessels with as small an orifice as possible. As soon as drawn the milk should be strained and artificially cooled to a temperature of at least 50 degrees F., if not lower. A convenient apparatus for cooling the milk is shown in Fig. 14. In this condition, without being exposed to infection and being protected from every point by closed vessels, stoppered when necessary by sterilized cotton, the milk is conducted into sterilized bottles and again stoppered with a sterilized cork of some description. The milk is kept cold until delivered to the consumer and by the consumer should be kept cold until used. By following these precautions it is possible to deliver a pure, wholesome, unpasteurized milk in a condition which keeps practically unchanged for even a longer period than twenty-four hours.

[Illustration: FIG. 14.--APPARATUS FOR COOLING MILK.]

=Certified Milk.=--Dairies which are inspected either by operation of the law or, voluntarily, by a competent body of medical and scientific experts duly authorized to make such inspection furnish to the market what is known as certified milk. Each bottle of this milk bears the stamp of certification and this stamp may be used from the time of one inspection until a certain date specified on the stamp when the next inspection takes place. The duty of the inspectors is to see that diseased animals are at once removed from the dairy, that the sanitary conditions of the stable are perfect, that the food is abundant and wholesome, that the milking process is conducted according to the principles above outlined, and that the proper precautions are taken to prevent infection during the preparation of the milk for the market. The milk should be examined chemically and bacteriologically at each inspection, or oftener, to see that it is of a standard quality, both in respect of the number and character of the organisms which it contains and of its chemical constituents. Certified milk is, of course, more expensive than non-certified, inasmuch as the dairy is necessarily called upon to bear the expense of inspection. However, the superior quality of such milk and its certain freedom from infection more than offsets the increased price, and makes certified milk the ideal food of a milk character, not only in the family, but especially in the hospitals, orphan asylums and other public institutions. It seems quite certain that in the near future practically all the milk that is sold upon the market of the country will be of a certified quality.

=Pasteurized Milk.=--When milk is heated to a temperature of about 140 to 160 degrees the greater part of the living organisms contained therein are destroyed. At the same time the temperature is not high enough to give to the milk that peculiar taste which it acquires when boiled. Such pasteurized milk, placed in sterilized bottles, stoppered with sterilized stoppers and kept in a cool place, will keep many days and even weeks without apparent deterioration. Physicians and hygienists are quite agreed that pasteurized milk is not so wholesome, especially for children, as certified milk which has not been subjected to a heat sufficiently high to kill the organisms contained therein. The natural ferments of the milk, namely, the enzymes which produce the lactic fermentations, promote rather than interfere with the digestion of the product. The killing of the beneficial organisms of the milk is only justified when there is danger of pathological germs being present. Hence the pasteurization of milk must in this sense be regarded as a substitute for inspection and certification.

There may arise cases where pasteurizing even of certified milk may be desirable, namely, when from necessity it must be kept for a considerable period before use, as on shipboard, and other places inaccessible to a daily supply of fresh milk. Pasteurizing is also justifiable in miscellaneous milk supplies, the origin of which is unknown. It is safer, by far in this case, to pasteurize than take the chance of consuming pathological germs.

=Pasteurizing of Milk.=--A convenient method of pasteurizing milk is recommended by the Dairy Division of the Department of Agriculture, which is as follows:

=Directions for the Pasteurization of Milk=.[20]--The pasteurization of milk for children, now quite extensively practiced in order to destroy the injurious germs which it may contain, can be satisfactorily accomplished with very simple apparatus. The vessel containing the milk, which may be the bottle from which it is to be used or any other suitable vessel, is placed inside of a larger vessel of metal, which contains water. If a bottle, it is plugged with absorbent cotton, if this is at hand, or in its absence other clean cotton will answer. A small fruit jar loosely covered may be used instead of a bottle. The requirements are simply that the interior vessel shall be raised about half an inch above the bottom of the other, and that the water shall reach nearly or quite as high as the milk. The apparatus is then heated on a range or stove until the water reaches a temperature of 155 degrees Fahrenheit, when it is removed from the heat and kept tightly covered for half an hour. The milk is rapidly cooled without removing it from its containers and kept in a cool place. It may be used any time within twenty-four hours. A temperature of 150 degrees maintained for half an hour is sufficient to destroy any germs likely to be present in the milk, in cold weather, or when it is known that the milk reaches the consumer soon after milking, and it is generally safe to adopt this limit. It is found in practice that raising the temperature to 155 degrees and then allowing the milk to stand in the heated water for half an hour insures the proper temperature for the required time. If the temperature is raised above 155 degrees the taste and quality of the milk will be affected.

[20] By Dr. De Schweinitz.

Inasmuch as the milk furnished to consumers in large cities in summer contains at the time of delivery an immense number of miscellaneous bacteria, this procedure may not fully meet the requirements during hot weather, not only because such milk will not remain sweet for twenty-four hours unless kept in a good refrigerator, but also because the bacteria not destroyed by the heating may at times produce digestive disturbances in the very young. Under such circumstances it is best to keep the bottles in the water until it boils or to use one of the many steamers now on the market. After the bottles have been kept at the boiling point for three to five minutes (or longer if they are large) they should be cooled as promptly as possible and kept in a refrigerator until used.

The simplest plan is to take a tin pail and invert a perforated tin pie-plate in the bottom, or have made for it a removable false bottom perforated with holes and having legs half an inch high to allow circulation of the water. The milk-bottle is set on this false bottom, and sufficient water is put into the pail to reach the level of the surface of the milk in the bottle. A hole may be punched in the cover of the pail, a cork inserted, and a chemical thermometer put through the cork, so that the bulb dips into the water. The temperature can thus be watched without removing the cover. If preferred, an ordinary dairy thermometer[21] may be used and the temperature read from time to time by removing the lid. This is very easily arranged, and is just as satisfactory as the patented apparatus sold for the same purpose. Any other simple method of procedure will give the same result.

[21] Before using the dairy thermometer it is best to have it tested, as it may be unreliable in the upper parts of the scale.

Average Content of Fat in American Milk.--From the thousands of analyses of American milks that have been made it appears that the average content of fat therein is about 3.90 percent. Of the different breeds of cows the Holsteins produce milk with the least content of fat and the Jerseys with the greatest. It is not unusual to find in the milk of a Jersey cow a content of 6 or 7 percent of fat.

=Comparison of Cow's Milk with Other Varieties.=--Human milk differs from milk chiefly in having a much lower content of casein and a higher content of milk sugar. Goat's milk has a higher content of casein than milk, somewhat higher content of fat, and slightly less sugar. Ewe's milk is very rich both in protein and fat. Mare's has a low casein and fat content and is exceptionally rich in sugar. Ass's milk has less casein and protein than milk but more sugar.

=Cream.=--When milk is allowed to stand for some hours in a cool place or when it is mechanically treated in a separator the fat particles, being of a less specific gravity, are separated, and when they reach a certain degree of consistence they form a product known as cream. The quantity of fat in cream varies according to the method of separation. On standing for a period of about twelve hours in a cool place the separated cream may be removed by skimming and should contain at least 18 percent of milk fat. Under the action of the separator, cream of a much greater content of fat is usually produced, often reaching as much as 30 percent or more. The separation of cream mechanically in a separator is preferable to the method of time separation by gravity alone. The cream secured by the separator is very much fresher, as it can be removed as soon as the milk is drawn and cooled. Its content of butter fat can also be regulated to the desired amount and, in the third place, a more complete separation is secured

than by gravity. By the proper manipulation of the separator almost all of the fat in milk is readily removed. Cream should be kept under the same conditions as has been described for sanitary milk. When placed in sterilized containers, properly stoppered and kept cool, fresh cream will keep sweet as long as milk under similar circumstances.

In large dairy industries the separator is practically the only method now employed for securing cream while for farm use the gravity method of standing in a cool place for twelve or twenty-four hours is the commonly practiced method.

Cream is used on the table with fruit and cereal foods and especially in beverages such as tea and coffee. It is also prescribed by physicians for certain diseases and derangement of the digestive organs where the nitrogen content of milk produces irritation and fails of digestion. Cream is not a complete food in the sense that milk is inasmuch as the other constituents of milk are less in proportion as the percentage of fat is increased, yet cream contains at least a part of all the food elements in milk, as, for example, nitrogenous constituent, principally, casein, milk, sugar, and mineral matters.

It must be remembered in this case that the fat is the variable element and as that is increased the proportion of other ingredients, necessarily, is diminished.

The most important use of cream is in the manufacture of butter.

=Standards of Cream.=--The composition of cream varies with almost every sample. The standards for cream vary in different states and cities. The national standard requires 18 percent of fat.

=Skimmed Milk.=--The residue which is left from the removal of cream is known as skimmed milk. Skimmed milk contains the principle part of the nitrogenous constituents of milk, the greater quantity of its sugar and a very large quantity of its mineral matter. It is still a very valuable food product, lacking only the element of fat. When eaten with nuts or other oily food skimmed milk would complete the ration and make a well balanced food. The chief prejudice against skimmed milk is that it has been so often sold for whole milk. When sold and consumed under its own name it is not a fraudulent body and is deserving of a higher place in the dietary than has been ascribed to it. In the large creameries of the country the skimmed milk is usually fed to animals. It is one of the most highly esteemed foods for pigs and poultry, and is largely used for those purposes.

Composition of Skimmed Milk.--Naturally the composition of skimmed milk would be that of milk corrected for the abstraction of fat. It contains some little fat when prepared by the gravity method and only a very small portion when separated mechanically. The abstraction of the fat increases the relative proportions of sugar and casein.

=Curd Test for Purity of Milk.=--The Wisconsin curd test is conducted as follows: 1. Sterilize milk containers so as to destroy all bacteria in vessels. This step is very important, and can be done by heating cans in boiling water or steam for not less than one-half hour.

2. Place about one pint of milk in covered jar and heat to about 98 degrees F. (Figs. 15 and 16).

3. Add ten drops of standard rennet extract and mix thoroughly with the milk to quickly coagulate.

4. After coagulation, cut curd fine with case knife to facilitate separation of whey; leave curd in whey one-half hour to an hour; then drain off whey at frequent intervals until curd is well matted.

5. Incubate curd mass at 98 to 102 degrees F. by immersing jar in warm water. Keep jars covered to retain odors.

6. After 6 to 9 hours incubation, open jar and observe odor; examine curds by cutting the same with sharp knife and observe texture as to presence of pin holes or gas holes. Observe odor.

7. Very bad milks will betray presence of gas-producing bacteria by the spongy texture of the curd and will have an off flavor.

8. If more than one sample is tested at the same time, dip knife and thermometer in hot water before each time used.

“Normal milk contains practically no organisms but the straight lactic acid bacteria. These germs produce no gas and no bad odors, but purely lactic acid and the curd formed therefrom is such as is represented in Fig. 17.

[Illustration: FIG. 15.--IMPROVISED WISCONSIN CURD TEST.

C, Can used to hold sample; P, pipette for measuring rennet; K, knife for breaking curd.]

[Illustration: FIG. 16.--A, MILK; B, BROKEN CURD IN WHEY; C, MATTED CURD.]

[Illustration: FIG. 17.--CURD FROM A GOOD MILK. LARGE, IRREGULAR HOLES MECHANICAL.]

[Illustration: FIG. 18.--CURD FROM A TAINTED MILK. LARGE, IRREGULAR HOLES MECHANICAL; SMALL PINHOLES DUE TO GAS.]

[Illustration: FIG. 19.--CURD FROM FOUL MILK.]

“Milk contaminated by the introduction of dust, dirt, fecal matter, or kept in imperfectly cleaned cans becomes fouled with gas-producing bacteria that break down the milk sugar and so produce gases and usually undesirable odors.... Therefore milks showing the presence of gas or bad odors in any considerable degree are milks that have been more or less polluted with extraneous organisms or carelessly handled, and as a consequence such milks show a type of curd revealed in Figs. 17, 18, and 19.

=Whey.=--The residue left from milk in the process of the making of cheese is known as whey. Whey consists of that portion of milk which is not precipitated by the rennet and which separates when the casein of milk is coagulated and sets in the process of cheese making. The whey contains the principal portion of the water in milk, the most of the milk sugar therein, and small quantities of butter and soluble nitrogenous portions (albumin) and solid particles which remain suspended in the solution. It may, therefore, be properly considered as milk from which the greater part of the nitrogenous portions and fat particles has been separated. The value of whey as a food product consists chiefly in the milk sugar which it contains. It is not very largely used for human food but is valued as a food for young domesticated animals, especially pigs and poultry.

=Composition of Whey.=--The whey resulting from the manufacture of cheese contains nearly all the foods of the whole milk with the exception of the casein and fat. It is composed of from 6 to 8 percent of solids consisting chiefly of milk sugar, some albumin, a little fat, and about 0.6 percent of mineral matter.

=Koumiss.=--Koumiss originated in Asia Minor in the production of a fermented drink from mare’s milk, which is richer in milk sugar than the lactic secretions of most other mammals. By the fermentation of the milk sugar mare’s milk is converted into a fermented beverage containing a small percentage of alcohol. In this country koumiss is made almost exclusively from cow’s milk and by special fermentation at a low temperature. It is a beverage valued especially by convalescents and invalids and frequently is capable of nourishing the body in diseases which affect the digestive organs when other foods fail of assimilation. It is also a cooling and delicious beverage for those in health when properly prepared and stored.

Modified Koumiss or Kephir.--Koumiss made from cow’s milk with the previous addition of milk or cane sugar to increase the alcoholic content cannot be regarded as a natural product but rather one to which the term “modified” may be applied. The greater part of koumiss made in the United States from cow’s milk is of this modified variety. Cow’s milk contains on an average about 4 or 5 percent of sugar and does not yield a fermented beverage of a sufficient alcoholic content without reducing the actual sugar content of the beverage below the point of palatability. Cane sugar is usually employed as the modifying agent. While modified koumiss cannot be regarded as of equal value with the natural article made from mare’s milk it is a palatable and wholesome beverage when produced and stored under proper conditions. The quantity of alcohol produced in any case is not very great and the change in composition which renders koumiss so easily assimilable in many cases cannot be due alone to the alcohol formed but to the fermentative changes produced by enzymic action which takes place in the other constituents of koumiss, especially casein during the process of fermentation.

Koumiss or kephir, which is the name applied to koumiss made from cow’s milk, is also prepared with the addition of honey, in the place of sugar, and small quantities of wheat flour, not exceeding 20 parts to 1500 parts of other constituents. Koumiss is sometimes artificially fortified by the addition of small quantities of alcohol, but this practice must be regarded as extremely reprehensible. The alcohol of koumiss is incident to its fermentation and should not be increased beyond the normal amount. One of the important points in the making of koumiss is the control of the temperature which, during fermentation, ought not to rise above 50 degrees in order to get the best results. Koumiss may be made in the bottle in which it is kept, in fact, it is best made so, and its fermentation then resembles that of champagne. During the process of fermentation the bottle should be shaken at least once a day in order that the part which coagulates cannot be unevenly distributed throughout the mass. The bottle should be strong enough to resist the pressure produced by the carbon dioxid which is formed and the cork should be securely tied in. As in the case

of champagne it is best to place the bottle with the cork down. Before using, the bottle containing the koumiss should be well shaken in order to thoroughly mix the contents which form a creamy, foamy mass extremely palatable, highly nutritious, and valuable not only as a beverage but in many cases of disease and disordered digestion as a food. In fact the value of koumiss for medicinal purposes, that is for medicinal food, is not thoroughly appreciated by the medical profession. This may be due to the fact that the art of making koumiss is not generally known, and while the general principles upon which its manufacture is based have been set forth it requires an expert to make a palatable and useful article ("British Dairy Farming" by Jas. Long). It is worthy of suggestion now that the use of horses for draft purposes has practically been superseded by the automobile and the trolley that the production of real koumiss from mare's milk might become a very useful field of industry in the United States. It is perfectly certain that the genuine article must possess properties which are not wholly found in the imitations of koumiss which are so common in this country. It is well understood by physicians that a natural product produced from natural material is always superior in character both as a food and medicine to the synthetic or artificial product. Whenever, therefore, a fermented beverage produced from natural sources is contaminated by artificial products the resulting compound is not so useful nor digestible. For instance, wine which is made partially from sugar and beer made partially from dextrose, although they may be healthful and wholesome beverages, are inferior in quality and character to the real product made from grape juice or barley malt.

=Buttermilk.=--The residue left in the churn in the manufacture of butter is termed buttermilk. There are two distinct varieties of buttermilk, namely, that resulting from the churning of unsoured cream and that remaining from the churning of soured and ripened cream. The first kind of buttermilk does not differ in its characteristic essentials from skimmed milk and therefore is not considered here. The second class of buttermilk is far more common and is a beverage of pleasing acid taste. When made from properly ripened cream it is wholesome and delicious, especially in summer time. Its composition is that of cream subjected to enzymic action during the ripening process by which an agreeable degree of acidity is produced due to lactic acid, together with the incidental changes which take place in the composition of other parts of the liquid due to enzymic action. Buttermilk also usually contains small particles of butter itself which escape aggregation during the final process of churning. In well prepared buttermilk, however, these particles of butter are not very numerous and they add nothing to the palatability, although they do add something to the nutritive properties of the beverage. The buttermilk represents that portion of milk which is one of the chief constituents of cream as far as bulk is concerned, freed practically from its butter fat. It does not differ greatly, therefore, in its chemical properties from skimmed milk, although there is a slight difference in the relative percentages of the milk solids in cream as compared with the same constituents in whole milk. The composition of buttermilk is shown in the following table:

COMPOSITION OF BUTTERMILK.

FROM SWEET FROM SOUR CREAM. CREAM. _Percent._ _Percent._ Water, 89.74 90.93 Fat, 1.21 0.31 Milk sugar, 4.98 4.58 Protein, 3.28 3.37 Ash, 0.79 0.81 Acidity, ... 0.80

=Bonnyclabber.=--Bonnyclabber is a term applied to milk which has become soured by lactic fermentation, producing a gelatinous coagulation of casein which is sufficiently firm at times to prevent the liquid from being poured. Clabber may be regarded as a natural cheese curd except that the fat is chiefly on top. It is a beverage or food of a very agreeable taste to most persons and is often eaten with sugar. In the summer it is often formed during hot murky weather, especially of that character which produces thunder storms. For this reason it is a common supposition that thunder or lightning sours milk. The thunder and lightning, however, have nothing to do with this process. The condition of the atmosphere which produces an environment favorable to electrical disturbances of this kind also favors in the highest degree the growth of the organisms which produce the lactic ferments. Hence thunder storms and the rapid souring of milk are frequently coincident leading to the popular impression as above mentioned. Inasmuch as the souring of milk usually takes place after the cream has risen the composition of clabber is practically that of skimmed milk modified by the lactic fermentation which has taken place.

BUTTER.

When cream, especially cream in which incipient lactic fermentation has been set up, is subjected to agitation in a churn under proper conditions of temperature the particles of butter therein contained are collected into masses so that the butter can be separated from the residual liquid. This process is technically called churning. The domestic churn in its simplest form is perhaps well known to almost everyone, especially those who have lived in the country. In the domestic manufacture of butter the cream is collected and set aside until sour, that is, until lactic fermentation has set up. When this is sufficiently advanced the cream is placed in a churn, the simplest form of which is a wooden, cylindrical vessel of appropriate size, being much longer than its horizontal

diameter. The churn is provided with a dasher, namely a perforated wooden disk with a handle which passes through a hole in the cover. When the churn is charged the butter is produced by agitation with the dasher. In winter time warm water is added to the mixture in order to raise the temperature to the proper gathering point of butter, namely 65 to 70 degrees F. For the same reason cold water is added in the summer time. The art of the dairy maid is shown in the proper regulation of the temperature to secure the best results. When the cream is properly ripened and the temperature is suitable the gathering of butter will be accomplished in from twelve to thirty minutes. In unfavorable conditions the duration of churning may be for a much longer period.

[Illustration: FIG. 20.--POWER CHURN READY FOR USE.--(_Courtesy of the Bureau of Animal Industry._)]

In dairies and large establishments churning is accomplished by machinery with very different mechanical appliances, but the principle which underlies the process is the same as those outlined above. The accompanying figures illustrate the process of churning by mechanical means in a modern dairy (Figs. 20 and 21).

[Illustration: FIG. 21.--POWER CHURN, OPEN.--(_Courtesy of the Bureau of Animal Industry._)]

=Treatment of Butter.=--The crude butter secured by churning is subjected to washing and seasoning processes in order to prepare it for the market. The washing or working of butter is accomplished by means of water. The object of this “working” is to separate from the crude butter as much of the curd and other non-fatty constituents of the cream as can be conveniently accomplished. The removal of these mechanical particles not only makes a butter of a higher grade but also one of better keeping qualities. The working of butter also has much to do with its grain or texture, which is one of the characters of butter to which great attention must be paid. The best grade of butter and that which brings the highest price in the market is that which receives no treatment other than that of the washing and working process to which attention has been called. This kind of butter is known as natural or unsalted or uncolored butter, that is, a fresh, sweet product of an agreeable aroma, palatable, of fine texture and grain, and is the best product of its kind for human consumption. It also brings the highest price on the market and, by reason of its method of preparation, the consumer can usually be assured that it is fresh in character.

=Salting Butter.=--In the United States, especially, consumers of butter generally require that it shall be salted. For this purpose fine grades of dairy salt are used as free as possible from impurities and consisting of fine particles or crystals which rapidly dissolve in the residual moisture of butter. This promotes a uniform distribution of the salt in the form of brine throughout the mass of butter. The existence in butter of undissolved particles of salt is highly prejudicial to its taste and character. The quantity of salt used in butter is determined by the taste of the consumer. The more salt the butter contains the less value it is as butter and hence the quantity should be limited to the smallest possible amount demanded by the consumer’s taste. Often butters are found in commerce which are so full of salt as to be wholly unpalatable and there is a tendency on the part of the greedy manufacturer to add excessive quantities of salt because it is very much cheaper than the butter itself and thus he hopes to add to the profit of the industry. On the contrary this practice usually results in loss, since such highly salted butter naturally brings the lowest price. The amount of salt which is used in butter should not exceed two percent.

It is a common supposition that salt in butter is a preservative. This is true when used in large quantities, that is, in quantities which render the butter somewhat unpalatable. The very small quantity of salt used purely for condimental purposes cannot be regarded as aiding in any material way the preservation of the product.

=Coloring Butter.=--Unfortunately the practice of artificially coloring butter is very prevalent in the United States. Practically all the butter found upon the market, even in the spring and summer, is more or less artificially colored, often with coal tar (anilin) dyes which, to say the least harm of them possible, are open to suspicion in respect of wholesomeness. The practice of coloring butter produced in winter may be regarded as universal, though none the less reprehensible on that account. The object of coloring butter is, undoubtedly, to make it appear in the eyes of the consumer better than it really is, and to this extent can only be regarded as an attempt to deceive. If cows are properly fed during the winter months with wholesome, nutritious food to which a small proportion of roots such as carrots or ruta bagas are added or with yellow maize and clover hay, even in winter time the butter produced will have an attractive light amber tint which appeals strongly to the æsthetic sense of the consumer. The natural tint of butter is as much more attractive than the artificial as any natural color is superior to the artificial. There is the same difference between the natural tint of butter and the artificial as there is between the natural rose of the cheek and its painted substitute. It is claimed, and perhaps justly, that the use of certain vegetable colors, such as annotto, does not introduce any unwholesome substance into the product. Admitting this, we must next ask whether it deceives the consumer. If so, it is difficult to understand upon what ethical principal any plea for the artificial coloring of butter can rest. If it is admitted that there is no valid reason why butter should be colored other than

the artificial coloring of foods in general, which is a practice so reprehensible that it is almost universally denounced, its practice cannot be easily defended. The dairymen of our country are honest and honorable and evidently do not clearly see the false position in which the practice of coloring butter puts them. When the dairymen of our country understand that the naturally colored products will bring the highest price on the market and appeal more strongly to the confidence of the consumer it is believed the artificial coloring in butter will be relegated to the scrap pile of useless processes. It cannot be claimed in any sense that coloring of butter artificially ever adds anything to its value as a nutritive substance.

One of the claims for justifying the coloring of butter is that it distinguishes it from oleomargarine. This, however, is not the case since, under the law, oleomargarine may be colored upon the payment of a tax of ten cents per pound. The consumer has at his disposition a complete protection against fraud in the use of oleomargarine by the operation of state and federal laws, irrespective of the tint of the product. Oleomargarine and butter are distinguished from each other by their natural colors and also by their chemical and physical properties and, therefore, there can be no justification for the coloring of butter on the plea that it distinguishes it from oleomargarine. Thus, from every point of view it is evident that the artificial coloring of butter is undesirable. It interferes with the right of the consumer, who should know the exact character of the product he buys, and it stands in the way of the prosperity of the manufacturer by keeping upon the market a cheaper product which tends to decrease the price even of that of better quality.

=Standard Butter.=--According to the standard established by Congress butter must contain more than 16 percent water and not less than 82.5 butter fat.

=Renovated Butter.=--The law of Congress which controls the manufacture of renovated butter is executed jointly by the Treasury and Agricultural Departments. The quantity of renovated butter produced during the year ending June 30, 1905, was 60,290,421 pounds.

=Adulterated Butter.=--The quantity of adulterated butter which was produced under the authority of the Act regulating the manufacture of oleomargarine and butter and on which is laid a tax of 10 cents per pound during the fiscal year ending June 30, 1905, was 3,671 pounds. These data show that the tax of 10 cents per pound laid upon adulterated butter has practically destroyed the manufacture of that article. Normal butter has from 12 to 14 percent of water. It is sometimes rechurned with water to raise the water content to 16 percent. Such a practice results in adulteration whether the content of water exceeds 16 percent or not.

=Influence of Food upon Butter.=--The character of butter is very easily affected by the nature of the food consumed by the cow. Butter has the faculty of absorbing very readily odors of all kinds. Foods, therefore, which have characteristic odors impart them to the butter. A most striking instance of this is in the eating of wild garlic. In this case both the milk and the butter are affected to such a degree as to be in many cases unpalatable. Hence foods or substances in foods which are aromatic or odoriferous are likely to impart their peculiar odor to the milk, cream, and butter. Of all the constituents of milk the fat appears to have the highest faculty of absorbing these objectionable odors. Therefore, the feeding of distillery slops is also apt to impart an unpleasant odor to milk and butter, whereas if these slops be dried and their volatile aromatic principle expelled little discomfort is experienced in their use. The physical characteristics of butter are also changed in a marked degree by the character of the food. Butter fat, as has already been indicated, is distinguished from other animal fats by its content of soluble and volatile acids of which butyric is the chief. There are certain kinds of foods which decrease or tend to decrease the content of butyric acid in butter.

=Influence on Melting Point.=--The character of the food also has a marked influence upon the melting point of butter. The author showed many years ago that the use of cottonseed meal as food for cows tends to raise the melting point of butter. This was regarded as an index of some value for the southern portion of the country, where a high temperature obtains over a period of six or seven months of the year. If the melting point of butter, which when normal is about 33 degrees C. (91° F.), could be increased to 35 or 36 degrees C. (95° F.), it would be of immense advantage in these warm climates and, in fact, in all parts of the country during the months of July, August, and September. There is no apparent tendency to increase the melting point of butter by feeding other oil cakes.

=Transmission of Other Principles in the Food to the Butter.=--Experience has shown that when cows are fed cottonseed meal or its products the quality of cottonseed oil which responds to the color test known as the Halphen test, namely, the production of a red color with carbon disulfid and amyl alcohol, is transmitted also to the butter. In some cases this reaction is extremely faint while in others it is displayed with an intensity which is claimed by some to be equal to that of the admixture of 5 percent of cottonseed oil

with the butter. The use of cottonseed meal, on the contrary, does not seem to notably affect either the content of volatile acid in the butter nor its refractometer reading. (Experimental Station Record, Volume 25, Page 716.)

OLEOMARGARINE.

Oleomargarine is the name applied to any fatty substance which is prepared to be used in the same manner as butter. Oleomargarine is defined by Act of Congress as follows:

An Act defining butter, also imposing a tax upon and regulating the manufacture, sale, importation, and exportation of oleomargarine. (Approved August 2, 1886.)

“That for the purposes of this act certain manufactured substances, certain extracts, and certain mixtures and compounds, including such mixtures and compounds with butter, shall be known and designated as “oleomargarine,” namely: All substances heretofore known as oleomargarine, oleo, oleomargarine oil, butterine, lardine, suine, and neutral; all mixtures and compounds of oleomargarine, oleo, oleomargarine oil, butterine, lardine, suine, and neutral; all lard extracts and tallow extracts; and all mixtures and compounds of tallow, beef fat, suet, lard, lard oil, vegetable oil, annotto, and other coloring matter, intestinal fat, and offal fat made in imitation or semblance of butter, or, when so made, calculated or intended to be sold as butter or for butter.”

The manufacture of oleomargarine can only take place in the United States under the supervision of officials of the Internal Revenue. All oleomargarine which is artificially colored a yellow or yellowish tint in semblance of natural butter pays an internal revenue tax of 10 cents per pound. Oleomargarine uncolored pays a revenue tax of one-fourth cent per pound. Oleomargarine when made under proper sanitary conditions from sanitary raw materials is a wholesome and nutritious article of diet and usually can be sold at a smaller price than butter. It is especially a food product which commends itself to those who are under the necessity of practising strict economy in the cost of food in the family. The principal objection, and in fact the only valid objection, to its use is found in the frauds which have been committed in its manufacture and sale. There has been a constant disposition on the part of dishonest manufacturers and dealers, since the time when oleomargarine became a commercial commodity, to sell it as butter. Although the penalties of national and state laws are very severe in this respect the practice is continued. The opportunity for gain is so great that the cupidity of the manufacturer overcomes his fear of punishment and disgrace. With a more rigid national and state inspection, it is reasonable to hope that this fraudulent use of oleomargarine can be avoided and the pure, unadulterated article under its own name be supplied to those who prefer it either on account of its properties or its price.

=Materials Used in the Manufacture of Oleomargarine.=--_Neutral Lard._--One of the principal basic components of oleomargarine is neutral lard or lard stearin, the properties of which have already been described. Beef fat stearin is another basic ingredient of oleomargarine and is the stearin derived from tallow or tallow itself. Beef fat has a higher melting point than lard and beef fat stearin a still higher melting point than the tallow. Hence it forms an ideal ingredient with which to mix the oily components which enter so largely into the manufacture of oleomargarine. The beef fat or beef fat stearin is easily distinguished by means of the microscope. It forms beautiful radiated fan-like crystals, the characteristic appearance of which is shown in Fig. 9, page 67.

Cottonseed Oil and Cottonseed Oil Stearin.--These are also important ingredients of oleomargarine affording the oily or more liquid constituents which, when mixed with the lard and stearin above mentioned, form a compound the melting point of which is slightly above that of butter and sufficient to maintain it in an unmelted state even in warm weather. The quantities in which these different ingredients are used vary greatly in different manufacturing establishments and depend largely upon the location where the oleomargarine is to be used. When manufactured for tropical or subtropical regions larger quantities of stearin are employed than when used in temperate zones or for winter consumption, in which case larger quantities of cottonseed oil and cottonseed oil stearin are employed with the mixture. After the fats are mixed it is usually the practice to churn them with milk in order to give a flavor of butter to the product. In some cases the yolk of eggs is mixed with oleomargarine, as it is claimed that they impart thereto a firmer and more homogeneous structure which renders the mass better, especially for cooking purposes. All the ingredients which are used in the manufacture of oleomargarine are made known and recorded in the books of the Commissioner of Internal Revenue and thus it is a product which it may be said is strictly under government supervision.

=Description of Process of Manufacture.=--The fat is taken from the cattle in the process of slaughtering, and after thorough washing is placed in a bath of clean, cold water, and surrounded with ice, where it is allowed to remain until all animal heat has been removed. It is then cut into small pieces by machinery and cooked at a temperature of about 150 degrees until the fat, in liquid form, has separated from the fibrine or tissue, then settled until it is perfectly clear. Then it is drawn into graining vats and allowed to

stand a day, when it is ready for the presses. The pressing extracts the stearin, leaving the remaining product, which is commercially known as oleo oil, which, when churned with cream or milk or both and with or without a proportion of creamery butter, the whole being properly salted, gives the well-known food-product, oleomargarine.

=Adulteration of Oleomargarine.=--Since the coloring of oleomargarine is permitted upon the payment of a tax, oleomargarine which is colored cannot be said to be adulterated when the tax has been paid, although if coloring were not a legalized operation it would be an adulteration. Yellow oleomargarine is an imitation of natural butter and its manufacture should be prohibited unless the product is marked “imitation.” The character of the coloring materials used is not prescribed by the Commissioner of Internal Revenue but as a rule the coal tar dyes are preferred in the coloring of oleomargarine to the vegetable coloring matter such as annotto and saffron. The remarks which have been made in connection with the use of poisonous materials in other products apply to oleomargarine.

Adulteration with Egg Yolks.--An adulteration which has been practiced in this country is the admixture of preserved egg yolks. Usually these yolks are secured in China, broken, and placed in vessels and preserved with borax or boric acid or salt. These eggs are generally collected during the early spring and summer months and are not sent to the United States until the fall or winter. The importation of such articles is now prohibited under the food laws of the country so that the adulterations with the imported article is no longer to be feared. It is possible to preserve domestic eggs in the same way, and the use of them in this manner is regarded as an adulteration, since such preserved egg products cannot be regarded as suitable for human food.

Adulteration with Preservatives.--Fortunately preservatives are not used to any extent in the manufacture of oleomargarine when intended for domestic use. The most suitable preservative in such a case as this would be borax or boric acid. It is not believed that these preservatives are used to any extent when the product is intended for domestic consumption. Whether or not preservatives are used in the product sent abroad I am unable to say.

=Production of Oleomargarine.=--According to the report of the Commissioner of Internal Revenue the quantity of oleomargarine taxed at 10 cents a pound produced in the United States for the fiscal year ending June 30, 1905, was 5,584,684 pounds, and for 1906, 4,888,968 pounds. The quantity produced in 1906 taxed at one-fourth cent a pound was 50,545,914 pounds.

COMPOSITION OF OLEOMARGARINE.

SOL. SOL. SPECIFIC IN- ACID BY ACID BY GRAVITY SOLUBLE WASHING DISTIL- ALBU- AT 40°C. WATER. ACID. OUT. LATION. SALT. MINOIDS. .90490 9.34 93.59 0.12 0.25 3.64 0.35

From the above data it is seen that the objections to the use of oleomargarine are more on the grounds of fraud and deception than in regard to nutritive and dietetic value. The components used in the manufacture of oleomargarine, when properly made, are all wholesome and digestible materials such as are consumed in eating various food products. It does not appear, therefore, that any valid objection can be made against the use of oleomargarine from a physiological or hygienic standpoint.

CHEESE.

=Historical.=--The preparation of cheese is one of the oldest of the technical processes. It appears that it was known during the time of King David, at least a thousand years before Christ, and the Greeks were acquainted with it before the writings of Homer. Aristotoles and Hypocrates describe the curdling of milk which at that time appears to have been accomplished by the use of the juice of the fig. The use of cheese was very common in Rome in the earlier historical days but the most of it was imported from the North. Cæsar speaks of the preparation of cheese among the German tribes. Cheese must, therefore, be regarded as one of the very oldest forms of prepared food used by man. It probably is almost, if not quite, as old as wine. These historical facts are interesting in showing how from the earliest times man has made use of the natural ferments to prepare food from the raw material. Attention must be called in this connection to the fact that many people claim that such foods as these are not natural foods but wholly artificial. The fallacy of such a claim is not difficult to show. An artificial food is one which is prepared out of materials which, themselves, are not edible food products or, at least, are not digestible or of a character which does not naturally occur by ordinary processes. Artificial foods, therefore, are purely synthetic, that is, made up from the elemental substances, or they are mixtures or compounds. On the contrary a food like cheese or wine is not a mixture or compound but a natural product from materials which themselves are food products. Milk is the raw material of cheese as the must of the grape is of wine. Both milk and must are rich and nutritious foods. The changes which each undergoes are in many respects the same. The must of wine undergoes an alcoholic

fermentation and the milk sugar of cheese is subjected to a lactic fermentation and its casein to a proteolytic change which materially alters its character.

Cheese products are a very important part of food materials of the dairy. The term cheese is applied to the solid product produced from milk by coagulation of the casein with rennet or lactic acid and subjecting the solid product thus produced to a process of fermentation and ripening by the addition of appropriate seed material, seasoning, and storage at convenient temperature for varying periods of time. In the precipitation of the casein of milk the fat particles become mechanically entangled and form a part of the precipitate. There is a certain quantity of other milk constituents incorporated in the form of water, milk sugar, and mineral matter in the precipitated mass. The greater part of the other bodies which the milk contains, consisting of the milk sugar and a considerable portion of the soluble mineral matter, are separated in the form of whey. The composition of fresh cheese is that of that part of the milk which is precipitated and which is entangled mechanically in the precipitated matter. The ripened cheese is changed in its chemical constituents mostly as the result of fermentative action upon its nitrogenous constituents, that is, the casein, albumin, etc., contained therein. The ferments tend to change the casein into a more soluble form of protein, while at the same time they develop a flavor and aroma in a way agreeable to the nostril and palate. Various forms of moulds and other organisms grow on and in cheeses which influence their palatability and character. The final product of the ripened cheese varies not only with the nature of the original material as determined by the milk itself but with the character of the preparation and the nature of the organisms and ferments which are active during the ripening period, and also with the time and temperature of storage.

=Kinds of Cheese.=--It is not necessary and perhaps it would be impossible to attempt an enumeration of all the various kinds of cheese which are offered on the market. The first classification of cheese depends upon the character of the milk used. The term “cheese” in this country naturally refers to a product made from cow’s milk since that is the principal milk used in the United States for cheese making. The term is used in this manual in that sense and when there is no qualifying word employed it is always understood that the product in question is made from the cow’s milk. This implies that the milk is at least a standard milk, that is, a whole milk, unskimmed and containing not less than 3.25 percent of butter fat. According to the definition fixed by the Congress of the United States the term cheese is applied not only to this product but also to one containing a larger percentage of fat than this. The term cheese applies both to cheese made from milk and cheese made partially from milk and partially from cream. The term “full cream cheese” is also often used in the trade but is likely to be misleading and deceptive. The real significance of the term full cream cheese is that it is made of whole milk or milk unskimmed which contains its full complement of cream. The term “cream cheese” is also often used to indicate a cheese made partially of milk and cream. It is evident that the term cream cheese in this sense is misleading, since it can be properly applied only to a cheese made from cream alone. Such cheeses are made but, inasmuch as cream must have not less than 18 percent of fat in order to be called cream according to the United States standard, the cheeses made from such a source are too oily and fatty for ordinary consumption.

=Cheese Made from Goat’s Milk.=--Goat’s milk is also frequently used in making cheese. It is extensively employed in France and Switzerland for cheese making and also in other parts of Europe, and to a limited extent in this country. Some of the varieties of cheese which are most highly prized are made from goat’s milk, such as Roquefort.

=Adulteration and Misbranding of Cheese.=--The most common form of adulteration or sophistication of cheese is the misbranding thereof in respect of the country where made or in respect of character. This is a form of deception which has long been established in the trade and one which cannot be condoned or excused. There are certain varieties of cheese whose names should be respected and in fact, in the case of all varieties that have an established character and reputation, their name should not be applied to other articles made in imitation thereof. In this country there is a national law which prohibits the marking of a food or dairy product falsely as to the state or territory where made. For instance, a cheese made in Ohio cannot be marked New York cheese and peaches grown in Delaware cannot be marked California peaches, maple sirup made in Indiana cannot be labeled Vermont maple sirup, etc. The ethical principle underlying this law is one which will meet the approbation of every well meaning man and therefore the extending of this principle to other forms of misbranding is an easy step. If it is a violation of the law to mark a cheese made in Ohio as made in New York it is certainly a violation of the ethical principle underlying that law to name a cheese made in Connecticut Cammerbert. Unhappily, however, there are cheeses made in the United States to which foreign names are given, the universal excuse being that they are cheeses of the same type. In many cases this excuse is not a valid one and in no case is it an accepted one. To name a cheese made from cow’s milk the same as that made from ewe’s milk is a distinct misbranding in every sense of the term. There should be no difficulty in established varieties of cheese made in this country having

names which are not deceptive and not intended to mislead the consumer as to the state, territory, or country where made. In one sense all cheese may be said to be of the same type, but because the taste and odor of a cheese made in the United States imitates to some extent that of a cheese made in France is no excuse for giving the French name to the American product. A further illustration of this principle is found in the following: The term Roquefort, for instance, is not properly applied to any cheese product except that which is made at or in the vicinity of Roquefort. In no other part of France can cheese be made bearing the name of Roquefort. The use of the term Roquefort, therefore, in any way upon American cheese is a misbranding and an attempt to deceive which usually is successful. There is not so great an objection to the term Swiss cheese as to Roquefort, but there is the same kind of an objection. The cheese which bears the name of Schweitzer-Käse is very extensively manufactured in Germany and sold under that name. A similar cheese is also extensively made in this country and sold under the name of Schweitzer-Käse. In this case there is no particular location or place which originated the name and has the sole right to use the name Swiss cheese. It is the name of a whole country and not of a location, and yet it is evident that Swiss cheese properly can only be made in Switzerland and not in Germany or in the United States. Any hard, tough cheese in which a large number of holes is found and which on cutting makes a flexible, semi-leathery slice has to a certain extent the appearance and perhaps the taste and flavor of genuine Swiss cheese.

It should not be difficult to find a market for all good cheese made in this country, under appropriate American names indicating their origin. If the term Swiss cheese is at all allowable on a package it should be placed as a minor part of the label and with the statement that it is of that type. Even this transgression is perhaps difficult of excuse.

=Artificial Coloring.=--Next to misbranding and misnaming of cheeses, perhaps the most common adulteration is that of artificial coloring. The public taste has been led in the matter of cheeses, especially of American origin, to look for a deep yellow color. This is also associated with the idea of the use of a large quantity of rich, naturally yellow-colored cream. The addition of an artificial color to a cheese never adds anything to its value, and to the really æsthetic eye detracts much from its appearance. The presence of this rich artificial tint is calculated in many instances to excite a suspicion in regard to the character of the cheese and thus interferes with its proper gustation. There is another more serious objection than the one just mentioned, namely, that it is possible from skimmed milk to make a highly colored cheese which would appear to the consumer to be made of whole milk or of milk and cream, and thus a deliberate deception is perpetrated. The consumer of cheese should demand that artificial coloring of all kinds be omitted from cheese products.

Moreover, these colors may of themselves be deleterious in character and there is no restriction, so far as I know, at this time in the United States to prevent a manufacturer, if he so desires or through his ignorance of the use of coloring materials of a poisonous character, from using any amount.[22] The coal tar dyes are cheaper and produce faster and more natural looking tints than the vegetable colors such as annotto and saffron, and hence, unless they are prohibited by law, they are almost universally employed. All of these dyes in a concentrated form are highly poisonous and injurious and several instances are on record of death, especially in the case of young children, from eating concentrated colors. The fact that a poison of this kind is diluted by the cheese is no excuse for its use. The only protection which the consumer has, which is reliable in all cases, is the prohibition of coloring matter in cheese.

[22] Written before the passage of the food-bill.

By Act of Congress of June 6, 1896, coloring matter is permitted to be used in cheese in the United States and doubtless it will continue to be used under this authority until that portion of the Act is repealed or until the consumer demands an uncolored article. The pure, natural color of the cheese is universally acknowledged to be best, most palatable, and most desirable.

=Preservatives.=--Fortunately there is little to be said in regard to preservatives in cheese because they are almost unknown. The addition of a preservative to a cheese at the time of its production would so seriously interfere with the ripening process as to defeat the purpose of storage altogether. Hence in so far as preservatives are concerned there is little danger of adulteration.

=Impure Raw Materials.=--If cheese be made of standard milk as provided for by the commissioners it must be made of pure, wholesome material. On the contrary, inasmuch as there is no official inspection of cheese factories, it is entirely possible through carelessness, ignorance, or design to use in the making of cheese milk which may itself be infected. Cheese made from such milk of course would carry the infection of the milk. This is a sort of adulteration which can only be excluded by careful sanitary inspection of cheese factories.

=Filled Cheese.=--Formerly there was a very considerable adulteration of cheese by manufacturing it from skimmed milk and supplying from an artificial source the necessary fat. Cottonseed oil, lard, and other edible oils are used for this purpose.

Composition of Filled Cheese (Circular No. 11, Bureau of Animal Industry).--Neutral lard is the principal fat which is substituted for milk fat in filled cheese. It is used to the extent of two or three pounds for every 100 pounds of skimmed milk. The principal objection to a filled cheese is not on account of its containing lard, which in itself is not unwholesome. But lard is an entirely different fat from milk fat, and differs in the character of the fermentation which takes place. The characteristic flavors and odors which are contributed by the milk fat in the cheese are entirely wanting, and the cheese is devoid of aroma and flavor and is nothing more than a mixture of casein with lard. Filled cheese is such a poor imitation of the genuine article that it can never have any very great vogue, and especially under the present law which requires it to be labeled and the payment of a tax. The law relating to filled cheese is found in the appendix.

A filled cheese which is on the market not properly stamped and duty paid in harmony with this Act of Congress is adulterated, and they who make and sell it are amenable to the law. The annual report of the Commissioner of Internal Revenue for the year ending June 30, 1905, shows that no receipts were obtained by the tax on filled cheese during that year. If any was made it was made surreptitiously and in defiance of the law.

From the above data it is seen that the manufacture and sale of filled cheese in the United States is almost a thing of the past and this form of adulteration, assuming that the law is thoroughly executed, is not now likely to be often met with.

=Cottage Cheese.=--Cottage cheese is a term applied to a product which is usually only a raw material of cheese. It is the fresh, precipitated, and unripe milk product, above described as used in cheese making. It is a highly nutritious and very palatable product, usually prepared at home and not suitable for keeping or transportation. It is often made from sour milk in which the casein is coagulated by the natural development of lactic acid. The sour milk is placed in a cloth bag and the whey allowed to escape by gravitation. The final portion of the whey may be forced out by pressure. The residue, when properly seasoned with salt or in any way to suit the taste of the consumer, is very palatable. Cream is often added to this residue which increases the normal amount of fat which it contains.

COMPARATIVE COMPOSITION OF AMERICAN AND EDAM CHEESE.

The chemical composition of some of the principal varieties of cheese are shown in the following table:

WATER. ASH. FAT. PROTEIN. Percent. Percent. Percent. Percent.

American cheese, 27.5 4.1 32.5 28.38 Edam cheese, 36.34 4.24 31.17 22.28

The data show that cheese is essentially a nitrogenous and fat food, containing only small quantities of carbohydrates, and therefore it is not a complete ration. It is a ration, however, which is complementary to a highly starchy diet such as rice or maize bread or potatoes. Bread and cheese or potatoes and cheese or rice and cheese, therefore, make a well balanced diet, highly nutritious, easily digestible, and quite palatable.

=Manufacture of American Cheeses.=--The large cheeses which are principally found upon the American market may be said, in general, to resemble the Cheddar type, although the calling of these cheeses by the name “Cheddar” is misleading, and to that extent a misbranding of the product.

There are two common methods of making these cheeses which are in vogue in the United States, namely, the “stirred curd” or “granular” method and, second, the Cheddar method. (Bulletin 104, Department of Agriculture of Pennsylvania, 1902.) The latter one is the more extensively used. The second product does not differ essentially in character from the first, though the latter method, it is claimed, gives a more solid cheese and one of more uniform character and with a slightly less content of moisture. Since the Cheddar method has practically come into sole use, displacing the first method, a description of the Cheddar method alone will be sufficient to illustrate the method of making large cheeses which are now so common on the American market and which have such a well merited reputation. The process is divided into eight parts: First, coagulating the milk; second, cutting the curd; third, heating the curd; fourth, removing the whey; fifth, cheddaring the curd; sixth, milling the curd; seventh, salting and pressing the curd; eighth, curing the cheese.

Rennet.--As has been said in the description of cheese making, the material which is most useful in the precipitation of the curd is rennet. The rennet is the secretion of the stomach of various animals, that of the calf being most highly priced for cheese making. The fourth stomach of the animal is the one which is used in the manufacture of rennet. The aqueous extract made from these stomachs contains a ferment which has the property of coagulating casein in a very high degree. One part of good rennet preparation from healthy stomachs of calves will coagulate 1000 parts of milk. In former days rennet was freshly made and used at the factories. At the present time it is largely prepared on a commercial scale and sold to the cheese maker. It is highly important that the rennet used in cheese making should be of the best quality, as an inferior grade gives a bad taste and color to the cheese. Just as in the manufacture of fermented beverages and making of bread the character of the yeast is a dominant factor in the nature of the finished product, so it is even to a greater degree in the case of rennet. Those who purchase the rennet already made should therefore be certain it is of a quality to give the desired character to the cheese. The greater the amount of milk fat in milk the larger the proportion of rennet, since the milk fat protects to some extent the casein from the action of the ferment. Experience has shown also that during the summer the rennet acts more readily upon the milk, probably due to the higher temperature. Care should be taken to avoid the use of any excess of rennet, since anything more than the amount necessary to conduct the coagulation is apt to add an unpleasant flavor to the cheese. The curd also in such cases is less cohesive and makes a tougher and drier product which does not lend itself so readily to the ripening process. For this reason the rennet which is to be used should always be tested in small quantities of milk beforehand in order that the proper proportion to be used may be known so that the process in a large way may be conducted with certainty and not by guess. (“British Dairy Farming,” by Jas. Long.)

Rennet is sometimes treated with borax to preserve it during transit. In such cases the borax may not all be removed by the whey and is consequently found in ripened cheese. Its introduction in this way should be avoided.

Coagulating the Milk by Rennet Extract.--This process is often termed by the cheese makers “setting the milk with rennet.” The milk which is used for the purpose of cheese making should be, in the technical language of the cheese maker, “ripe,” that is, containing a sufficient quantity of lactic acid. The principal method of producing the proper amount of lactic acid in milk is by keeping it warm, namely, at a temperature of about 84 degrees. At this temperature the most favorable conditions exist in milk for the rapid growth of the lactic acid ferments. If the natural ferments which produce lactic acid are not in sufficient quantity in the original milk it is better, rather than to wait too long a time, to start the development of the lactic acid by adding an artificial ferment. Lactic ferments are specially prepared for this purpose, or some previously ripened milk may be added to the mass. This is called a “starter.” From two to five pounds of “starter” are usually required for each one hundred pounds of milk. The degree of ripening is ascertained by measuring the quantity of lactic acid present. The proper condition of the milk is tested by means of a rennet preparation and if the milk will coagulate, when thus tested, in about one minute or a little more it is an indication that a sufficient amount of acid has been developed to add the rennet for the proper coagulation of the milk. It is important to have the milk in just the right condition in order that the proper operations in cheese making may go on uniformly. Care must be taken, however, not to have too much lactic acid in the milk. For instance, 0.2 of one percent is too great, and such a milk is very liable to give trouble in subsequent operations. In the curding of milk by rennet the temperature should be kept between 82 and 86 degrees. The amount of rennet extract, of course, varies with its character and strength, and this is best determined by the cheese maker’s experimenting in order that the proper quantity to be added to the great mass of milk may be known beforehand. A sufficient quantity of rennet extract should be used to curdle the milk in fifteen or twenty minutes for a quick-curing cheese, and in thirty to forty minutes for a slow-curing cheese. The rennet extracts in common use are added at the rate of from one-half to five ounces for 1000 pounds of milk. Before adding, the extract should be diluted with from 20 to 40 times its volume of water at a temperature of from 85 to 90 degrees. The rennet thus diluted acts with uniformity on the milk, preventing the production of curd of a lumpy character. Previous to adding the rennet extract the mass of milk is thoroughly stirred in order to mix the fat therewith and the dilute rennet added evenly and slowly with constant stirring which is continued for several minutes. A gentle stirring of the surface of the milk should be continued until the curd is at least half formed, in order that the fat may not separate. After the stirring is finished, a cloth is placed over the top of the vat to keep the surface of the milk from cooling, and the milk is then left undisturbed until the coagulation is complete. The coagulation goes on gradually until the whole mass of milk is one solid coagulum produced by the changing of casein into paracasein.

Cutting the Curd.--In order that the whey may be separated it is necessary that the curd be cut into pieces. The smaller the pieces of curd, the more rapidly will the whey escape. As soon as the curd is formed it shows a tendency to contract and this tends to force out the whey. By cutting the extent of the surface from which the whey can exude is amplified and the rapidity of the process is enormously increased. The time at which the curd is to be cut is one of great importance and is determined by the skill

and experience of the cheese maker. If the curd is cut when it is too soft there may be large loss of fat and a decreased yield of cheese. If the curd is too hard the whey is more difficultly removed and the quality of the cheeses is not so fine. The following test is used to determine when the curd is in the right condition to cut. The end of the index finger is inserted obliquely into the curd half an inch or more and then slowly raised toward the surface. If the curd breaks apart with a clean fracture without leaving any particles on the finger and the whey which exudes from the broken surface is clear and not milky it shows the proper time has come for cutting. Specially devised knives are used for cutting the curd, which leave it in small cubes of about one-half inch surface. Skill in the use of the cutting knife is important and can only be acquired by proper experience.

Heating the Curd.--As soon as the curd is cut the whey begins to go out of it and the curd settles to the bottom of the vat, the whey being of a higher specific gravity than the curd. After the pieces of curd sink to the bottom the surface easily reunites and, when broken apart, additional fat is lost. As soon, therefore, as the curd is cut the whole mass is kept in gentle motion by hand stirring or with a wire basket designed for the purpose, care being taken to avoid breaking or comminuting the cubes. When properly stirred the whey appears clear and is free of small particles of curd.

The curd contracts and hardens during this process, and soon reaches a condition when the surface does not adhere so readily. The vat should be kept warm during the process of separation of the whey, the temperature being raised to about 90 degrees and finally, toward the last, to 98 degrees, about blood heat.

Separating the Curd.--The precipitated curd is left in contact with the whey for some time, and during this period some of the lactic acid in the whey unites with the paracasein. The setting of the curd is finished when a small mass which has been squeezed in the hand to remove the whey is pressed against a bar of iron heated to little short of redness, and it is found that there is left, adhering to the iron, fine silky threads. These threads are formed by the compound of lactic acid and paracasein, and the more of this compound there is the longer will the strings be. When the curd shows by the hot iron test strings one-eighth inch long it is an index that the time has arrived for the separation of the curd from the whey.

Gathering the Curd.--After the whey is removed the cubes of curd are left in the bottom of the vat until they mat or pack together, a process which is technically known as cheddaring. The curd is sometimes removed from the vat and placed on a special apparatus for this purpose called a curd-sink. When the curd has matted together, forming a solid mass, it is cut into blocks 8 × 8 × 12 inches. These blocks are turned in the vat in order to facilitate the removal of more whey. The blocks of curd are carefully placed, one over the other until they form a large mass.

The process of solidifying or cheddaring accomplishes two purposes:

First, the whey is expelled to a considerable extent and, second, the lactic acid unites with more of the curd, changing not only its chemical composition but also its physical state from a spongy, tough, rubber-like consistence, with a high water content, to a mass having a smooth, velvety appearance and feeling, and a soft, somewhat plastic consistency.

Milling the Curd.--This process consists in cutting the lumps of curd into small pieces in order to introduce the salt and to handle it more readily when it is to be placed into hoops for pressing. This process is done by special mills which avoid, in so far as possible, the loss of fat.

Salting and Pressing.--Salt is added for several purposes, chiefly for flavoring, but it also has other uses. It aids in removing the whey,--it hardens the curd and it checks or retards the formation of lactic acid. Excessive salting, however, is injurious. From 2½■ to 3 pounds of salt should be added to the curd made from 1000 pounds of milk. Before putting in the press the curd is cooled to a temperature of about 80 degrees, and after putting into the mold it is subjected to pressure to give it a proper form, rather than to remove the whey which is practically all gone by this time. If the whey has not been properly removed before the cheese goes into the press it is almost impossible to get it out then. The pressure should be uniform and continued for at least twenty-four hours. If a screw is used the pressure should be light at first and gradually increased. After the cheese has been in the press about an hour it is removed, turned, a cloth adjusted about it, and the entire surface wiped carefully with a cloth wrung out of hot water.

The sizes in which American cheeses are made depends largely upon the market, the more common size being 15 inches in diameter, and the cheese weighs from 60 to 65 pounds. There is also a very large manufacture of cheese seven inches in diameter, known as “Young Americas” and weighing only from 8 to 10 pounds.

Curing.--The higher the temperature to which cheese is exposed in curing the more rapid the curing process will take place, but the poorer the quality of the cheese. Experience has shown that a low temperature, 55 degrees F. or even less, gives much better results, although it requires a greater length of time. If cured at a higher temperature the fat is apt to exude, and will not be evenly distributed in the cheese. It is, therefore, more profitable, as well as better for the consumer, to cure at low temperatures, producing a superior quality with less loss of moisture and a cheese which sells for a better price.

Moisture in the Curing Cellar.--The cellar in which the curing takes place should contain air with a proper degree of moisture. The relative percentage of moisture in the air as compared with the total amount which it can hold should be from 65 to 75. This is determined by placing in the curing room a hygrometer which registers the degree of saturation.

=Qualities of American Cheese.=--The quality of cheeses is judged by (1) flavor, (2) body, (3) texture, (4) color, and (5) general appearance. In regard to flavor it is impossible to describe what is meant. Only the connoisseur can determine properly whether a cheese has a flavor which is sound, healthy, and indicative of the highest quality. The cheese flavor should be free from any admixture of other flavors. Cheese resembles butter in this respect, that it absorbs and then gives off foreign flavors with great facility. Therefore in the whole process of cheese making care must be exercised to exclude every odor or flavor of an undesirable character from the cheese house.

Flavor.--Under flavor also may be described taste, which should be of that biting, incisive character due to proper development of ripening and its attendant bacterial and enzymic products. The various foreign flavors in cheese may be due to the odor of cows or the stable or may suggest “rotten eggs,” or it may be the flavor of rancid butter due to the decomposition of butter fat in the cheese.

Body.--This is also a term which it is difficult to define. An American cheese is said to have a perfect body when it is solid, firm, and smooth in substance. This quality is ascertained by pressing the cheese between the fingers. When it does not press down evenly between the finger and thumb it is said technically to be “corky.” It is smooth when it feels velvety-like and is not harsh or gritty.

Texture.--The term texture applied to American cheese refers mainly to its compactness. It is nearly related to body. The texture may be fine and close or porous. The texture is perfect when a cut surface of the inside of the cheese presents to the eye a solid, compact, continuous appearance, free from breaks, holes, or lumps. Cheese should not show any visible or separated moisture or fat. The texture of American cheese should be smooth, free from breaks, and fairly hard. The bandage should be smooth and neat, extending over the edge on each end of the cheese about two inches.

Color.--A true and unadulterated cheese should have only the color of the milk from which it is made, and any other color incident to ripening which is usually green. Unfortunately cheeses of American origin are often artificially colored. An over-deep yellowish or reddish tint, therefore, should be regarded as a mark of inferiority. Artificially colored cheese should not rank as high on the market as that of a natural tint, which is much more pleasing to the eye and much less objectionable to the æsthetic taste. Color is often added to conceal inferiority in the milk used.

The sides of the cheese should be straight and of uniform height all around.

The following scale of points is used in judging cheese, according to the above qualities: Flavor, 45 to 50; texture, 30 to 35; color, 10 to 15; general appearance, 5 to 15.

=Cream Cheese.=--This is a soft cheese which is rapidly growing in popularity. It is made from rich milk or milk and cream mixed together. It resembles in general Neufchatel, but it is richer in butter fat and is put up in a different form. The temperature of the room in which the cheese is made is quite important. It should be kept as nearly as possible at 75 degrees. The milk is first warmed to 70 degrees and run through a separator by means of which the cream is taken out, together with one-half the volume of milk. This makes either dilute cream or very rich milk, as you may choose to call it. The cream is heated to 84 degrees and about four or five ounces of rennet extract added per thousand pounds. The rennet is carefully and gradually stirred into the mixture, using about fifteen minutes for the addition. The mass is then allowed to remain at rest until whey is seen around the sides. The whey is then removed by draining, the resulting curd pressed and mixed with about 3 percent of salt. The cheese is not subjected to a curing process. It is molded into flat, thin cakes about 3 by 4 inches, wrapped in parchment paper, and in this condition packed for shipment.

=Manufacture of Foreign Types of Cheese in the United States.=--The improvement of cheeses made in the United States by securing different forms of ferments and utilizing the best method of setting, pressing the curd, and ripening used in other countries is worthy of all encouragement. Unfortunately a disposition has arisen in our country of giving the names of foreign varieties to the domestic articles. Many fancy domestic cheeses are sold under strictly foreign names such as Cheddar, Stilton, Cheshire, Schweitzer, Limburger, Camembert, Brie, Roquefort, etc. In fact there seems to be no limitation upon the adoption of a name already identified with a distinct type and locality. Such a tendency is greatly to be regretted and perhaps it is only necessary to point out to our people the ethical offense which they are committing by such practices to secure their discontinuance. It is, however, a perfectly legitimate undertaking to import the ferments which produce the famous cheeses of the world and utilize them to the fullest extent in cheeses of American origin. This, however, should be done in such a way as to carefully avoid applying the name of the original article to the domestic product. Perhaps it would be no ethical offense or no very great offense to place upon the labels of the cheese products a statement that they are of the same type as the foreign product they imitate. This, however, should be an explanatory phrase and not a part of the label which attracts principal attention. It is far better that a manufacturer should adopt some local name which would become identified with his product, and thus become a valuable trade-mark. The attempt to pass domestic cheese under foreign names is an offense against good ethics and also against the law. It is nothing more nor less than misbranding, and cannot be justified even in the absence of a law forbidding it.

Success with Foreign Ferments.--Considerable success has attended the introduction of the foreign processes into the United States, together with the ferments which produce the cheeses abroad. The environment, however, cannot be imported and therefore the ferments may rapidly assimilate different properties under changed conditions, and the continued importation of fresh ferments may be necessary to preserve the type of cheese. Some of the principal types of foreign cheeses made in the United States are those which are mentioned above. A particularly excellent study has been made of the process of making a Camembert type of cheese in this country. (Bureau of Animal Industry, Bulletin 71, 1905.) This particular cheese is a type of Camembert which is made at the Storrs Agricultural Experiment Station of Connecticut. For these experiments a cheese maker familiar with the Camembert manufacture in France was secured. The method of making the cheese and also of separating the curd and ripening was as nearly as possible like that used in France. The style of the packages was the same, so that from external appearances it would be quite difficult to distinguish them from the genuine Camembert cheese of France. The success attending these experiments shows that it is possible to improve domestic cheeses by scientific effort in the direction of using the proper ferments. These soft cheeses made in Connecticut were of good quality and had something of the flavor and type of the Camembert itself, though it was not difficult for even a novice to distinguish the two varieties from one another.

These studies above referred to have resulted in a marked degree of progress in the knowledge of the real changes which take place in the ripening of cheeses. The officials in charge of the work differ somewhat with the author in respect to the character of the product, claiming that the making of Camembert cheese is not dependent upon uniform conditions obtained only in certain localities but rather on securing the proper cultures and conditions which are possible almost anywhere. The fact of the case is that the cheeses made at the Connecticut station are probably made under much more scientific conditions and much more rigid control than the real Camembert cheese made in France. The success which attended these efforts is only a proof of the statement made above that the introduction of these processes for making fancy cheeses in this country will doubtless result in the development of types of American origin of peculiar flavor and quality. Such cheeses when properly named and not confused with those of foreign origin will become quite as familiar and well known, both at home and abroad. (Bureau of Animal Industry, Bulletin 82, 1906.)

=Sage Cheese.=--The consumption of the variety of cheese known as sage cheese is not very large at the present time in the United States and is restricted to certain localities, yet it is rapidly growing in favor. Consumers who are accustomed to it are willing to pay a larger price for it than for ordinary cheese. Sage cheese is made exactly in the same manner as that described for the manufacture of Cheddar. The flavor of sage is imparted in three different ways, first, by adding the sage extract or tea to the milk; second, by adding the extract to the curd before salting; third, by adding the sage leaves to the curd before salting. The latter method is found to be the most satisfactory requiring the least amount of sage to give any definite flavor. Three ounces of sage leaves are found to be sufficient to flavor the curd from 1000 pounds of milk. The stems and impurities of the sage leaves are carefully removed and the leaves ground to a fine powder before mixing with the curd (Michigan Board of Agriculture, 1904).

=Principal Cheeses of England.=--The principal English cheeses are Stilton, Cheshire, Cheddar, double and single, Gloucester, Derby, and Leicester. According to Dr. Voelcker, the finest flavored cheese is Cheshire, which differs from any other in being made from milk which is perfectly sweet, and some authors think its peculiar aroma is due to this fact. On the contrary, the more general

opinion is that the best cheeses are made from milk slightly sour rather than that which is perfectly sweet.

Cheshire cheese is manufactured by mixing the evening milk, which is kept cool over night, with the morning milk, and then warming the mixture until the temperature is about 90 degrees. The proper quantity of rennet is added and when the cheese is to be extremely yellow also some annotto. After thoroughly mixing, the mass is left for nearly an hour, by which time the coagulation is completed. The next operation is the breaking down or cutting up of the fresh curd, and this is an important process. Upon the care which is exercised in doing this depends in a large measure the richness and quality of the finished product. When properly manipulated the whey which is separated will be of a greenish color and clear, while the proper combination of milk fat and casein which is secured in separating the whey will make a cheese of first class quality. The curd is so dense as to naturally separate from the whey by deposition, and the latter is thus drawn off by a stopcock properly placed in the vat. The curd is then placed upon a cloth stretched over lattice work in order that the separation of the whey may be complete. Finally before passing to the cheese house the curd is treated with eight ounces of salt to twenty pounds of curd. After the cheese is molded it is placed in a warm room for one or two days, and then taken to the press house where it is subjected to the usual pressure. The pressing process is continued by wrapping the cheese in dry cloths and subjecting to new pressure every day for five or six days. The cheese is then removed to the ripening cellar where it is turned two or three times a week. It is ripe and ready for consumption in less than one year. There are a great many variations from this method of making Cheshire cheese, but they all follow the same general plan.

Manufacture of Cheddar Cheese.--The cheese is made in various parts of England though chiefly in Somerset, the period of manufacture extending from April to November. Cheddar cheeses are made in large sizes varying from 60 to 100 pounds each. The temperature of precipitation for Cheddar cheese is somewhat less than for the Cheshire cheese, being about 80 degrees. Rennet is used solely in the coagulation, lactic acid not being liked for that purpose. In the making of Cheddar often some of the fat escapes in the whey and this is afterwards collected and made into butter. Two pounds of salt to 100 pounds of curd are used.

Derby cheese is a name applied to cheese made in Derby. The Cheddar system of making it is usually employed.

Gloster cheeses are made on the same plan as that of the Derby and do not need any further description.

Leicester cheese is a variety of cheese which is very popular and made chiefly in the county of Leicester. The coagulation of Leicester cheese is made at a little lower temperature than that previously described, varying from 76 to 84 degrees. The curd is allowed to stand for about one-half hour before it is broken up and the whey separated. The best manufacturers of cheese disapprove of the use of artificial coloring and it may be said that eventually it is pretty certain that all cheese makers will come to the same conclusion. The use of coloring matter in cheese, even of annotto, adds nothing to its richness, and tends to deceive the customer into thinking that the milk employed was richer in cream than it really was. The Leicester cheeses are small in size compared with Cheddar. About eleven pounds of milk are used to make an ordinary cheese.

Stilton cheese is probably the most familiar and highly prized of all English varieties. It is not always to be obtained, and many imitations of Stilton are made and bear its name. The name it bears is from the name of the town where it was first, and is now, made. It is a cheese which has been known for about a century and a quarter. It is principally made between March and September and solely from the milk of cows fed on natural pasture, that is, for the finest variety. The use of artificial food for the cows is at once detected in a change for the worse in the character of the cheese. At first the rennet employed was made from the stomachs of lambs instead of cows and in the olden times the cheeses were not considered to be sufficiently mellow and ripe until they were two years old and exhibited spots of green in the interior.

The most approved modern process of manufacture is mixing the morning and evening milk and bringing it to a temperature of 79 degrees. Rennet is then added and the mass allowed to stand for about an hour and a half. The curd is removed into cloths set in frames for the purpose of allowing the whey to separate. Usually about an hour is allowed for the natural separation. The cloths are then tightened and brought closer together to produce slight pressure and placed in a cheese tub, several of them together, where they are allowed to remain for twelve hours. Usually a longer time is allowed before the curd is cut up. The salt is added in proportion of one pound to 60 pounds of fresh curd. The curd is then placed in tin cylinders with perforated sides, the cylinder being 12 inches deep and 12 inches in diameter, and put in a room at about 65 degrees to favor the separation of the whey which requires from six to seven days. The cheeses are then removed from the cylinders, brought into proper shape by a knife and wrapped with strong cotton cloth and allowed to remain for twelve days longer when they are removed to the drying room and kept at 65 degrees. During this process the original curd placed in the cell loses about one-half its weight so that ten pounds of curd in

the end make five pounds of cheese. A very common method also is to make cheese twice a day from morning milk and evening milk separately. Extra cream is often added in making Stilton cheese, only whole milk or milk and added cream being used. The principal point to be considered with curing is the regulation of the temperature.

Other varieties of cheese which are known in England are mostly named from the localities where they are produced and partake in general of the character of cheeses already described. These are Lancastershire, Wensleydale, skimmed milk cheese, butter milk cheese, potato cheese, and various forms of soft cheese or those used without being allowed to ripen for any length of time.

=Varieties of Cheese Made in France.=--There is a general idea that France is pre-eminently a cheese making country and this is true in so far as the making of certain brands of cheese which have international reputations is concerned. France, however, according to statistics, imports a larger quantity of cheese than she exports though probably the value of her exports is greater than the imports because of the high character and price of the exported articles.

Manufacture of Camembert.--The first cheese of this variety was made in 1791 by Marie Fontaine on a farm in the community of Camembert, near Vimontiers. The period of manufacture of Camembert cheese extends from March to September. It is made from whole cow's milk from which none of the cream has been extracted. The rennet is added at the temperature at which the milk comes from the cow as nearly as possible and the milk is artificially heated, the morning and evening milk being mixed, to this temperature. After the addition of rennet the milk is gently stirred for two or three minutes, a wooden cover placed over the pan, and left for five or six hours. The curd is sufficiently set when touched with the finger it does not adhere thereto. The curd is removed from the pan by a spoon and put into cylindrical metal molds open at the end and from these molds the whey is allowed to escape. It requires about two liters of milk to make one cheese. The whey is allowed to drain for about two days. After that time the mold is turned, a little fine white salt placed upon the top and allowed to drain for another day. After about 48 hours the cheeses are taken from the molds and salted. They are then placed in the drying room upon racks covered with straw. The drying room must be well ventilated and the air which is blown in for ventilation must be strained to be free of dust and insects. Care is taken also to exclude the sunlight, as this is very injurious to the proper development and ripening of cheese. The cheese remains in the dryer from 20 to 25 days. The ripening cellar is the next point to which the cheese is removed, and this cellar is kept as nearly as possible at 50 degrees F. The cheeses remain in the ripening cellar about 30 days, during which time they are frequently turned and carefully watched. The progress of the fermentation which takes place in the cheese is indicated by its appearance. In modern times the manufacture of Camembert cheese is continued practically throughout the whole year, but the artificially ripened cheese, that is, made during the winter by the aid of artificial heat, does not compare in quality with the product which is naturally ripened during the summer months. The manufacture of Camembert cheese has extended to a considerable distance from the original village, but it is all made in that part of France.

Emmenthaler Cheese.--Emmenthaler cheese is a variety of Swiss cheese of the same type as Gruyère. It is sometimes called the "cart-wheel" cheese on account of its immense size. These cheeses are sometimes three or four feet in diameter and of a disk-like shape, something like a wooden wheel sawed out of a round tree. It is a cheese which was originally made in Switzerland, although the manufacture of it has spread over into that part of France bordering Switzerland. It has the general character of Swiss cheese in texture, also in composition and nutritive value.

Brie Cheese.--This is one of the most famous of French cheeses. It is made in the form of a round flat mass about 16 inches in diameter for the grande Brie and 12 inches in diameter for the petite Brie. The thickness of the cheese is about one inch. The method of preparation is not very greatly different from that of cheeses in general. During the curing process, as in the case of Camembert, mould develops, especially on the outside of the cheese, and the change which goes on in the interior breaks down the casein, forming a creamy mass of a strong, piquant flavor. The mould which grows upon the outside of Brie cheese gives it a strong odor which reminds one of decomposition. Brie cheese might be said to resemble in general properties the Camembert variety of cheese.

Roquefort cheese is a very popular cheese made in France from sheep's milk. When properly ripened it shows a green mould. It is made in a particular way at Roquefort, and according to König has the following composition:

Water, 36.85 percent Fat, 30.61 „ Proteids, 25.25 „ Lactic acid, 1.90 „ Ash, 5.39 „

Port Du Salut.--This variety of cheese has a most deserving popularity, not only upon the Continent but in the United States. It is, however, not so generally known in this country as the Roquefort and Camembert varieties. It was long manufactured by a secret

process by the Trappist monks of Bricquebec in the Department of Manche.

The secret of the manufacture of this variety of cheese is guarded with the same jealousy by the monks as is the secret of making the chartreuse liqueur. Port Du Salut is always put up in very small packages of cylindrical form, flat, and about one inch in thickness. The cheese has a number of holes, in which it resembles the Swiss cheese. Its flesh, however, is mellow, and does not have the toughness nor solidity which characterizes the flesh of Swiss cheese. Although the monks' secret has been well guarded the general method of its manufacture has been described ("Cheese and Cheese Making," by Jas. Long and John Benson). The milk is brought to a temperature of 86 degrees F., and is treated with rennet in such a way as to separate the curd in about one-half hour. The separation of whey is secured in the usual manner, first, by allowing broken curd to stand, and afterwards by pressure. A peculiar form of pressure is said to be used by the monks,--a number of screws are placed side by side on a beam and a number of cheeses may be pressed at the same time. The pressure is applied solely by the hands and so is not very severe. After pressure the cheeses are placed in a ripening cellar, which is kept at about 54 degrees F. Care is taken in the ripening that the cheese does not become too dry.

Pont L'Evêque cheese is well known upon the Continent, especially in France where it is made. It takes its name from the village where the manufacture is carried on, which is not very far from Havre. The cheese is usually put up in a square or oblong package about one inch in thickness and of a size weighing about one pound. It has a tough crust and may be kept for some time after it is ripe with safety. The milk is set at a temperature of 88 degrees and a sufficient amount of rennet added to produce precipitation of the curd in about fifteen minutes.

When the curd is stiff enough to be cut and removed it is placed upon a mat made of rye straw through which the whey is allowed to filter. As the whey runs off the curd becomes tougher and the mat is brought together in such a way as to exert gentle pressure. This separation of the whey is continued until the curd can be placed in metal molds which vary in size according to the size of the intended cheeses. The cheese is ripened at a temperature of about 58 degrees in a humid cellar so as not to lose too much water.

Gervais cheese belongs strictly to the family of fancy cheese, being made of a mixture of milk and cream. It is produced in large quantities in France and finds almost an exclusive domestic market. It is named for its manufacturer, M. Gervais. The mixture is set at a very low temperature, about 65 degrees. The rennet which is used is diluted with water and added in small quantities so that the curd does not separate for eight or ten hours. The whey is separated in a cloth bag and under very gentle pressure. The cheeses are usually sold in only a partially ripe state and the cheese combines the flavor of both cheese and cream.

Bondon cheese is another cheese which is made largely in the region of Rouen. The size of the cheese is usually very small, from seven to nine being made from a gallon of milk. The method of manufacture is more like that of Gervais and differs from it chiefly in being made solely from milk instead of a mixture of milk and cream.

Limburger Cheese.--Limburger cheese is one of the most famous of the different varieties of foreign cheese, chiefly because of its bad odor. This odor is due to specific forms of ferments introduced during the ripening process. Generally Limburger cheese is made from pure milk, but occasionally skimmed or partially skimmed milk is used. The milk is set at rather a high temperature, from 92 to 100 degrees. After the coagulation has taken place the curd is broken into pieces the size of a hen's egg and allowed to settle to the bottom of the kettle as the whey separates. In England a copper kettle is usually employed for the testing vessel. After the whey has separated the curd is taken out and placed in rectangular molds with perforated bottoms, then laid on tables so that the remaining portion of the whey may drain off. The molds are turned from time to time to promote the separation of the whey and to make the cheeses keep their form. The cheeses are next placed in rows on a flat table with thin pieces of boards between them and subjected to light pressure. During this time they are salted by applying salt externally and rubbing the surface at frequent intervals for three or four days. The salt dissolves and permeates the mass. During the salting and pressing the cheeses are kept at a uniform temperature of about 60 degrees. The curing takes place in cellars, well ventilated but very moist, at a temperature of about 60 degrees. As the cheeses ripen they grow soft. The curd takes on its characteristic greasy appearance at the time of the ripening, becoming, at first, a yellow and then a reddish yellow. The softening begins on the outside and proceeds toward the center and the cheese is considered to be marketable when one-fourth of it has taken on its characteristic texture. The softening of Limburger cheese is due to a ferment which breaks down into a soft mass the casein or paracasein of which the cheese is largely composed. By using the same kind of ferments and by following the same process, imitations of Limburger cheese are made in the United States and other countries. These imitations, however, never equal the original in the character of the product nor in flavor or taste, and should not bear the name of the real article.

COMPOSITION OF LIMBURGER CHEESE.

Water, 35.7 percent Fat, 34.2 „ Casein products, 24.2 „ Milk sugar and undetermined, 3.0 „ Ash, 2.9 „

Limburger cheese was first made in the Province of Lüttick in Belgium. It has, however, come to be considered chiefly as of German production. The chief cause of the putrefactive fermentation which takes place in Limburger cheese is the extremely moist condition in which it is kept. For this purpose the atmosphere of the ripening cellar should be almost saturated with aqueous vapor, containing at least 95 percent of its maximum degree of saturation. This moist atmosphere, together with the low temperature at which the curing takes place, keeps the cheese soft and promotes the putrifactive ferments. Under these conditions the surface soon begins to get shiny and soft and changes from white to a reddish yellow. This change makes its way to the center, converting the harsh curd to a soft condition. The time required for this softening of the cheese is from four to six weeks. (“Cheese Making,” by John W. Decker.)

Edam Cheese.--Edam cheese is one of the most famous of the cheeses of Holland. It is made at the town of Edam, situated on the Zuyder Zee, about twelve miles northeast of Amsterdam. The milk from which Edam cheese is made should be properly acidified as has already been described. The coagulation takes place and the curd is separated much in the same manner as is used in the manufacture of Cheddar cheese. The curd is held for a time in the vat in a granular condition in order to develop greater acidity and until it will string one-half inch or one inch on the hot iron already described. It is then ready for the mold. The molds are of such a character as to give the cheese a spherical shape about six inches in diameter. Each cheese weighs about four pounds. It has a perfectly solid texture and its flavor is something like that of old Cheddar, except that it is a little more salty and somewhat harder. It is cured at a temperature of about 60 degrees and at a humidity of about 80 degrees. The curing period is somewhat longer than for most cheeses, lasting about eight or ten months and even a year. A slow curing is particularly necessary in the production of Edam cheese.

Coating with Paraffine.--In the curing of cheese sometimes it is coated with paraffine to avoid loss of weight. Coating with paraffine does not necessarily interfere with the character of the cheese, though it is probable that it must interfere in some way with the normal ferments. Paraffine is wholly indigestible and may produce injurious effects if swallowed with the cheese. (“Farmers’ Bulletins,” Nos. 186-190.)

=Fancy Cheeses.=--There is a large number of cheeses made in which cream enters as a prominent part. It is difficult to give these any particular name and the term “fancy cheese” has been applied to this form of cheese as a whole. They are usually put up in small packages or little pots and thus form an article of diet quite distinct from the large press cheese of commerce. In fact they are intended more for condimental purposes and to be eaten in something of the same manner as butter rather than cheese. These cheeses usually are sold for a much higher price and, therefore, can be regarded more as a luxury than as a regular article of diet.

It might be well to mention some of the more particular varieties of these fancy cheeses.

Gruyère.--Gruyère is a cheese made in Switzerland, where it is much prized and from where it is sent to the various parts of the world. It is a pressed cheese and is rather of a larger size than the fancy cheeses already described, and it is difficult to say whether or not it should find a place among them.

Parmesan.--Parmesan is a variety of cheese made in Italy. It is about the same size as Gruyère and thus has an intermediate place between the large pressed cheeses of commerce and the fancy cheeses above mentioned.

Gorgonzola cheese is a very familiar cheese made in Italy and belongs to the same class as the two preceding ones. It is in one sense a fancy cheese and yet is made in such quantities as to belong rather to the commercial variety.

=Bacterial Activity in Cheese.=--Modern science has led to the conclusion that the ripening of cheese is due principally to bacterial activity. The changes which take place in the chemical and physical properties of cheese materials, the flavor and aroma which are developed, the production of mould and other growths are marks of the activity of organisms of different character, living and unorganized. Due credit must be given to the enzymic (unorganized) action in these processes and the enzymes are not regarded as living organisms but, on the other hand, as catalytic agents inducing chemical changes similar to those produced in starch by the action of diastase. The peculiar flavors of cheeses which are found in different kinds have been ascribed in late years almost exclusively to the character of bacterial activity. This assumption is perhaps correct, but it must not be forgotten in this connection

that the same species of bacteria, in changed environments, does not always produce the same results. The activities of bacteria are peculiarly sensitive to the environment, such as change of temperature, physical conditions of different kinds, locality, and other factors of a complex nature, making up the total conditions in which the organisms live. For this reason the attempts to produce peculiar cheeses which belong in particular localities in other localities have not been gustatorily even if technically successful. It is true that cheeses may be made of the types mentioned, having some of the general characteristics but lacking that indescribable something which after all gives true character. Just as it is impossible to make a Rhine wine in California or a Bordeaux wine in New York so is it impossible to make a Cheddar cheese in Ohio or a Camembert cheese in Connecticut.

=Number of Bacteria.=--The number of bacteria, per gram, which appear in cheese varies according to the age of the cheese, conditions under which it is made, temperature, etc. The usual number of bacteria in one gram of cheese varies from five hundred thousand to nearly one hundred million (21st Annual Report of the Wisconsin Agricultural Experiment Station).

Ageing does not seem to increase the number of organisms, since it has been found by some observers that the maximum number present in cheese is found at the time it is taken from the press. It is difficult also to properly sample a cheese for the number of bacteria, since they are unequally distributed in different parts thereof, and the trier, by means of which the sample is secured, may show largely differing numbers in different parts of the same cheese. During the process of curing, especially if the curing be at a high temperature, the number of organisms decreases. At first the decrease is very rapid and then becomes slower as the cheese becomes riper. The decrease in the number of bacteria when the temperature of curing is raised is somewhat contrary to expectations. It has been found that when a cheese is taken from cold storage, say at 24 degrees F., and placed in a temperature of 60 degrees F., the decline in the number of bacteria is always greater than when the cheese is retained at the lower temperature. This may be due to the fact that bacteria which have been developed at a low may lose their vitality at a higher temperature. On the contrary, the development of flavor does not seem to depend upon the number of organisms since the peculiar flavor of cheese is more rapidly developed at the higher temperature, provided it be not too high, although this be attended with a diminution in the number of organisms. Evidently the conditions which favor the metabolic activities of organisms also favor their destruction, since when they have performed their functions they undergo natural disintegration. The character of cheese is such that when it is once formed there is no more opportunity given for a rapid proliferation of the organisms.

It may be found, however, that the development of bacterial life is not the sole or perhaps not the dominant factor in the development of flavors and aromas in cheeses but that this process is due very largely to the enzymic activities obtained from the rennet and which pre-exist in the milk.

=Chemical Changes Which Take Place During the Ripening of the Cheese.=--_Loss of Weight._--During the process of ripening of cheese there is considerable loss of weight, amounting to from 15 to 20 percent of the total weight of the fresh product. This loss is due chiefly to the evaporation of water, while in the fermentation which takes place volatile bodies are formed which also escape with the water. For instance, any free gas, either carbon dioxid, hydrogen, or nitrogen, which is produced will escape, likewise any alcohol which is formed will at least partially volatilize. There may be also a slight loss due to mechanical attrition, but that is not of any consequence. Owing to the loss of water some of the constituents which may diminish in actual quantity have their percentages proportionately increased. These changes are illustrated by the following analytical data:

MILK WATER. PROTEIN. FAT. SUGAR. ASH. Fresh cheese, 40.42 24.80 28 1.65 5.43 In the dry substance, ... 41.62 46.99 .... Same cheese one year old, 33.12 27.35 31.70 2.96 4.87 In the dry substance, ... 40.89 47.40 ....

The quantity of water which is lost in part depends upon the temperature of the store house and the dryness of the air. The loss of water should not be too great, otherwise the cheese would be dry and the ripening process would not go on in a proper manner. In some of the processes which take place during the ripening of cheese water is formed. If, therefore, there is no loss of weight during the process of ripening, the ripened cheese would have more water than the fresh cheese and this would impair the quality of the product. The loss of a certain part of water, namely, from 15 to 20 percent must be regarded as an advantage in the production of cheese.

Changes in the Protein.--The most important chemical changes, from a digestive point of view, which take place in the cheese are those which the protein undergoes. This protein substance consists chiefly of casein and undergoes profound alteration due to enzymic action during the process of ripening. The casein which when dry naturally forms a leathery, tough material changes into a more soluble and softer product, and during this change there are produced aromas and flavors which add much to the value of the cheese for edible purposes.

The character of the coagulation of the cheese originally has much to do with the general changes which the product undergoes during fermentation. The cheese makers for this reason must pay special attention to the rennet which they employ in the production of the precipitate. One of the most important of the changes which the casein undergoes is that which results in the production of ammonia. This indicates a complete decomposition of the protein substance, at least in part, so that the total amount of protein which is lost as such may reach as high as 25 or 30 percent of that present in the original cheese. There are also produced notable quantities of lucin and other nitrogenous compounds soluble in alcohol. In general it may be said that the changes in the nitrogen constituents of cheese are extremely helpful to digestion. Not only is the protein of ripened cheese more soluble but even the parts which remain unchanged as far as the protein constituent is concerned are so affected by the action of fermentation as to render them more readily subject to the action of the digestive ferments in the alimentary canal. There is a popular superstition that the use of cheese at the end of a meal helps to digest the other food which has given rise to the adage "Cheese, thou mighty elf, digesting all things but thyself." There is a base of scientific truth in this expression since in ripe cheese the enzymes remain still in an active form and when taken into the stomach must necessarily exercise an influence of considerable magnitude upon the process of digestion. The custom, therefore, which is so universal, of finishing a dinner with a bit of cheese is evidently based upon sound physiological as well as gastronomical principles.

Changes in the Fat.--The chemical changes which the fat undergoes in the process of ripening the cheese are also of considerable importance. It is claimed by some authors that additional fat is produced from the casein during the process of ripening, which is the cause of the lardy appearance of some cheeses. Many observers have found in ripened cheese a larger percentage of fat than that which was noticed in the fresh cheese. This apparent increase, however, may be due to analytical error, since in the fresh cheese the fat becomes entangled with highly insoluble caseous matter and is difficult of extraction, whereas after the ripening of the cheese and degradation and breaking up of the caseous tissues the fat is much more readily extracted. While it is not impossible that fat should be formed by the fermentation of the casein it does not seem that it is probable.

In examinations which were made of fresh and ripened cheese of the variety known as Roquefort there was found in the dry substance of the fresh cheese 40.80 percent of protein and 53.91 percent of fat. In the same cheese after it was quite old there was found in the dry substance 37.78 percent of protein and 56.14 percent of fat. These data serve to bear out the theory that fat is formed from the protein. On the contrary, it must be remembered that in the fermentation of the protein a number of volatile bodies are formed, especially ammonia, and thus the diminution in the percentage of protein is probably due to the loss of volatile bodies, and the increase in the quantity of fat is therefore a relative one, probably, and not absolute. There is no doubt, however, of the fact that the quantity or character of the fat does change considerably during the process of ripening. There is no reason for supposing that the fat alone of all the contents of cheese escapes enzymic action. It is profoundly changed in its character by the fermentations to which it is subjected, and this change, while it unsuits the fat for butter, may probably make it more palatable and desirable in cheese.

=Digestibility of Cheese.=--Reference has already been made to the fact that in the ripening of cheese the protein of the milk, consisting principally of casein, undergoes certain changes which apparently, at least, increase its digestibility. I use the word "apparent" because the flavor and aromas which are produced in the ripening of a cheese act as condimental substances and thus naturally excite the glands which secrete the digestive enzymes to greater activity. Therefore the increased digestibility may be due in part to the increased activity of the digestive ferments as above described rather than to the changes in the casein itself. It must be admitted, however, that these changes during ripening tend to make the casein more granular, softer, and to convert it into compounds more easily acted upon, and are thus favorable to increased digestibility. Experimental studies have shown that in a well ripened American cheese of the Cheddar type 93 percent of the protein present in the cheese and 95 percent of the fat are digested. Artificial digestion experiments have also shown that the pancreas ferments have much more effect upon cheese digestion than the peptic, showing that the cheese is more acted upon in the small intestines, perhaps, than in the stomach. Attention must also be paid to idiosyncrasies in these cases, as there are many people who find it impossible to digest cheese in any form. The eating of larger quantities than are necessary also tends to derange the digestive organs. A well ripened cheese, therefore, should be eaten rather as a condimental substance than as an actual food product, though its value as a food is fully attested. ("Farmers' Bulletin," No. 162.)

=Effect of Cold Storage on the Curing of Cheese.=--Attention has been called, in the description of different methods of making varieties of cheeses, to the ordinary temperature at which cheeses are cured. In European countries these temperatures are maintained without the use of artificial means. In the United States it is difficult to maintain a very low temperature in summer time

without the use of artificial refrigerators. Experimental studies have determined that when the temperature of ripening or storage is reduced to a considerable extent below that usually specified for the standard varieties of cheese the quality of the cheese is superior although the time for storage or ripening is very much prolonged. The artificial curing of cheese has been secured at as low a temperature as 40 degrees. There is also a less loss of weight in cheese cured at this low temperature. A cheese which was cured at 40 degrees when examined by experts scored a mark of 92.4 while the same cheese ripened at 60 degrees scored 95. Another test of a cheese cured at 40 degrees scored 95.7 while the same cheese cured at 50 degrees was marked 94.2 and the cheese cured at 60 degrees 91.7.

=Preparations of Casein.=--Properly in connection with cheese preparations may be mentioned those products which are of a food value, procured from casein itself. The precipitated casein is prepared for the market by washing, drying, and grinding to a fine powder, and is then sometimes called protein flour. Sanose is a mixture consisting of about 80 percent of casein and 20 percent of the protein derived from the white of egg. The addition of the white of egg enables the casein to remain in suspension when mixed with water and thus causes the preparation to resemble milk. Casein preparations of this form are practically insoluble in water and, therefore, are not perhaps of the best forms of nitrogenous food for invalids. To avoid this insolubility the casein has been combined with alkalies and the preparations are known as _nutrose_ and _eucasein_. Plasma is also a preparation of casein with alkalies which are added in sufficient quantities to give 7 percent of ash. These caseinates, as they are sometimes called, that is, combinations of casein with alkalies, are soluble in water and are found to be to a certain extent digestible and nutritive preparations. Casumen and sanatogen are other preparations of casein with alkalies or glycero-phosphate. Wonderful claims are made by manufacturers concerning the digestibility and nutritive properties of these preparations. It is doubtful, however, if they have much greater value, if any, than natural casein in the form of milk or as ripened in cheese. Preparations of this kind usually appeal strongly to those who suffer from digestive disorders and therefore high-sounding names, which are given to practically the same preparations, lead the seeker after health often to try the same substance under a dozen different appellations. These remarks are not made for the purpose of decrying in any way the merits which these preparations may have but only to illustrate a very marked tendency on the part of many people to attribute extreme virtues to ordinary food substances which are sold under attractive and sometimes deceptive names and whose properties and virtues are advertised in an expert manner. Because a food substance consists almost wholly of pure protein is no indication whatever of its exceptionally high food value. Protein is only one form of food and a concentrated ration of protein in any of these forms is just as likely to do harm as good. For emergency rations, for economy in transportation, and for certain diseased conditions of the digestive organs these preparations are undoubtedly valuable, but they have little claim upon the general public in a state of health as staple articles of diet. They are much more nutritive than the extracts of beef and other meats which have obtained a vogue wholly out of proportion to their dietetic or medicinal value. (“Foods and Principles of Dietetics,” by Robert Hutchinson.)

PART V.

CEREAL FOODS.

BARLEY (GENUS _Hordeum_).

In the United States barley is not used to any extent as human food. It has all the nutritive properties of the common cereals and may be considered as a food product, although its chief use is in the making of fermented beverages which will be described in full in the second volume.

Barley is cultivated chiefly in the northern and western portions of the United States and is similar to the oat in this respect, that when the grain is threshed by the ordinary process the first layer of chaff is not separated, and, therefore, it goes into the market unhulled. There are varieties of naked barley which are not much cultivated. The cultivated varieties (_Hordeum sativum_ Pers.) belong practically to one species, although there are very many different varieties grown.

The character of barley best suited to malting will be discussed in the second volume.

Acreage and Yield of Barley.--The area planted to barley in the United States and other statistical data relating thereto for the year 1906 are as follows:

Acreage, 6,323,757 Yield per acre, 28.3 bushels Total production, 178,916,484 „ Price per bushel, 41.5 cents Value of crop, 74,235,997 dollars

=Composition of a Typical Unhulled Barley.=--From a comparative study of a number of samples of American barley the following numbers are regarded as typical of the composition of the unhulled barley grown in the United States:

Weight of 100 kernels, 4.53 grams Moisture, 10.85 percent Protein, 11.00 „ Ether extract, 2.25 „ Crude fiber, 3.85 „ Ash, 2.50 „ Starch and sugar, etc., 69.55 „

The important points brought out in the above data are that the percentage of fiber in the unhulled barley is less than one-half that of the unhulled oat, as stated further on, while the percentage of ether extract is only about one-half that of the unhulled oat, and the protein is also decidedly less than in the whole oat.

As has been stated, barley is not very generally used in this country for human food, but is used in this and other countries as an ingredient of soup.

[Illustration: FIG. 22.--BARLEY STARCH. × 200.--(_Bureau of Chemistry._)]

=Protein of Barley.=--The following protein compounds are found in barley in proportionate weight to the total weight of the seed:

Leucosin, 0.30 percent Hordein, 4.00 „ Edestin, 1.95 „ Proteose, 1.95 „ Insoluble protein, 4.50 „

As seen from the above table the most important of the soluble proteins is hordein, which in quantity is almost equal to the insoluble protein of the barley grain. The starch granules of barley are recognized by their distinctive shape and size, as revealed by the microscope. A typical microphotographic view of barley starch is shown in Fig. 22.

BUCKWHEAT (_Polygonum fagopyrum_ L.).

=Buckwheat= is usually classed with the cereals, but botanically it does not belong to the order of true grasses to which the cereals belong.

Buckwheat is commonly grown in many parts of the United States, and its seed is highly prized for bread and cake making purposes. The buckwheat is ground and the outer black tough hull separated, and the flour is used chiefly for making hot breakfast cakes which are much prized throughout the country. Properly ground buckwheat flour has a more or less dark tint, due to fine particles of the outer envelope which escape the bolting process.

Acreage and Yield of Buckwheat.--This crop is not grown in many states. New York, Pennsylvania, and Michigan produce the largest quantities. The statistical data for buckwheat grown in the United States in 1906 are as follows:

Acreage, 789,208 Yield per acre, 18.6 bushels Production, 14,641,937 „ Price per bushel, 59.6 cents Total value, 8,727,443 dollars

=Composition of Buckwheat Flour.=--The composition of finely bolted buckwheat flour is as follows:

Moisture, 11.89 percent Protein, 8.75 „ Ether extract, 1.58 „ Ash, 1.85 „ Fiber, .52 „ Starch and sugar, 75.41 „ Calories per gram, 3,854

The above is the composition of a white flour more finely ground and bolted than is advisable for palatable purposes. In the grinding of the above flour the germ which contains a greater part of ether extract is eliminated and also a large quantity of the bodies rich in protein. The composition of a less highly refined flour and one which is more palatable and more nutritious is given in the following data:

Moisture, 11.19 percent Protein, 9.81 „ Ether extract, 2.33 „ Ash, 1.53 „ Fiber, .73 „ Starch and sugar, 74.41 „ Calories per gram, 3,954

=Milling Process.=--In the preparation of the so-called highest grade of buckwheat flour, that is, that which is most carefully ground and thoroughly bolted, the process employed is as follows: During the process of milling the buckwheat grains pass to a receiving separator which removes all the coarse particles, stones, straws, etc., by means of a series of sieves. At the same time any dust which they contain is blown out by a current of air. The sifted grains pass next to the scouring machines, in which they are thoroughly scoured, cleaned, and polished. From these machines the grains pass to a separator containing magnets, by means of which any pieces of metal, in the form of nails, screws, pieces of wire, etc., are removed.

The grains next pass through a steam dryer for removing the greater portion of the water employed for the scouring. As soon as they are dry they are again treated to a blast of air, which removes any dirt, dust, or light particles which may have been detached during the process of drying. The grains next pass to the shelling rolls, where the greater part of the outer hulls is removed. This process is accomplished by means of an apparatus which is called a sieve scalper. After the separation of the outer hulls the residue of the material passes to a drying chamber, where the moisture is reduced to about 10 percent, thus insuring the keeping qualities of the flour. After drying the grains are ready for the rolls. After entering the rolls the process is practically the same as that which is employed in milling wheat, consisting of a series of breaks and reductions, with the attendant bolting and grading, and this process is prolonged until the flour is practically removed from the feed or middlings. The sifting cloths used in the bolting of buckwheat flour are somewhat coarser than those for wheat, and this allows some of the dark particles of the inner hulls to pass into the flour, which gives it a dark color on baking. It is quite possible to make a buckwheat flour as white as that from wheat, but in this country the public taste requires a darker product, so that the white flour does not readily sell. The requisite degree of darkness is secured by using bolting cloths which will allow a part of the inner hulls (middlings) to pass into the flour. Two grades of flour are generally produced--a whiter one in which finer cloths are used, and a darker flour made by using coarser bolting cloths, allowing larger quantities of middlings to pass through. The outer hulls which are first removed are used for fuel, although from their composition it is seen that they contain a large quantity of carbohydrates and might be very profitably used in connection with some highly nitrogenous food, such as cottonseed meal or flaxseed meal for feeding cattle. The middlings are used principally as cattle food, and especially by dairymen.

The above process, while it makes a white and fine-looking flour, is not to be compared with the meal made in the old-fashioned way of grinding between stones and separating the principal part of the outer hull by bolting. This old-fashioned flour is more nutritious, that is, it contains more fat and protein, has a greater fuel value, or in other words has a greater number of calories and makes a much more palatable cake than the fine modern flour.

=Buckwheat Cakes.=--Buckwheat cakes are prepared from batter made by mixing buckwheat flour into a paste of the proper consistency, seeding it with yeast, and allowing it to remain in a moderately warm place until fermentation takes place. The proteins of buckwheat have some agglutinating power, and thus, when treated as above, make a cake capable of a considerable degree of aeration. Baking powders are often used as a substitute for yeast and permit of preparation in a few minutes instead of waiting for the fermentation above mentioned. The product made in this way cannot be considered so palatable or nutritious as the old-fashioned product. The batter is baked on a smooth hot iron or soapstone, polished and kept bright in order to prevent the sticking of the cake. The proper polishing of the iron is a better means of preventing sticking than greasing. The batter is poured over the smooth iron and is of a consistency to flatten out without help and to form a film over the baking iron, which produces a cake about one-fourth of an inch in thickness. The cake is to be turned as soon as the side in contact with the iron is brown. It is evident that in this baking process there can be no very profound change in the starch granules, but this does not appear to materially interfere with the digestibility of the product. Buckwheat cakes are eaten hot, usually with butter and sirup. Maple sirup, sorghum sirup, or cane sirup in a pure state are highly prized for use with buckwheat cakes. These sirups are both condimental and nutritious. Mixed sirups made of glucose, melted brown sugar, or molasses, or mixtures of all these bodies are more commonly furnished to the consumer than the pure sirup mentioned above. Honey is also used very extensively as a condimental flavor for cakes of this kind.

=Adulterations.=--There is probably no bread or cake making material which is subjected to more extensive adulteration than buckwheat flour. Much of what is sold as buckwheat flour may be regarded as imitations of that substance. Mixtures of rye flour, Indian corn flour, wheat flour, and other ground cereals are used as a substitute for buckwheat. There can be no objection from the hygienic point of view to such substitutes but the use of these mixtures under the name of buckwheat can be regarded in no other light than as an unpardonable fraud.

=Detection of Adulterations.=--There is rarely any mineral adulteration practiced with buckwheat flour and if so it is easily detected by incineration. Any content of ash, unless baking powder has been used, above 2 percent may be regarded with suspicion as indicating an admixture of some mineral substance. The cereal flours used for adulteration are readily detected by the microscope in the hands of an experienced observer. The field of the microscope has only to be compared with the microscopic appearance of genuine buckwheat starch in order to detect the added substance.

=Buckwheat Starch.=--The microscopic appearance of buckwheat starch is shown in the accompanying figure. The granules of buckwheat starch are very characteristic. They consist of chains or groups of more or less angular granules with a well defined

nucleus, and without rings or with very faint rings. The contour of buckwheat starch is more angular than that of any other common cereal with exception of maize and rice, and it is this and the relative size which enable the observer to distinguish it from other starches. The size of the granules is quite uniform, varying usually only from 10 to 15 microns[23] in diameter. In so far as the angular appearance is concerned the granules of buckwheat starch have a general resemblance to that of maize and rice and oats, but a comparison under the microscope of the three starches reveals lines of distinction which with a little practice would prevent the observer from drawing a false conclusion.

[23] A micron is one thousandth of a millimeter.

[Illustration: FIG. 23.--BUCKWHEAT STARCH. × 200.--(_Courtesy of Bureau of Chemistry._)]

INDIAN CORN (_Zea mays_).

Next to wheat the most important cereal used as a human food in the United States is Indian corn. According to the magnitude of the crop, Indian corn is the leading cereal of the country. Statistical data on the production of Indian corn in the United States during 1906 are given in the following table:

Acreage, 96,737,581 Yield per acre, 30.3 bushels Production, 2,927,416,091 „ Value per bushel, 39.9 cents Total value, 1,166,626,479 dollars

=Indian corn= is universally employed as food throughout all parts of the country, but more especially in the South, where the daily dietary is rarely complete without one or more meals in which Indian corn is served in some form or other. Although it is grown much more extensively in the North than in the South, it is not so generally used as human food. Indian corn grows in all kinds of soil and produces, under favorable conditions, large yields in all parts of the country. It is the most important agricultural crop of many states, namely, Indiana, Illinois, Iowa, Missouri, and Kansas. It is planted in the late winter and spring in different parts of the country. The planting season varies from January in Florida to June in Maine and Minnesota and the earlier varieties will mature in 120 days.

=Maize= is a crop which requires an abundance of rainfall and a high temperature during the growing season. Maize is planted in rows about three and one-half feet apart and in hills of about the same distance apart, or it may be drilled between the rows so that one stalk grows a distance of about from nine inches to a foot from its fellows. It requires constant cultivation during the early period of its growth and a careful preparation of the seed bed. Good farmers give from four to seven cultivations to the growing crop. The field must be kept free of weeds and in good tilth to secure the best results.

Many hundreds of analyses of the maize kernel have been made, but a combination of them all in the following data may be regarded as typical of the Indian corn grown in this country.

Weight of 100 kernels, 38 grams Moisture, 10.75 percent Ether extract, 4.25 „ Protein, 10.00 „ Fiber, 1.75 „ Ash, 1.50 „ Starch and sugar, etc., 71.75 „

The consideration of the above data shows that Indian corn is a ration in which the protein is rather low. In other words, the ratio of protein to the carbohydrates and fat is rather large. It is a food product which is particularly well suited to furnish heat and energy and support a high degree of muscular exertion. For this reason it is a food product which is particularly well adapted to men engaged in hard manual labor.

=Varieties.=--There are many distinct varieties of Indian corn. Sturtevant has published a description of several hundred. These varieties are classified under various subspecies. The polymorphic species, _Zea mays_, according to Sturtevant, can be divided into a number of groups which, on account of their well defined and persistent characters, may be considered as presenting specific claims and may properly receive specific nomenclature. The grouping adopted is founded upon the internal structure of the kernel for cultivated varieties, and the presence of a husk to the kernel in the assumed aboriginal form. Hence Sturtevant offers the names _Zea tunicata_ for the husk-kernel forms, _Zea everta_ for the popcorn, _Zea indurata_ for the flint corns, _Zea indentata_ for the dent corns, _Zea amylacea_ for the soft corns, and _Zea saccharata_ for the sweet corns.

[Illustration: FIG. 24.--SECTION OF RAW POPCORN. × 150.--(_Courtesy of Bureau of Chemistry._) Shows cells with the small angular starch grains closely packed together within them.]

Argument in favor of the specific claims for these groups is based primarily on the convenience thus attained; secondarily, on the absence or rarity of intermediate or connecting forms, so far as present data extend, and also on the antiquity of the separation. It seems almost certain that in the order of evolution (excluding from consideration the puzzling sweet corn group) progress has been from the pops, through the flints and the dents, to the softs. Certainly the soft corns in some of their varieties present a kernel that is larger, softer, and less fitted to the struggle with natural conditions than is the kernel from any of the other groups. Yet soft corns are the prevailing form in the mummy burials of Peru and of our Southwestern states. The popcorn, on the contrary, has stronger regerminative powers than have the other groups, is better fitted to contend against natural vicissitudes, and is the kind that has been reported as found growing wild in Mexico under the name of Coyote corn, _Zea canina_ Watts.

Some of these subdivisions may not be accepted by botanists, but they are convenient for purposes of description. The principal field varieties which are grown are the flint corn, _Zea indurata_, and the dent corn, _Zea indentata_.

POPCORN.

This variety of maize is used very largely in the United States as a delicacy, and with sugar and cream as a dessert. It is a hard, small-grained variety which has the property, when heated, of exploding with a very great enlargement of the starch grain, producing a soft and very delicate edible material which is highly prized.

[Illustration: FIG. 25.--SECTION OF POPCORN IN FIRST STAGE OF POPPING, SHOWING PARTIALLY EXPANDED STARCH GRAINS AND RUPTURED CELL WALLS. × 150.--(_Courtesy of Bureau of Chemistry._)]

In the raw popcorn the starch grains are packed together very closely within the cells. When popping begins there is an expanding of the starch grains, producing a cavity nearly circular in form in each grain. This causes a rupturing of the cell walls, though fragments are plainly visible in the early stages. In the fully expanded or popped kernel the starch grains have expanded until each is about half or two-thirds as large as the original cells of the endosperm. The cell walls in this stage are practically obliterated as far as detecting in a section is concerned. The exploding of the starch grains is influenced by the water content of the kernel. It must not be too wet nor too dry; about 10 or 12 percent is the proper content of moisture. These changes are beautifully shown in the accompanying microphotographs, Figs. 24, 25, and 26, by Mr. Howard, of the Bureau of Chemistry.

[Illustration: FIG. 26.--SECTION OF FULLY POPPED POPCORN. × 150.--(_Courtesy of Bureau of Chemistry._) The fully expanded starch grains are nearly half as large as the original cells in which they were contained.]

SWEET CORN.

This is a variety of maize which develops a high sugar content and is eaten while the starch is yet soft, in other words, in an unripe state. It is a food product of immense importance in the United States, although almost unknown in Europe. The content of sugar varies from 5 to 8 percent in the fresh, soft kernel. The sugar which is present in the kernel rapidly disappears after the husking or removal from the stalk. In order to secure the maximum sweetness the corn should be cooked and eaten as soon as possible after removal from the stalk. Where it is not possible to do this it should be placed in cold storage after removal from the stalk and remain unhusked until it is ready for cooking. Green corn is universally eaten hot. It is usually cooked by boiling in water, although it may also be roasted before the fire. It has a high food value, and the composition of the grains of fresh, soft, green corn is shown in the following table:

Composition of Fresh Green Indian Corn:

Moisture, 73.00 percent Starch, 13.50 „ Sugars, 6.00 „ Protein, 5.00 „ Crude fiber, 1.20 „ Ash, .70 „ Fat, .60 „

=Maize Proteins.=--The proteins of maize are composed principally of two zeins. The two forms are differentiated by their behavior toward alcohol. The first form constitutes the zein soluble in alcohol and the second the zein insoluble in alcohol. There are two other proteins in maize existing in small quantities which have been named myosin and vitellin, respectively. There is also a third unnamed variety and small quantities of albumin.

=Variation in Maize, under Different Climatic Conditions.=--It is possible that most of the varieties and subvarieties of maize are simply the existing standard varieties modified by changing environments. There are certain conditions of climate, soil, and distribution of rainfall which tend to produce a large, starchy, soft grain, while other conditions tend to produce a small, hard grain richer in protein. The variations of importance are those of the carbohydrates and the protein, which are complementary, since as

the protein rises the carbohydrates fall in relative proportion. There is also a marked variation in the carbohydrates, due to variety and climatic conditions combined. It is, for instance, the increase of the sugar at the expense of the starch that produces the body known as sweet maize eaten in the green state, as already described. Even in the sweet variety the relative proportion of sugar varies in different localities and under different conditions of growth.

=Early Varieties.=--There are certain varieties of maize which are of especial value on account of their early maturation. This is a property extremely valuable in the sweet variety of maize or that eaten in the green state, since it is important to get these varieties into the market as early as possible and to continue them as long as possible. This is secured by planting the early variety at as early date as possible and planting later maturing varieties at intervals thereafter. By the selection of varieties of different periods of maturing it is possible in the climate of Washington to offer green corn from neighboring fields on the market from July until the advent of a killing frost which is usually the last of October or first of November. This gives a period of nearly four months during which the green corn may be delivered to the local market. Further south the period of supply is longer.

=Canned Corn.=--Immense quantities of green corn are grown for the purpose of canning in order to supply the market during the closed season. The canning industry for green corn is located chiefly in the north. In the eastern states the industry is of great importance, from Maryland to Maine. The northern-grown corns are often preferred as they are supposed to be sweeter and more palatable. In the central western states, northern Indiana, Michigan, Wisconsin, northern Illinois, and Iowa are the principal centers of the canning industry, although it is practised to a greater or less extent in almost all parts of the country.

=Adulterations of Canned Corn.=--Unfortunately in the canning process of corn additions have been made to the product which are of an objectionable nature. Chief among these is the use of bleaching agents such as sulfur in the form of burnt sulfur or of sulfite or bisulfite of soda or potash. These bleaching agents impart to the corn a white color which some consumers prefer, but at the expense of introducing a substance which must be regarded as deleterious to health. Still more objectionable is the practice of using saccharin instead of sugar as a sweetening agent. Saccharin is a coal tar product which has an intense, sweet taste, very persistent, and when used alone becomes disagreeable. A very small quantity of it is sufficient to impart a very sweet taste to the canned corn at a much less expense than could be secured by using the pure sugar. This form of adulteration is extremely reprehensible both because it deceives the consumer and adds a substance which by most hygienists is regarded as prejudicial to health. The bleaching agent and the artificial sweetener are wholly unnecessary. The manufacturers of sweet corn are expected to use the best and freshest and sweetest materials and cannot be excused for tampering with them in any way which either produces deception or injury to health.

Sugar added to make an ordinary corn taste like sweet corn is to be regarded as an adulteration unless its use is noted on the label.

Maize starch is also often added to sweet corn at the time of canning and this practice can only be regarded as an adulteration.

=Detection of Adulterations in Sweet Corn.=--_Test for Sulfurous Acid._--To about 25 grams of the sample (with the addition of water, if necessary) placed in a 200-c.c. Erlenmeyer flask, add some pure zinc and several cubic centimeters of hydrochloric acid. In the presence of sulfites, hydrogen sulfid will be generated and may be tested for with lead paper. Traces of metallic sulfids are occasionally present in vegetables, and by the above test will indicate sulfites. Hence positive results obtained by this method should be verified by the distillation method.[24] It is always advisable to make the quantitative determination of sulfites, owing to the danger that the test may be due to traces of sulfids. A trace is not to be considered sufficient as indicating either a bleaching agent or a preservative.

[24] U. S. Dept. Agr. Bureau of Chemistry, Circular No. 28, pp. 11-12.

Detection of Saccharin.[25]--Add from 25 to 40 c.c. of water to about 20 grams of the sample; macerate and strain through muslin; acidify with 2 c.c. of sulfuric acid (1 to 3) and extract with ether. Separate the ether layer, allow the ether to evaporate spontaneously, and take up the residue with water. If saccharin be present its presence will be indicated by the sweet taste imparted to the water. To confirm this test add from one to two grams of sodium hydroxid, and place the dish in an oil bath. Maintain the temperature of the oil at 250° C. for 20 minutes, when the saccharin will be converted into salicylic acid. After cooling and acidifying with sulfuric acid, extract in the usual way and test for salicylic acid. This test, of course, presupposes the absence of salicylic acid in the original sample. If salicylic acid is present in the original sample it must be removed before making the test for saccharin.

[25] _Ibid._, Bul. 65, p. 51.

[Illustration: FIG. 27.--INDIAN CORN STARCH. × 200.--(_Bureau of Chemistry._)]

=Starch of Indian Corn.=--Maize starch has characteristics which enable it to be easily detected by the microscope. The granules of this starch are of a more uniform size than those of wheat and vary from 20 to 30 microns in diameter. Occasionally very much smaller granules occur which probably are more of the original size and which have been arrested in growth by the ripening of the grain. The granules of maize starch are more or less polyhedral in form with round angles. The only common cereal starch which they can be mistaken for is rice, but they are generally larger than the granules of rice. Under the microscope with ordinary light they give only the faintest sign of rings but show in most cases a well developed hilum, which is at times star-shaped or like an irregular cross, while at other times it has the appearance of a circular depression. The maize starch granular is a type of the angular, as the wheat is of the sphere or spheroid form. The characteristic appearance of maize starch kernels is shown in the accompanying Fig. 27. Viewed with polarized light the starch grains of Indian corn present deep, well marked crosses, which divide each grain into four distinct parts as shown in Fig. 28. It is interesting to note that the angularity of maize starch is greatly influenced by the hardness of the kernels from which the grains are taken. The hard varieties, such as popcorn, have very angular grains while those from soft varieties have a great many almost spherical forms.

[Illustration: FIG. 28.--STARCH GRAINS OF INDIAN CORN, UNDER POLARIZED LIGHT. × 200.--(_Courtesy of Bureau of Chemistry._)]

=Maize Flour= (_Corn Meal_).--Formerly the maize kernel was ground between stones, bolted to remove the bran, and the maize flour or corn meal thus produced used directly as a human food. Modern milling operations have changed the method of producing maize flour so that not only is the outer bran removed but also, to a large extent, the germ itself, thus diminishing the quantity of fat in the prepared meal. This is notably true of the maize flour which is prepared for exportation. Leaving in the flour such a large quantity of fat tends to produce rancidity during shipment. To avoid any change of a deleterious nature which the flour may undergo during shipment, it is also frequently kiln-dried before being sent to foreign shores and even when intended for domestic consumption at points remote from the mill.

While this preparation of maize flour is doubtless important for transportation purposes, it impairs the palatability and nutritive value of the product. It is advisable to continue to have the maize flour prepared in the old-fashioned way and sent directly into consumption.

=Method of Preparation.=--One method of preparing the maize flour is as follows: The grains are broken into large pieces and dried with steam heat at a temperature of from 105° to 110° C. (221°-239° F.). The mass while still hot passes into a mill composed of two stones which revolve rapidly in opposite directions. The smaller portions of the meal, which have been reduced to a kind of gum by the high temperature, are separated by this process from the covering or the bran of the kernel. A small mass of the starchy matter leaves the mill in the form of small noodles, which are freed from any particles of bran by sifting. In this manner a mass is obtained which is quite free from fiber and fat.

The composition of maize meal prepared by the above process is as follows:

Moisture, 9.70 percent Protein, 12.68 „ Ether extract, 1.19 „ Ash, .60 „ Fiber, .35 „ Starch, sugar, and dextrin, 71.48 „

This method of preparing maize meal is not used to any extent in this country, but is said to be commonly employed in Germany.

=Composition of Maize Flour.=--The color of maize flour depends upon the color of the corn from which it is produced,--it may be white or yellow. The starch granules when heated in water to 62.5° C. swell up and become deformed, except a few, usually the small ones, which resist the action of water at that temperature. The starch granules of maize flour under polarized light present a black cross, very marked and very distinct when the field is obscured. When viewed under polarized light with a selenite plate the starch grains of maize are colored red with a green cross or reciprocally, and this coloration is very brilliant.

As has already been said, the composition of Indian corn meal made by the old-fashioned method of grinding and removing only the bran is practically that of the whole grain itself.

The composition of degerminated maize meal (Indian corn flour) is shown by the following average data:

Moisture, 12.57 percent Protein, 7.13 „ Ether extract, 1.33 „ Ash, .61 „ Fiber, .87 „ Starch and sugar, 78.36 „ Calories calculated on the moist meal, 3,837

The above data show that the refined Indian corn meal has lost more than three-fourths of its fat, a large portion of its mineral matter, and also a very considerable proportion of its protein, due to the separation of the bran which is extremely rich in protein and the germ which is rich both in oil and protein. A mere glance at the data shows that this refined Indian corn meal is much less nutritious than the natural meal in so far as its content of tissue-forming bodies and its faculty to furnish heat and energy are concerned. In other words, the calories are very much lower than in the natural corn meal. This is another reason for urging our people to return to the consumption of the old-fashioned material.

=The Adulteration of Indian Corn Meal.=--Owing to the cheapness of Indian corn in so far as is known there is no adulteration practiced. The refined Indian corn flour itself is sometimes used as an adulteration for buckwheat flour, wheat flour, and other cereal flours, but has not itself been subjected to adulteration.

=Corn Bread= (_Indian Corn Bread_).--Corn bread is a very common diet among all classes of people in the southern states and also to a considerable extent in the north.

Owing to the lack of agglutinating powers of the nitrogenous constituents of Indian corn flour, corn bread cannot be aerated or raised, as is the case with wheat bread. It is often eaten in an unleavened state. It may be partially leavened by the usual agent, namely, yeast or a chemical baking powder. Two varieties of bread are very commonly used, namely, that made of white flour or meal and that made of yellow. There is apparently no difference in the nutritive values of these two kinds. Some consumers prefer the white loaf and some the yellow.

=Composition of Indian Corn Bread.=--The composition of bread depends upon whether the whole grain flour is used from which only the coarse bran has been removed by bolting or whether the decorticated and degerminated meal is used. In the first case bread is made richer in fat and protein and in the second case richer in starch. In the bread will also be found the materials used in its preparation, namely, salt, lard or other fats, milk, yeast, or baking powder residues. The best bread is made from the freshly ground flour of the whole grain from which only the outer covering, namely, the coarse bran has been removed. As offered at many of our hotels and some private houses, corn bread has been so manipulated as to lose a large part of its palatability, without any compensating improvement of its nutritive properties.

OATS (GENUS _Avena_).

This cereal is an important food product, being used very largely in Europe, especially in Scotland, and also very extensively in this country as human food. The chief use of oats is for cattle food, especially for horses. It is extraordinarily rich in its nutritive constituents and, therefore, is prized highly as a food in the building and restoration of nitrogen tissues, such as the muscles. The variety in common cultivation is _Avena sativa_ L.

Oats are grown in almost every part of the United States, but chiefly in the northern and western portions. In the southern states the crop is planted in the late autumn or early winter. In the northern states it is chiefly a spring crop, being sown early in the spring as soon as the ground is in fair condition. The oat crop is one which requires a rather abundant and well-distributed rainfall. A spring drought is very detrimental to the growth of oats, much more so than wheat or rye. It is a crop which is well suited to be grown under irrigation.

There are many varieties of oats in cultivation, but in general characteristics they all correspond to one description. The husk adheres firmly to the grain, and when threshed the grain of a common variety of oat carries the first layer of husk or chaff with it. Oats, as bought in the market, therefore, consist not only of the kernel or grain but also of this outer, chaffy envelope. The magnitude of the crop in the United States is very great, but only an inconsiderable proportion of the whole is used for human food, and this chiefly in some form of oatmeal. The statistics of the crop grown in the United States during 1906 are given in the following table:

Acreage, 30,958,768 Yield per acre, bushels, 31.2 Total yield, bushels, 964,904,522 Price per bushel, cents, 31.7 Total value at farm, $306,292,978

=Ratio of Kernel to Hull.=--Numerous examinations of unhulled oats show that the average percentage of kernel to hull for 100 parts is as 73 to 27. In the oats grown in the western states the proportion of kernel is relatively higher and in the southern states lower.

In the analytical process if the hull or chaff is ground with the grain the proportion of fiber or crude cellulose is very considerably higher than in the class of cereals ground without the chaff. The mean composition of unhulled kernels of oats of American growth is represented by the following table:

Weight of 100 unhulled grains, 2.92 grams Moisture, 10.06 percent Protein, 12.15 „ Ether extract, 4.33 „ Crude fiber, 12.07 „ Ash, 3.46 „ Starch and sugar, 57.93 „

A study of the above data shows that the flour of unhulled oats is rich in fat, fiber, and ash. The large percentage of fiber and ash is due to a great degree to the composition of the hulls or chaff. The fat or oil comes chiefly from the germ.

=Composition of Hulled Oats.=--Inasmuch as the chaff is always separated from the oat flour when the latter is to be used for human food, the composition of the oat in the hulled state is of greater importance to the present purpose than in the unhulled condition. The means of 179 analyses show the hulled oats to have the following compositions:

Moisture, 6.93 percent Protein, 14.31 „ Ether extract, 8.14 „ Crude fiber, 1.38 „ Ash, 2.15 „ Starch and sugar, 67.09 „

The removal of the hulls, as is seen, and the partially dried condition of the grain in the above analysis increases the percentage of other ingredients. The protein and fat are especially large in quantity. Oatmeals may be regarded as the richest of the cereal flours, both in protein and in oil.

=The Protein of Oat Kernels.=--There are three principal products in the oat kernels characterized by their different degrees of solubility, namely, protein soluble in alcohol, protein soluble in dilute salt solution, and protein soluble in alkali. The protein soluble in alcohol constitutes about 1.25 percent of the whole grain, the protein soluble in dilute salt solution about 1.5 percent, and the protein soluble in alkali the remainder, viz., 11.25 percent. The protein of oats has very little agglutinating power and, therefore, oat flour is not suitable for making bread, or rather it is very little used for that purpose.

=Oat Products.=--As has been intimated before, the principal oat products, as far as food is concerned, are the various forms of oatmeal commonly classed as breakfast foods. These products are prepared in various forms of agglutination and physical texture but if made from genuine oats, as there is little cause for doubt, they have essentially the same composition and nutritive power. It is doubtful if there is any preparation of oatmeal any more nutritious or palatable than the plain oat grain properly cooked. The forms in which the oat products are offered to the public are perhaps more convenient for use and in some cases by reason of heating and preparation require less trouble, but otherwise they apparently have no advantage over the simple product.

The mean composition of a number of oat flour products is shown in the following table:

Moisture, 7.66 percent Protein, 15.48 „ Ether extract, 7.46 „ Crude fiber, 1.20 „ Ash, 1.29 „ Starch and sugar, 67.61 „

In the dry substance:

Protein, 16.77 percent Ether extract, 8.08 „ Crude fiber, 1.38 „ Ash, 1.94 „ Starch and sugar, 73.20 „ Calories, 4,875

It is evident from the above average analysis that the products examined are made from the whole kernel without the removal of the germ but with a very careful removal of the hull and bran. The composition of these products compares very favorably with the typical composition of the kernel itself. These data show the high nutritive value of these oat products, both in respect of fat and protein.

[Illustration: FIG. 29.--OAT STARCH. × 200.--(_Courtesy of Bureau of Chemistry._)]

=Adulterations.=--There are very few adulterations of oatmeal. Fortunately the price of this cereal is such that the admixture of other cereals would not be profitable. Doubtless such admixtures have often been made but evidently, from the examination of the products upon the open market, they are not very frequent. The characteristic appearance of oat starch is shown in Fig. 29.

Oat starch grains average about 10 microns in diameter. There are usually present some grains of somewhat oval shape, which assist in identifying oat products when present. The starch granules also have a tendency to agglutinate into masses of varying

size, as shown in the photograph.

=Detection of Adulterations.=--The adulteration of oatmeal with the flour of other cereals can easily be detected by the use of the microscope. Oat starch when highly magnified presents a peculiar cellular structure of pentagonal character which might be compared to the effect produced by grinding a large number of faces upon a precious stone. This peculiar appearance is caused by the tendency of the starch granules in oats to become compacted in large masses. The appearance of the separate granules and also the compact aggregate are shown in the figure on the preceding page. The large aggregated masses are of different sizes, ranging from .02 to 1.2 millimeters in length. These masses are usually broken up by grinding or pressure and, therefore, are not found in very great abundance in the commercial oatmeal. When separated into single granules these are found to be irregular in outline, due to the compression to which they have been subjected, more or less pentagonal in structure, and from .015 to .02 millimeter in diameter. The starch granules do not show any very marked characteristics under polarized light and have neither lines nor hilum. The above statements can easily be verified by any one who can operate an ordinary microscope, but before attempting to detect adulteration a careful examination of starch granules, prepared by the investigator himself, should be made.

RICE (_Oryza sativa_).

Rice is one of the most important food cereals. It furnishes a large part of the food of the inhabitants of China and Japan. It is a food rich in starch and poor in protein, and furnishes, therefore, heat and energy, and is well adapted for the nourishment of those engaged in hard labor or who undergo extreme physical exertion. The cultivation of rice is rapidly extending in the United States, especially in Louisiana and Texas. The statistical data relating to the rice crop for 1906 are as follows:

Acreage, 575,014 acres Production, 17,854,768 bushels Yield per acre, 31.1 „ Price per bushel, 90.3 cents Total value, 16,121,298 dollars

The adulteration of rice is confined to coating it with talc, paraffin, and glucose. The object of this treatment is to give a better appearance to the grain and to protect it from the ravages of insects. The use of indigestible substances such as talc and paraffin is scarcely justifiable. The starch granules of rice have distinctive properties which enable them to be readily recognized under the microscope, as shown in Fig. 30.

The rice starch grains are polygonal in form and have sharp angles. The grains vary in size from 2 to 10 microns, though the latter size is seldom reached, the most of the grains being about 6 microns. The hilum is seldom visible. The grains occur in the rice kernels mostly in groups of a considerable number of the individual grains forming starch masses of ovoid or angular form.

[Illustration: FIG. 30.--RICE STARCH. × 200.--(_Courtesy of Bureau of Chemistry._)]

RYE.

This is the source of the principal supply of bread in many European countries, but is not extensively used in the United States except among our citizens of foreign birth. It is also extensively used for making whisky. Rye belongs to the genus _Secale_. Only one species (_Secale cereale_ L.) is commonly cultivated, but this species has a great many different varieties or races. According to the time of sowing there are two great classes of rye, namely, that planted in the autumn or early winter and that planted in the early spring, generally known respectively as winter and spring rye. This is one of the hardiest of cereals, and grows well in all locations where wheat and other common cereals flourish. The area planted in rye in the United States in 1906 and the quantity harvested are given in the following table:

Acreage, 2,001,904 Yield per acre, 16.7 bushels Production, 33,374,833 „ Price per bushel, 58.9 cents Total value, 19,671,243 dollars

=Composition of Rye.=--From a study of many hundreds of analyses of rye of American origin the following table may be given as approximating the composition of a typical American rye:

Weight of 100 kernels, 2.50 grams Moisture, 10.50 percent Ether extract, 1.50 „ Protein, 12.25 „ Fiber, 2.10 „ Starch and sugar, 71.75 „ Ash, 1.90 „

[Illustration: FIG. 31.--RYE STARCH. × 200.--(_Courtesy of Bureau of Chemistry._)]

The percentage of moisture in American grown rye is usually less than that of European origin. The American rye, also, has smaller kernels as a rule than that of foreign growth. In the content of protein the American samples of rye are fully equivalent to those of foreign origin, and in their mean composition, except as noted above, do not differ greatly from that of standard varieties collected abroad.

=Protein of Rye.=--As is the case with other cereals more than one nitrogenous constituent exists in the rye. Three of the principal ones have been separated and named as follows: leucosin, gliadin, and edestin. Other proteins belonging to the globulin, albumin, and proteose family are also found in small proportions. The gliadin of rye resembles in its chemical and physical properties the gliadin of wheat. There is, however, in the rye no protein compound corresponding to the glutenin of wheat, and, therefore, rye flour does not form a gluten similar in quality to that of wheat, although it comes more nearly doing so than any other cereal. The gliadin of rye is soluble in alcohol, the leucosin of rye is soluble in water, and the edestin is soluble in a salt solution.

In a typical sample of American rye there will be found about 5.16 percent of gliadin, 2.27 percent of edestin and proteose, 0.55 percent of leucosin, and 3.14 percent of protein soluble in salt solution.

=Adulteration of Rye Flour.=--Rye flour is frequently adulterated by the admixture of flours of other cereals. Real rye flour is distinguished by the character of the starch granules, as shown in Fig. 31.

Rye starch grains are lenticular in form, and the largest grains are of about 50 microns diameter. They average somewhat larger than wheat starch grains and are characterized by many of the large grains having a fissure in the form of a slit, cross, or star, which is rare in wheat and barley. The rings and hilum are indistinctly seen in some of the grains.

=Rye Bread.=--This bread may be made leavened or unleavened, since the analogy in the property of its protein to that of wheat renders the leavening of rye bread somewhat more easy of accomplishment than that of the other cereals, with the exception of wheat.

Rye bread made of pure rye flour has a dark color, sometimes almost black. It is often baked long in advance of the time of eating and keeps well, is highly nutritious, and is the staple bread of many European countries.

A partial rye flour bread is made by mixing rye flour with other flours, such as wheat, barley, Indian corn, etc., and this is the kind which is commonly used in this country and in many portions of Europe where the light-colored breads are preferred to the dark.

The large consumption of bread made from rye and Indian corn indicates that even if the supply of wheat should become limited there is no reason to fear a famine of bread. It would be easy to substitute bread made wholly or in part of Indian corn and rye for that made wholly of wheat and thus to supply practically any demand for bread which the increasing population of the earth may make.

WHEAT (GENUS _Triticum_).

In respect of human nutrition wheat is the most important of the cereals. It is grown in the temperate regions of almost every country, but does not flourish in tropical or subtropical countries.

In the United States the wheat is divided in respect of the period of its growth into two great classes, namely, winter or fall planted wheat and spring or spring planted wheat. Winter wheat is usually planted from September to November and spring wheat from the last of March to the last of April.

In this country wheat is not cultivated, that is, there is no cultivation of the soil after seeding. The soil is, however, plowed and harrowed before planting. In the winter wheat regions the harvesting is in the month of June, though in the southern localities it comes somewhat earlier and in the more northern localities may extend into July. In the spring wheat regions the harvesting is from the last of July to the middle or end of August. The statistics of wheat grown in the United States during 1906 are as follows:

WINTER. SPRING. Acreage, 29,599,961 17,705,868 Yield per acre (bushels), 16.7 13.7 Total yield (bushels), 492,888,004 242,372,966 Total value at farm, $336,435,081 $153,897,679 Price per bushel (cents), 68.3 63.5

All the different varieties of wheat which are now known are cultivated. The simplest form, namely, the one grain wheat is the only one which grows wild, and the origin of the other varieties of wheat is unknown.

Botanists recognize three species, namely--Species 1, one grain wheat (_Triticum monococcum_ Lam.); species 2, Polish wheat (_Triticum polonicum_ L.); species 3, common wheat (_Triticum sativum_ Lam.). All of these species are distinct, especially the third one, of which the most valuable variety is the common wheat, _Triticum vulgare_ Vill.

The quality and properties of wheat depend more upon the environment in which it is grown than upon the species to which it belongs. There is perhaps no other field crop in which the environment, namely, condition of the soil, temperature, precipitation, etc., makes a greater difference than in wheat. In general, the environment and the species together produce two kinds of wheat as far as milling and bread making are concerned, namely, the soft or starchy wheat and the hard or glutinous wheat. In the first variety there is a larger percentage of starch in relation to the content or protein matter than in the second. Taking the wheat as a whole its average composition is shown in the following table:

Weight of 100 kernels, 3.85 grams Moisture, 10.60 percent Protein, 12.25 „ Ether extract, 1.75 „ Crude fiber, 2.40 „ Ash, 1.75 „ Carbohydrates other than crude fiber, 71.25 „ Dry gluten, 10.25 „ Moist gluten, 26.50 „

In regard to protein American wheat, as a rule, is quite equal to that of foreign origin. This is an important characteristic when it is remembered that both the milling and food value of a wheat depend largely upon the nitrogenous matter which is present. It must not be forgotten, however, that merely a good percentage of protein is not of itself a sure indication of the milling value of a wheat. The ratio of gluten to the other protein constituents in a wheat is not always constant, but it is the gluten content of a flour on which the bread making qualities chiefly depend.

=Gluten.=--The principal part of the protein in wheat is known as gluten. Gluten as such does not exist in the wheat but is formed when the pulverized wheat, that is, the wheat flour, is mixed with water by the union of two elements in the wheat, namely, gliadin, which is soluble in dilute alcohol and forms nearly half of the whole protein matter of the wheat kernel, and glutenin, a compound insoluble in water, dilute salt solutions, and dilute alcohol and which is quite as abundant as gliadin in the wheat kernel. In fact, the gliadin and the glutenin together make the whole of the protein, except a little over one per cent.

There are three other forms of protein, as pointed out by Osborne, in the wheat kernel, making altogether nearly 1½■ percent of total protein content. The average quantity of these compounds in the protein of wheat is as follows.

Constituents:

Globulin, 0.70 percent Albumin, 0.40 „ Proteose, 0.30 „ Gliadin, 4.25 „ Glutenin, 4.35 „ ----- 10.00

=Starch in the Wheat Kernel.=--The most abundant constituent of the wheat kernel is the starch. The appearance of wheat starch is shown in the figure. Wheat starch grains ordinarily show the rings and hilum in a few cases only under the most favorable conditions, though there are sometimes cases where the striations are quite distinct. The granules of starch vary greatly in size, being from 5 to 10 microns in diameter. There are, in fact, two kinds of granules in wheat starch, one having the appearance under the microscope of irregularly rounded particles in sections like a circular disk, and the other of elongated particles with a distinct hilum, as shown in Fig. 32. The appearance of the granules under polarized light is shown in Fig. 33.

Wheat starch is not very commonly used for commercial purposes but is highly prized for some things, especially in the sizing of textile fabrics. The germ in wheat is particularly rich in oil and the bran or outside covering in protein. The common idea that the bran is composed mostly of silicious matter is wholly erroneous. On the contrary the bran is a highly nutritious food, and the objection to it for human food is mostly of a mechanical nature.

=Adulterations.=--Wheat grains are never adulterated but they may sometimes contain dirt and foreign seeds, due to the growth of some body in connection with the wheat itself.

=Standards.=--Wheat, commercially, is sold under three standards, namely, one, two, three. The difference is an arbitrary one and not founded upon any chemical data but wholly upon the physical appearance, degree of moisture, and freedom from extraneous admixtures.

=Wheat Products.=--The principal product of wheat is flour. The milling process for wheat is highly interesting both from a chemical and technical point of view, but cannot be described in full in this manual. The old-fashioned milling of wheat, namely, pressing between stones and separation of the flour by bolting has been almost entirely superseded by the modern milling with metal rollers.

[Illustration: FIG. 32.--WHEAT STARCH. × 200.--(_Courtesy of Bureau of Chemistry._)]

Altogether nearly a hundred different products are made incident or final to the milling of wheat. Only those products, however, which are used for human food interest us at the present time.

=Chief Varieties of Flour.=--The highest grade of wheat flour is known usually by the term “patent”; a lower grade is known as “bakers’ flour” and a third as low grade flour. A barrel of flour weighs 196 pounds and requires about 258 pounds of wheat for its manufacture. The whole product from the 258.35 pounds of wheat is shown in the appended table.

In general it may be said that about 75 percent of the weight of the wheat is obtained as merchantable flour of some kind, about 60 to 70 percent being good grade or straight flour. About 24 percent of the weight of the wheat is obtained as cattle food and about 1 percent is lost during the process of manufacture.

PRODUCT. POUNDS. PERCENTAGE. Patent flour, 149.37 57.82 Bakers’ flour, 29.13 11.28 Low grade flour, 17.50 6.77 ------ ------ Total flour, 196.00 75.87 Bran, 45.56 17.64 Shorts, 9.80 3.79 Screenings, 4.99 1.93 Waste, 2.00 0.77 ------ ------ Total weight, 258.35 100.00

[Illustration: FIG. 33.--WHEAT STARCH UNDER POLARIZED LIGHT. × 200.--(_Courtesy of Bureau of Chemistry_).]

=Special Names of Flour.=--In addition to the classification above mentioned other names are used in many commercial senses for flour. These additional names are “family,” “red dog,” “blended,” gluten, etc. Many flours are also named after the name of the mill or locality or bear simply fanciful names.

Graham Flour.--This term was originally applied to the coarse, unbolted flour which was made by grinding the whole wheat. The name, therefore, should be applied to all flour made from well grained wheat, ground, and unbolted. Most of the flours however, which are sold nowadays as graham flours are produced by a more or less perfect bolting process. From the above it is seen that true graham flour will contain practically the same constituents as the wheat kernel itself and in the same proportion and have the same composition as wheat.

Entire Wheat Flour.--This name would naturally carry the idea of a flour corresponding to the graham flour above mentioned. It is, however, a misnamed trade-mark for a flour produced in a special manner which consists in the removal of the outer or purely branny covering of the grain. “Entire wheat” flour, therefore, contains all the ingredients of wheat grains, save those which are found in the outer branny covering.

Gluten Flour.--This is a name applied to a flour which is produced by removing the greater part of the starch from ordinary flour. It is especially recommended for the use of diabetic patients. Unfortunately, the name is very commonly applied to flours made from wheat containing a little higher percentage of protein than the ordinary and sometimes even to an ordinary wheat flour. Its use with such a product is purely fraudulent.

Mixed Flour.--The act of Congress of June 13, 1898, defines mixed flour and imposes a tax upon the manufacture, sale, importation, and exportation of that article. The maximum tax laid upon mixed flour is 4 cents on a barrel of 196 pounds. The total number of barrels of mixed flour returned for taxation for the fiscal year ending June 30, 1905, was 362; half barrels, 59,443; quarter barrels, 6,265; eighth barrels, 24,974. The total quantity of mixed flour returned for taxation during the year is 5,495,937 pounds. The above data show that the amount of mixed flour offered for sale is a very small part of the total flour manufactured in the United States. It may be that there is a great deal of flour mixed and sold in violation of the law since it is quite impossible in the inspection of the stores to supervise all the transactions of business deals in flour; especially is it believed that rye flour and buckwheat flour are often adulterated by mixing with them the flour of other cereals. This adulteration is not one which is at all injurious to health but is simply practiced for the purpose of making a rye or buckwheat flour look whiter or because the added flours are cheaper than the real rye or buckwheat.

=Properties Affecting the Commercial Value of Flour.=--Aside from its nutritive properties wheat flour has a commercial value depending upon its color and texture and upon the gluten which it contains. The character of gluten also varies largely in different varieties of wheat and in wheat grown in different localities. A chemical examination will not always tell the bread making properties of a flour, and the character of the bread itself depends often quite as much upon the skill of the baker as upon the flour which is used.

In cases where loaves are sold by weight, a flour with a high percentage of tenacious gluten is often preferred, since it permits of the forming of loaves containing a maximum percentage of water. With a flour rich in gluten it is not difficult to make a palatable loaf which does not bear any evidence of an excess of water, containing as much as 40 percent of moisture. The baking of bread is an art which is most successfully practiced by professionals, and the American method of home bread making does not always lead to the happiest results.

The ideal flour for bread making is one which contains a sufficient quantity of gluten to make a porous and spongy loaf, but not one which permits an excessive quantity of moisture to be incorporated in the loaf itself.

=Average Composition of Different Varieties of Flour.=--Analyses of a great number of samples of different varieties of flours lead to the following data, which may be accepted as a very close approximation of the average variety of different grades of flour offered upon the American market:

----------+--------+--------+--------+--------+ | | PRO- | PRO- | | | | TEIDS | TEIDS | | | MOIS- | N × | N × | MOIST | NAME OF FLOUR. | TURE. | 6.25. | 5.70. | GLUTEN.| ----------+--------+--------+--------+--------+ |_Perct._|_Perct._|_Perct._|_Perct._| Patent flour, | 12.77 | 10.55 | 9.62 | 25.97 | Bakers' and family flour,| 11.69 | 12.28 | 11.20 | 34.70 | Common market flour, | 12.28 | 10.18 | 9.28 | 24.55 | Miscellaneous flour, | 12.73 | 10.45 | 9.52 | 26.80 | Self-raising flour, | 11.45 | 9.75 | 8.89 | 26.97 | Gluten flour, | 12.99 | 13.30 | 12.13 | 39.68 | ----------+--------+--------+--------+--------+

[26] In the first of these columns the starch is calculated by difference, assuming the protein to be the quantity of nitrogen present multiplied by 6.25, and in the second column the figure is obtained in the same way, using 5.70 as the protein factor.

=Separation of Gluten.=--The character of a wheat flour, as has already been intimated, is measured largely by the quantity of gluten which it may contain. The separation of gluten may be accomplished by any one, even without a chemical training, by a little practice. It is, therefore, one of the tests for the value of a wheat flour which can be easily and generally applied. The principle of separation of the gluten rests upon the fact that when wheat flour is moistened and kneaded into a sticky mass it may be washed with pure water with constant kneading until nearly all the starch has been removed from the mass. Meanwhile only that portion of the protein is removed which is soluble in the water and the gluten which is formed by the process of kneading remains as a sticky mass. When this moist mass is kneaded and rolled until all the moisture is taken out of it that can be removed in this way, it may be weighed and the proportion of moist gluten in the sample determined. It may then be placed in an oven and dried, and then the proportion of dry gluten secured. The following method is one which is easily applied. Place 10 grams of the sample in a porcelain dish and moisten with from 6 to 7 cubic centimeters of water, knead, and allow to stand for an hour. Work into a ball, being careful that none of the material adheres to the dish. Holding the mass in the hand knead it in a slow stream of cold water until the starch and all soluble matter are washed out. Place the ball of gluten thus formed in cold water and allow to stand for one hour; remove from water, press as dry as possible between the hands, roll into a ball, and weigh in a flat-bottomed dish. After weighing, place the ball of moist gluten in the drying oven for twenty hours; cool and weigh.

[Illustration: FIG. 34.--KEDZIE'S FARINOMETER SHOWING THE PARTS.--(_Bulletin 13, U. S. Dept. of Agriculture._)]

=Gluten Tester.=--A simple test for determining the approximate percentage of gluten in flour may be used, based upon the principle that the viscosity of dough is a measure of its practical gluten content. The name applied to a gluten tester is farinometer.

A convenient form of farinometer devised by Kedzie is shown in the accompanying figure. It is patterned somewhat upon the plan of Jago's viscometer. The instrument is shown in parts in Fig. 34. The instrument as in use is exhibited in Fig. 35. Parts shown in

Fig. 34 are as follows: No. 1 is the stand or support of the parts. No. 2 is the cap of No. 1, and discloses the half-inch opening (half closed by the slide) through which the dough is forced by the pressure of the rod No. 4. The slide by which this opening is closed is plainly shown; also the socket for holding No. 3. No. 3 is a brass tube 3 inches high and 1 inch internal diameter, with a small knob to fit into the notched opening in the side of the socket seen in No. 2, to hold No. 3 firmly in place. No. 4 is a steel rod ¹■/■■ inch in diameter and 12 inches long, with a thin brass cap 1 inch in diameter, beveled slightly so that the front edge fills the barrel of No. 3 without friction, and is yet dough-tight. Near the top the rod is marked into inch spaces.

In using the farinometer two points are considered:

1. The water-absorbing power of a flour, or the percentage of water it will take up to form a dough of a certain consistency.

2. The viscosity of such dough, or its resistance to change of form under a uniform force; _e. g._, the length of time in seconds required to force a cylinder of dough 1 inch high through a hole one-half inch in diameter under the pressure of a vertical steel rod 13 inches long and weighing 2½■ pounds avoirdupois.

[Illustration: FIG. 35.--KEDZIE'S FARINOMETER IN USE.--(_Bulletin 13, U. S. Dept. of Agriculture._)]

=Bleaching of Flour.=--At the present time flour is extensively bleached for the purpose of making an inferior article resemble a superior one. By this means a greater percentage of the flour produced can be rated as of first quality. Ozone and oxids of nitrogen developed by electrical discharges are the principal bleaching agents employed. Bleached flour should bear a label indicating to the purchaser the character of the manipulation to which it has been subjected.

=Adulterations of Flour.=--The adulteration of wheat flour is not practiced to any extent in this country. The most common adulteration arises from grinding with wheat foreign seeds and other foreign matter, rust, smut, etc., which may be present in the grain. Other adulterations are the mixture with wheat flour of the starch or flour of maize and other cereals. The adulteration with any form of terra alba or white powdered earthy substance is exceedingly rare. Although some attempts have been made to introduce such adulterations in this country they have not reached any commercial success. The adulterations, with the exception of those with white earthy powders, are most readily ascertained by microscopic examination for foreign matters and other varieties of starch than grow naturally in the wheat.

=Standard.=--The United States standard for flour is as follows:

=Flour= is the fine, sound product made by bolting wheat meal and contains not more than thirteen and one-half (13.5) percent of moisture, not less than one and twenty-five hundredths (1.25) percent of nitrogen, not more than one (1.0) percent of ash, and not more than fifty hundredths (0.50) percent of fiber.

=Graham flour= is unbolted wheat meal.

=Whole wheat flour=, entire =wheat= flour, improperly so called, is fine wheat meal from which a part of the bran has been removed.

=Gluten flour= is the product made from flour by the removal of starch, and contains not less than five and six-tenths (5.6) percent of nitrogen and not more than ten (10) percent of moisture.

=Age of Flour.=--The freshly ground flour is most highly esteemed by many consumers on account of palatability and freedom from all danger of mold and ferments. Older flours are likely to lose flavor, become moldy and infested with weavil and other insect pests. The last-named evils are avoided by the use of wheat containing no fungus, none of the eggs of the weavil, nor of other insects, and enclosing the freshly ground flour in packages not accessible to infection. Even then it is advisable to consume the flour as soon as convenient after the milling process. Many manufacturers and experts contend that flour is improved by keeping for a certain length of time, and this contention is based on the assumption that the flour assumes a lighter color and improves in flavor on keeping. There is of course a certain limit to improvements of this kind.

=Substitutes for Flour.=--Wholesome ingredients are used in part instead of flour in bread making, and when that fact is clearly made known the admixture of these substances with flour is not considered an adulteration. Bread which is made of an admixture of Indian corn meal with flour or rye flour with flour or other cereal products is well liked by many people. Potatoes are also used

very often in bread making. Acorns, buckwheat, and other farinacious and oily substances are also employed. The admixture of inert substances with flour merely to increase the bulk and weight of the loaf, even if notified, cannot be regarded as other than an adulteration.

In times of famine such admixtures are sometimes made in order to increase the size and weight of the loaf. Such substances are known in times of famine as “hunger bread.” Finely ground straw, bark, the hulls of nuts, etc., are often used for this purpose. These bodies practically have no nutritive value and serve no useful purpose except to deceive the eater respecting the quantity of bread he consumes.

BREAD.

The term “Bread” when used alone is understood in this country to apply to bread made from wheat flour or some form of wheat. If made from other cereals a prefix is used to distinguish this fact, as Indian corn bread, rye bread, etc. The term bread includes also the materials which are used necessarily therewith in the ordinary process of baking. Thus, the term bread would apply to a loaf which contains not only the wheat flour as the base and chief part of its mass but also the yeast or other leavening agent employed, together with salt, lard, or butter used in its preparation. The presence of these bodies, used in the sense above described, is not regarded as an adulteration. The term “bread,” however, is not to be used to include those other forms of nutriment made from wheat flour in which condimental substances, especially sugar, are used to such an extent as to give the dominant taste of the condiment or condiments employed. Thus, the ordinary cake of all descriptions, tarts, puddings, and other edible substances made largely from wheat flour, but to which the condiment or condiments impart a distinct taste, are not included under the term bread.

In the generic sense the term bread may be used in the largest signification to signify food in general.

=Varieties of Bread.=--In general all forms of bread may be divided into two great classes, leavened and unleavened. By far, the greater quantity of bread consumed belongs to the former class. Unleavened bread is used chiefly for certain religious festivals, in the form of biscuits or in certain varieties of Indian corn bread such as hoe cake, johnnie cake, etc. Of the leavened bread there are two distinct classes, namely, bread which is baked and eaten cold and bread which is consumed hot from the oven. Bread intended to be consumed cold is generally eaten within twenty-four or forty-eight hours from the time of making though some varieties may be kept for an indefinite period. The use of hot bread is not commended by hygienists though it is difficult to see why, when properly made, the consumption of a good hot roll can be regarded as injurious. The apparent injury which may result therefrom is probably due to the larger quantity eaten on account of greater palatability than is the case with cold bread. That variety of bread which is baked so as to present a maximum of crust and made of flour which gives a tough consistency to the loaf is most highly regarded both for palatability and nutritive purposes. This form of bread is improperly called French or Vienna rolls in this country.

Unleavened bread is particularly advisable for use in emergency rations for marching soldiers, in logging camps, etc. This bread is compact, comparatively free of moisture and has a high nutritive value. The leavened bread may be divided into distinct classes in respect of the leavening agent employed.

Class 1 is bread in which the leavening agent is yeast. Class 2 is bread in which the natural ferments residing in the flour or wheat are utilized for the leavening agent as in the making of that variety known as salt rising bread. Class 3 includes that form of bread in which the leavening is secured by chemical reagents mixed with the dough. Class 4 includes that variety in which a leavening reagent such as carbon dioxid or air is mechanically incorporated with the dough during the kneading process.

Unleavened bread is also divided into several technical forms. The first class includes the biscuit of commerce, sometimes incorrectly called crackers, and intended to be used soon after preparation. The second class includes biscuits which are intended for long storage and transportation. The third class includes wafers and other delicate forms of unleavened bread for special use. Class 4 is the unleavened loaves which are made most frequently from Indian corn meal and intended to be eaten while still hot. Class 5 includes any miscellaneous unleavened loaves or cakes made in various ways and for different purposes.

In nearly all forms of unleavened bread made from wheat flour the dough is thoroughly beaten, and mechanically mixed or kneaded, in order to make it lighter in color and more crisp and hard after baking.

=Yeast.=--Bakers’ yeast is one form of the ordinary yeast ferments or a mixture thereof producing alcoholic fermentation under proper conditions. All flour contains a certain quantity of sugar which is easily fermented. By the action of the yeast upon this sugar carbon dioxid and alcohol are formed. The particles of carbon dioxid become entangled in the gluten of the wheat flour when it is

mixed into a dough and thus make the mass spongy and light. When placed in the oven to be baked these minute particles of carbon dioxid expand still more and produce additional lightness and sponginess of the loaf. The yeast may be propagated from one mass of dough to another, may be used in a moist state or, as is very commonly the case, manufactured in large quantities, and sold either moist or more commonly in a partially dried and pressed cake.

=Spontaneous Ferments.=--All cereals contain ferments of a character to produce alcoholic fermentation spontaneously under proper conditions. It is possible even to ferment dough by seed from one loaf to another or by developing a spontaneous fermentation. This method is quite a common one in the rural districts, and all bread made in this way is known as salt rising bread. It may be made according to the following receipt:

A quarter of a pint of fresh whole milk is slowly heated to near the boiling point, but not allowed to boil. This process will sterilize the milk and prevent the development of a too rapid lactic fermentation in the subsequent processes. The heated milk is added to a quantity of maize meal sufficient to make with the milk a stiff batter, and the whole is thoroughly mixed. The vessel containing the batter is wrapped with paper and then with a heavy flannel cloth, and kept in a warm place at a uniform temperature of about blood heat for several hours, until fermentation is fully established and the batter assumes a definite sour odor. At this point a teaspoonful of salt is stirred into a pint of blood-warm water and into this a sufficient quantity of high-grade wheat flour is stirred to make a moderately stiff batter. This is thoroughly mixed with the sour mass obtained by the previous fermentation and the mixture exposed for from three-fourths to one hour to a blood heat as before. If the fermentation has been well conducted the mass will now be in a sufficiently active state to secure a proper porosity of the loaf. The salt rising thus prepared is mixed with a wheat flour dough made with warm water in sufficient quantities to make from four to six loaves, the whole mass well kneaded, molded into loaves and put aside at a temperature of blood heat until the fermentation has proceeded far enough to make the loaf light and spongy. The loaf is then baked in the ordinary way.

=Chemical Aerating Agents.=--In this country a very common method of aerating bread is practiced, based upon the use of certain chemical reagents which when mixed in the dough set free carbon dioxid. These reagents are known as baking or yeast powders and are especially prized by reason of the fact that it is possible with their aid to prepare in a few moments a light spongy loaf or roll which would require from 10 to 24 hours to make by the ordinary fermenting with yeast. The principal objection to the use of baking powder lies in the fact that the residues arising from the chemical reaction are necessarily left in the loaf. While these residues may not have any specific or poisonous properties they increase the quantity of mineral matter in the bread, and this mineral matter is in the inorganic state and as such does not take any part in the process of nutrition. It can only be regarded as a waste product, burdening, to that extent, the excretory organs of the body.

=Constituents of Baking Powder.=--The essential constituents of baking powder are a carbonate of some kind and an acid reagent capable of decomposing this carbonate and setting the carbon dioxid free. The common carbonate of a baking powder is bicarbonate of soda. The classification of baking powders rests upon the acid elements which they contain. They may be classified as follows: (1) Cream of tartar baking powder, in which the acid constituent is cream of tartar which is known chemically as acid potassium tartrate. Other forms of tartaric acid may be used in baking powders of this class but they are not common. (2) Phosphate powders, in which the acid constituent is phosphoric acid usually in the form of the acid phosphate of lime. (3) Alum powders in which the acid constituent is alum or some form of aluminium sulfate, usually the basic sulfate of alumina.

The acid and basic constituents of these powders may be kept in separate containers and mixed together at the time of making the dough. A more common form is to use them in such a way that until they mix with the dough they do not exert any notable effect upon each other. For instance, perfectly dry bicarbonate of soda and perfectly dry acid potassium tartrate may be mixed together and kept for quite a while without any notable decomposition of the bicarbonate taking place.

In order to render any such possible action minimum in its effect it is customary to add to the mixture a small quantity of starch, milk sugar, or some other diluent. These materials tend to keep apart the particles of acid and base and render it possible to make a mixture of them which may be kept for a long while without any notable loss of leavening power. When a cream of tartar baking powder is mixed with dough the moisture of the dough gradually dissolves the two ingredients and in this state a chemical reaction occurs between them. The carbon dioxid is set free as a gas, commonly known as carbonic acid. The mineral substance which results is a tartrate of sodium and potassium that is a union of tartaric acid with potash and soda. This compound is commonly known under the term of Rochelle salts. If there be a sufficient quantity of water in the bread to allow the Rochelle salts to crystallize in the usual way a portion of the water becomes incorporated with the salt. Two teaspoonsful of a tartrate baking powder leave a

residue of about 11 grams (165 grains) of crystallized Rochelle salts in the loaf.

=Phosphate Powders.=--As has already been said, the acid constituent of phosphate powder is chiefly acid phosphate of lime. In this case the acid phosphate of lime decomposes the bicarbonate of soda with the production of carbon dioxid and leaves a residue consisting of a mixture of sodium and lime phosphate. If in two teaspoonsful of phosphate powder there are approximately 16 grams (250 grains) there is formed a crystallized residue, about an equal weight of phosphate of soda and lime, which is left in the loaf.

=Alum Powders.=--Perhaps by far the largest part of baking powders used contain alum in some form as the acid constituent. Formerly the common substance known as alum or burnt alum was employed but in late years an aluminium basic salt known as basic sulfate of aluminium has largely succeeded the old form of alum. When the reaction takes place in the dough between these two constituents of alum baking powder there is formed an equivalent quantity of sulfate of soda and hydroxid of alumina if the acid constituent be basic aluminium sulfate.

The quantity of residue left in the loaf if two teaspoonsful of baking powder be used is about 11 grams (165 grains).

=Harmfulness of Baking Powder Residues.=--The question of the harmfulness of the residues left by the various forms of baking powder is one which has been of much interest to the hygienist and physician. It is not claimed in any case that these residues are beneficial. The principal question which has been discussed is which of them is the least harmful. This is a question which it is not proper to enter into in this manual. It might, however, not be out of place to say that the use of chemical reagents for leavening bread is not as advisable as the use of the ordinary fermentation. It would be better, evidently, if all people used more yeast bread and less baking powder rolls. At the same time the utility and convenience of baking powder cannot be denied, and this is a factor which must be taken into consideration in the general discussion and final resolution of the question.

=Character of Alum Residues.=--Every one is agreed that the substance known as alum, namely, the sulfate of alumina in conjunction with another mineral or base, such as soda, potash, or ammonia, is not a desirable constituent of food products. In the manufacture of baking powders containing alum an effort is made to so balance the constituents that when the reaction is completed no undecomposed alum remains. If this condition is secured in every instance the materials which remain in the bread are not alum but the residues above mentioned, consisting of aluminium hydrate, and sulfates of soda, potash, or ammonia.

The residue of chief importance is the hydroxid or hydrate of alumina, which is the form in which the alumina itself should appear when a complete reaction like that defined above takes place. When the hydroxid of alumina is dried and especially when ignited it is converted into an oxid of alumina which is highly insoluble in water and only slightly soluble in a very dilute acid solution. The claim is made by the manufacturer of alum powders that the aluminium residue which is formed is insoluble in the digestive juices and therefore cannot produce any effect usually ascribed to the soluble salts of aluminium. It is important that the conditions which are found in the baking of a loaf are such as to produce this highly desirable result. The temperature of the interior of the loaf during baking does not rise much above that of boiling water, although the exterior temperature, which is sufficient to produce the browning of the crust, is very much above that temperature. It is evident that as long as any considerable proportion of water remains in the loaf it will be difficult to raise the interior of the loaf to the temperature just mentioned, and if this were done the caramelization would take place throughout the whole loaf. Unfortunately, from a scientific point of view the investigation of this subject has not been always undertaken under conditions which are wholly beyond criticism. Many of the investigations have been in the interest of rival baking powder companies, and it is very desirable that this matter should be undertaken in a wholly unbiased way and conducted in such a manner as to lead to results which all will accept. Chemical and physiological investigations, which have even as a remote object the promotion of the sale of one compound and the repression of the sale of another, lose at the outset much of that claim upon the public confidence which such investigations made from a purely scientific point of view should have.

General Statement.--In respect of the use of chemical leavening agents in general it may be said that they introduce an extraneous product into the bread which is not likely to promote the health and which, therefore, on general principles should be excluded. On the other hand, large experience has shown that the consumption of bread made by these leavening agents does not produce any general effect upon the public health which is noticeable. This, it is understood, is not any valid argument in favor of the process. It must also be acknowledged that a fermentation of a bread with yeast also introduces extraneous matter into the food, viz., alcohol and congeneric products of fermentation, and hence this process may be open to a certain extent to the same

objection as the one above. It is too early yet to formulate definite principles either of inclusion or exclusion of these products, and the purpose of this manual is secured when the general character and effects thereof are briefly outlined.

=Composition of Bread.=--Because of the many different methods of bread making which are practised it is not possible to give in a chemical form an analysis which would do more than represent in general the character of the bread in common use. For instance, the quantity of water which is found in bread varies greatly and the nature of bread itself must be influenced by the character of the flour from which it is made. The flour depends upon the quality of the wheat used in its manufacture. Hence the same brand of bread prepared in the same way and baked in the same manner must necessarily vary in composition from season to season and even from day to day. It must be understood also that it is a very common custom in the United States to use milk in the mixing of dough, and thus a food product is introduced which of itself is not of constant character. Some bakers use whole milk, others skimmed, and others sour milk.

A very good formula for mixing dough for bread making consists in using the following proportions of ingredients mentioned:

Flour, 2,000 grams Whole milk, 500 „ Water, 650 „ Salt, 25 „ Yeast cake, 10 „

When properly leavened and kneaded and baked these quantities of materials will make a loaf of bread weighing 2750 grams.

Average Composition of Bread.--In the following tables are given the average composition of bread of different classes. Class 1 is composed of loaves of the so-called Vienna or French type; Class 2 consists of what is known as home made bread or bread baked at the home and not in the bakery; Class 3 consists of bread made from graham flour; Class 4 consists of bread made largely of rye flour; Class 5 is a second collection of home made bread which may be very properly compared with Class 2; Class 6 consists of bread of miscellaneous origin bought on the open market. The data given represent the mean composition of numbers of samples (Bull. 13, Bureau of Chemistry):

A Typical American High-grade Yeast Bread.--In conjunction with the actual analyses given above it is of interest to combine as many analytical data as can be conveniently secured for the purpose of determining what the average composition of a high-grade typical yeast bread is. This comparison leads to the following composition:

Moisture, 35.00 percent Protein, 8.00 „ Ether extract, .75 „ Starch and sugar, 54.45 „ Fiber, .30 „ Ash, 1.50 „

Of the ash mentioned in the above analysis .50 percent may be ascribed to the natural mineral ingredient of flour and 1 percent to added salt.

The chief variations from the typical composition of bread made from high-grade flour are found in the moisture and ether extract. The moisture may rise above 40 percent in breads made of flour rich in gluten or sink to 30 percent or under when flour of an inferior gluten content is employed. The quantity of ether extract depends chiefly upon the amount of milk which is used in the making of bread and the amount of fat employed either in the bread itself or in greasing the pan in which it is baked. There is great difficulty in extracting a fatty body which has been mixed with a glutinous material like flour. The analytical data, therefore, do not represent in the ether extract all the fat naturally present in the flour plus that added in the making of dough or in baking.

The quantity of moisture in bread may also be determined largely by the time of baking and the temperature of the oven. A bread baked for a long while at a low temperature will be much drier than a bread baked quickly at a high temperature. The high temperature solidifies the exterior of the loaf so as to make it difficult for the interior moisture to escape. By quickly baking the bread the temperature of the interior does not reach so high a temperature as in an oven with a low temperature and a long-continued heat.

Standard for Moisture.--The quantity of moisture in bread of standard quality in the District of Columbia may not exceed 31 percent.

The average temperature of the baking oven is about 240° C. (464° F.).

=Quantity of Sugar in Bread.=--The quantity of sugar found in fermented bread is always less than that present in the flour, added in milk, or otherwise introduced in the preparation of the dough. The sugar disappears largely under the influence of the fermentation due to the yeast.

=Quantity of Ash.=--The quantity of ash in bread is uniformly higher than the content of mineral matter in the flour. This is due to the addition of common salt which is uniformly employed in all bread, and in the case of bread made from baking powder the retention of the mineral residues in the loaf increases to that extent the content of ash. With the exception of the ash, the ether extract or fat, the sugar, and the dry material of bread correspond in quantity to the same materials in the flour from which it is made, except the loss due to the caramelization of the crust.

Acidity of Bread.--The development of the lactic acid ferments is important in regard to hygienic conditions and to palatability. Flour contains practically no acid in a free state, and the acidity of bread is itself due to the changes which take place in its preparation under the influence of the ferments therein. Bread baked in the usual manner after the yeast ferments have exerted their activity shows the presence of acetic acid, lactic acid, and other acids and salts. The acidity of bread adds to its palatability and also, doubtless, to its digestibility. Bread, containing, as it does, a large percentage of protein, is digested in an acid medium. The natural acidity of bread, therefore, must be regarded as beneficial.

=Comparative Nutritive Properties of Indian Corn Bread and Wheat Bread.=--There is a widespread opinion that the products of Indian corn are less digestible and less nutritious than those of wheat. This opinion amounts to a conviction in most European countries, where the products obtained by the milling of Indian corn are not regarded as fit for human food in an unmixed state. The above opinion, it appears, has no justification either from the chemical composition of the two bodies or from recorded digestive and nutritive experiments.

A study of the analytical data of the whole grain shows that in so far as actual nutrition is concerned the maize is fully as nutritious as wheat. In respect of its content of fat Indian corn and its direct products easily take precedence of all the other cereals, with the exception of hulled oats. In round numbers Indian corn flour or bread made therefrom contains twice as much fat or oil as wheat, three times as much as rye, twice as much as barley, and nearly as much as hulled oats. In regard to digestible carbohydrates, that is digestible starch, sugar, dextrin, and fiber, Indian corn flour possesses a higher content than hulled oats and almost the same content as wheat. In regard to digestible protein Indian corn has nearly the same quantity as the other leading cereals, except oats. What it lacks, however, in its quantity of protein in so far as nutrition is concerned is more than made up in its excess of fat.

=Comparative Digestibility and Nutrition of Wheat and Indian Corn from Experiments Made in South Dakota Station, Bulletin 38.=--Pigs were fed with Indian corn and wheat, or rather the ground Indian corn and ground wheat, and it was found that pound for pound there was a greater gain in the case of Indian corn flour than wheat. For 100 pounds of flour fed the average gain with Indian corn was 21.83 pounds and where wheat flour was used 20.79 pounds. These experimental data show that in regard to nutritive properties Indian corn flour cannot be considered inferior to wheat flour. Indian corn bread is particularly well suited for persons

engaged in hard manual labor. A ration which is composed largely of Indian corn products and oatmeal is found to be particularly valuable for those engaged in lumbering, harvesting sugar-cane, etc.

Indian Corn Flour Pudding.--Various forms of pudding are prepared from Indian corn flour. Among the most important is that known in the New England States as hasty pudding and in the west and south as mush. A simple method of preparing Indian corn pudding, hasty pudding, or mush is to stir into water, very slowly, the Indian corn flour in such a way as to avoid the formation of lumps. The flour should be sifted into the water either cold or at boiling temperature and the mixture vigorously stirred meanwhile. By this means a thin, uniform paste is secured which is allowed to cook slowly until quite thick in consistence and until all the starch granules are thoroughly disintegrated. The product is improved by allowing to stand for several hours at near the boiling point after the cooking is finished, provided precautions are taken not to allow the mass to become too solid. This product is eaten hot with butter, milk, or cream, or is much prized when allowed to cool, cut into thin slices and fried. A very important dish for the children of working people and farmers of the south and west is mush and milk, namely the product above mentioned eaten with skim milk. This mixture forms a palatable and wholesome diet. Various other forms of pudding are made into which Indian corn enters to a greater or less degree.

=Composition of Biscuits.=--The composition of a biscuit or dry unleavened bread does not differ essentially from that of the ordinary bread except in the content of moisture. The biscuits are usually baked in thin cakes or loaves which become heated throughout and sometimes caramelize throughout a large part of their substance. This favors the expulsion of the greater part of the moisture which the dough originally contained. The average composition of biscuits is shown in the following data:

Moisture, 7.13 percent Protein, 9.43 „ Ether extract, 8.67 „ Fiber, .47 „ Ash, 1.57 „ Salt, .99 „ Starch and sugar, 73.77 „

In the dry substance:

Protein, 10.18 percent Ether extract, 9.33 „ Fiber, .53 „ Ash, 1.70 „ Salt, 1.08 „ Starch and sugar, 78.79 „ Calories, 4,755

The above data show that biscuits vary in composition from bread chiefly in their content of moisture and fat or oil. The moisture, as is noted, is very low, while the quantity of fat which the biscuit contains is from 8 to 10 times as great as that contained in flour from which they are made. The salt content and the mineral ingredients of the biscuit are often higher than in bread or flour. Inasmuch as a large quantity of fat and salt are used commonly in the manufacture of biscuits the presence of these bodies cannot in any sense be regarded as an adulteration. In forty-eight samples examined only four were free of notable quantities of added fat. In one case over 16 percent of fat was found, and as it has been shown that all the fat which is added is not extracted by ether it is evident that in this case an amount of fat equal to 20 percent of the weight of the flour may have been used.

It appears, from a study of the composition of biscuits, that it is advisable to use them as a relish or delicacy for eating with cheese, etc., in ordinary daily life, while they become almost a necessity in some form or other in the preparation of emergency rations for marching armies, on shipboard, in logging camps, etc. It is not advisable to employ them in the daily diet to the exclusion of bread. Their nutrient contents have, in comparison with bread, a lower coefficient of digestibility, due largely to the added fat.

=Amount of Sugar Lost in Fermentation.=--The total quantity of sugar and other carbohydrates lost in fermentation amounts to about 2 percent of the weight of flour used. Sometimes it is much greater and sometimes less than this. The nutritive value of the product is diminished in proportion to the extent of the loss of sugar. The carbon dioxid produced during fermentation has no food value, and the alcohol is largely lost in the form of vapor during the process of baking. About half the loss is due to carbon dioxid and half to alcohol. The alcohol, although lost mostly during the baking, serves a useful purpose,--in the expansion of the vapor it aids the carbon dioxid in making the bread more porous. The hydrolysis which takes place in baking converts some of the starch to dextrinoid or saccharoid conditions. It is evident that from 6 to 8 percent of total starch present in the flour is changed during the fermentation and baking into more or less soluble forms.

[Illustration: FIG. 36.--COMPARATIVE APPEARANCE OF BREADS OF DIFFERENT KINDS.]

=Texture and Size of Loaves Made from Different Kinds Of Flour.=--The variations in bread and size of loaves made from different kinds of flour when the conditions of fermentation and baking are the same depends upon the texture and quantity of the gluten material in the flour. The difference in the appearance and size of loaves is shown by a photograph of the cross-sections of three loaves of bread in Fig. 36.

It is seen that the loaves made from graham flour and entire wheat flour are somewhat coarser in structure and are less in size than those made from the same quantity of standard patent flour.

MACARONI.

The preparation of wheat flour of a high glutenous character and molded into various forms, usually tubes, cylindroids, or fine shreds, is known in the trade under various names such as noodles, spaghetti, and macaroni. An examination of a number of these bodies shows them to have the following average composition:

Moisture, 9.66 percent Protein, 12.02 „ Ether extract, .42 „ Crude fiber, .56 „ Ash, .78 „ Starch and sugar, 77.12 „

In the dry substance:

Protein, 13.33 percent Ether extract, .47 „ Crude fiber, .62 „ Ash, .86 „ Starch and sugar, 85.34 „ Calories, 4,428

These bodies, it is seen, do not have a composition very different from that of a first-class bread except in their content of moisture and protein. They are made from various kinds of wheat, especially hard wheat which forms a tenacious gluten product well suited to molding into the different forms which these bodies have. Their nutritive value is practically the same as that of good wheat bread of the same moisture content.

=Domestic Macaroni.=--The introduction of varieties of wheat with the properties suitable for making macaroni has been thoroughly exploited by the Department of Agriculture. The macaroni wheat grown as a subvariety is known botanically as _Triticum durum_. The durum wheats are not regarded as of equal value to the ordinary wheats for general milling purposes and command a lower price. The French name is Blé dur and the German name is Hartweizen. The wheat of this subspecies grows rather tall, having broad, smooth leaves of a whitish green color and a very hard cuticle. The heads are comparatively slight in most varieties, compactly formed, and occasionally very short. All the durum wheat is bearded and the beards are exceptionally long. The kernels are hard and glassy, often partly translucent. They are generally yellowish white in color, occasionally inclined to red, and the grains are generally rather large. In other aspects this wheat resembles barley and for this reason in Germany it is often called Gerstenweizen. The general appearance of these wheats both in the field and in the individual heads is shown in the accompanying figures.

[Illustration: FIG. 37.--A FIELD OF DURUM WHEAT.--(_Courtesy of Bureau of Plant Industry._)]

[Illustration: FIG. 38.--DROUGHT-RESISTANT MACARONI WHEATS (HEADS AND GRAINS).

1, Kubanka; 2, Nicaragua; 3, Velvet Don; 4, Black Don; 5, Wild Goose.--(_Bulletin No. 3, Bureau of Plant Industry, U. S. Dept. of Agriculture._)]

Macaroni wheats are well adapted to semi-arid regions; in fact it may be said that they are the product of such an environment rather than adapted to it. For this reason they are wheats which are able to resist continued dry weather and high temperature. These wheats do not grow well in acid soils but flourish best in an alkaline soil of fine texture and well supplied with humus and the necessary plant foods. The largest quantity of macaroni wheat is grown in east and south Russia. These wheats have given very good results in the semi-arid regions of the United States. The appearance of the wheat as it grows in the field is shown in the accompanying plate.

The domestic macaroni is now made in many factories in the United States and there is a continually increasing demand for the domestic article. The hardiest varieties of wheat are used in the manufacture of this article in the United States, especially the hard Kansas winter wheat.

Composition of Domestic Macaroni.--In the table below is given the mean composition of twenty samples of macaroni of domestic origin, made from domestic wheat. In the second column is given the mean composition of five samples of imported macaroni.

DOMESTIC FOREIGN PRODUCT. PRODUCT. Moisture, 10.27 10.32 Fat or ether extract, .40 .35 Crude fiber, .49 .53 Protein, 11.61 12.27 Starch and sugar, 76.52 76.10

Preparation of Flour for Macaroni.--The term Semolina or Semola (Italian) or Semoule (French) is usually applied to the flour used in the manufacture of macaroni. In the United States the flour which is used is obtained by selecting the hardest wheat and preparing the flour in the usual manner. In France and Italy the preparation of semolina is accomplished in separate mills. The devices for grinding are essentially the same as those for producing the best grade flour, the main difference being that the wheat is moistened slightly before grinding and the flour is less fine than ordinary baking flour.

Evidently very slight changes in the method of milling would enable the ordinary mill to produce a fine grade of macaroni flour either from the macaroni wheat or from any very hard glutinous wheat grown in the United States.

=Manufacture of Macaroni.=--As practiced in the best districts of Italy, macaroni is manufactured according to the following method:[27]

[27] Fairchild, U. S. Dept. Agr., Bureau of Plant Industry, Bulletin 25.

The durum wheat is ground into semola and sieved to remove the starchy part of the grains and leave the clear, light amber, or glutinous part. Three or four grades of quality are made, and these depend on the size of the sieve meshes.

The semola is put into a special iron mixer, shaped like an old-fashioned artillery mortar, except that it is square instead of cylindrical, and furnished in the bottom with special screw-shaped fans with which to stir the paste or dough. Boiling water is added to the semola and the dough is mixed for about seven minutes. The mass is then put on a flat, circular kneading board and kneaded by two sharp-edged parallel beams which rise and fall as the table turns and press into the dough as they descend. A few minutes of kneading are sufficient and the homogeneous dough is then put into the cylinder and the piston descends upon the mass, forcing it in strings slowly through the perforated plate at the bottom. Fifteen minutes are required to convert the gallons of dough into thousands of feet of yellow macaroni. The yellow color is produced by the use of saffron or of a coal tar dye of which a very small quantity is put into each batch of dough. This is a reprehensible practice.

As soon as the strings of fresh paste which issue continually from the die are of the proper length they are cut and thrown over a reed pole and carried into the sunlight, if the weather is fair, or into sheltered terraces, protected by curtains from the rain, if the weather is unfavorable. On bright days the strings of macaroni are exposed to the sunlight only two hours. They must be dried out only slightly before being cellared for the night in dungeon-like underground vaults similar to the Bavarian beer cellars.

For twelve hours or more the poles of macaroni are kept in these damp places, until the dough has become moist and pliable again and the strings have lost the brittleness that the exposure to the sunlight has given them. From the cellars the poles are carried to shaded storehouses open on all sides to the air but not lighted from above. Here, in great masses of millions of strings, they hang for several days, from eight to twenty being required, depending upon the dryness of the atmosphere. According to the statements of a manager of a factory this process of drying is necessary to give to the brittle paste a horn-like toughness and fit it to withstand the rough handling to which it will be subjected without breaking into small pieces.

In all this simple process the one point at which bacteria might have a chance to play a rôle is in the first drying, cellaring, and subsequent slow drying in the shade. The theory that the water is responsible for the flavor must rest, it seems to the writer, on other than bacterial grounds, for from the appearance of the tank which supplied the hot water the inference is easy that the water is chalybeate, for the tank was incrusted with iron.

ROLLS.

The term rolls is given to bread usually leavened with yeast or baking powder, and usually eaten warm, or hot. The term biscuit is generally but improperly used in this country for hot bread made with baking powder. The composition of rolls varies greatly with their method of preparation. Those made with yeast have practically the same composition as ordinary fermented bread, while those made with a baking powder or with exceptionally large additions of milk, butter, or lard vary in composition accordingly. In the making of hot rolls with baking powder, lard or butter is commonly used to a very large extent as “shortening.” These fatty bodies render the gluten less tenacious, and the roll is thus easily broken and is without toughness or elasticity. Owing to this irregular use of shortening and of mineral matter, including salt, the composition of rolls of commerce is extremely variable. In eleven samples of rolls analyzed, for instance, the content of moisture varied from 7 to 34. Evidently the sample sold as a roll which contained only 7 percent of moisture was in point of fact a biscuit and not a roll. The percentage of ether extract in these samples varied from .43 to 7.55. The average composition of the eleven samples is as follows:

Moisture, 27.98 percent Protein, 7.48 „ Ether extract, 3.41 „ Crude fiber, .60 „ Ash, 1.31 „ Salt, .69 „ Starch and sugar, 59.82 „

In the dry substance:

Protein, 10.46 percent Ether extract, 4.74 „ Crude fiber, .77 „ Ash, 1.81 „ Salt, .81 „ Starch and sugar, 82.99 „ Calories, 4,538

CAKES.

Wheat flour is one of the principal constituents of that class of sweetened bread known generally as cake. The kind and character of cake vary so greatly that no general statement of any very great value can be made respecting the average composition. In addition to the sugar and flour which are used in the manufacture of cake various flavoring ingredients or essences are employed, and usually excessive quantities of butter or lard for shortening purposes. In addition to this, other forms of cake are cooked in oil after the dough is made, thus adding an additional quantity of fatty matter to the material. Eggs are also a common constituent of cakes and these introduce into their composition additional quantities of protein and fat. Baking powder is very generally used in this country instead of yeast for the leavening of the cake and thus an additional quantity of mineral matter is introduced into their composition.

In the manufacture of sweetened cakes the flour is mixed with eggs and sugar and butter or lard to the proper consistency with or without the use of milk or cream. The cakes are baked in all kinds of sizes and shapes and may be eaten plain or in layers separated by a jelly, marmalade, or some other preserve. The exterior of the cake is often frosted with a mixture consisting of the white of egg beaten up with white sugar. The methods of mixing the ingredients of these cakes as well as the method of frosting are so various that it would not be possible to undertake any minute description of them.

For flavoring various materials are employed, either the real article or the imitation thereof, such as artificial strawberry, vanilla, etc. The cake or sweet cake is a very common dainty which is served at dessert. The ordinary cane sugar of commerce is the common sweetening matter usually employed in the refined state although sometimes yellow sugar is used. Honey is not so commonly used as a sweetening agent in this country as it is in European countries.

In the manufacture of one of the common varieties known as ginger cake sugar-cane sirup or molasses is a common ingredient.

An examination of a large number of samples of cake shows the following average composition:

Moisture, 11.65 percent Protein, 6.29 „ Ether extract, 9.81 „ Crude fiber, 0.50 „ Ash, 1.17 „ Salt, 0.39 „ Sugar, 24.57 „ Starch, 46.01 „

In the dry substance:

Protein, 7.29 percent Ether extract, 11.41 „ Crude fiber, 0.57 „ Ash, 1.30 „ Salt, 0.44 „ Sugar, 27.84 „ Starch, 51.59 „ Calories, 4,805

A study of the individual data shows extremely wide variations from the mean. The ether extract in the moisture samples in some cases amounted to over 19 percent and in the dry substance to over 24 percent. The moisture in one case was over 64 percent while in the dry cake of biscuit character it sinks below 5 percent and in one case below 4 percent. The average data, therefore, are to be considered only as a representative of this class of bodies and not as a type of any particular variety.

=Adulterations.=--It is difficult to speak of adulterations of a substance of the composition of cake. Any wholesome flavoring or sweetening ingredient or other wholesome ingredient may be used in the manufacture of a cake of this kind without being an adulterant. From this class of bodies, however, there is excluded artificial colors and artificial flavoring essences bearing the name of genuine. A yellow cake which does not owe its color to the eggs or other normal ingredients employed must be regarded as an adulterated article, especially if the dye used in producing the yellow is one of the coal dyes or coal tar derivatives such as naphthol yellow. The use of imitation fruit flavors such as the so-called strawberry, blackberry, raspberry, vanilla, etc., is also to be regarded as an adulteration. The adulteration of cakes may be regarded as confined particularly to these two classes of article assuming that all the other ingredients are wholesome and without injurious effects upon the digestion. The eggs used in cake making should be fresh and palatable. Too often passé storage eggs and eggs broken and preserved with borax or formaldehyde and unfit for consumption have been used by the bakers of cakes.

Mineral coloring matters have sometimes been found in cakes and these are more objectionable by far than the artificial colors above mentioned. Where molasses from sugar-cane factories is used in the manufacture of cake a considerable trace of chlorid of tin or of zinc salts may be found therein, derived from the wash used in the centrifugal when drying sugar crystals or from the

process of bleaching the molasses. This must be regarded as a very serious adulteration and molasses of this kind should never be used in the manufacture of cake nor for edible purposes upon the table. Sulfurous acid may also be absorbed during the process of bleaching the sugar-cane juices.

It is needless to add that cake with its complex character should be eaten as a relish rather than a diet. There is no hygienic or dietetic objection to the mixture of sugar with the flour in the making of ordinary sweetened bread. Such bread must be regarded as highly nutritious and as differing from ordinary bread only in a disturbance of the natural food content of the loaf caused by the addition of a carbohydrate to the bread. Many of the cakes which are sold contain so small a quantity of sugar that they ought not to be classed with the sweet cake. Out of the whole number of samples used in the making up of the above average only four contained so little sugar as to be ineligible to bear the name of sweet cake or sweetened bread.

=Breakfast Foods.=--A very large variety of cereal preparations are on the market under the general name of breakfast foods. These preparations are made directly from the cereals more or less completely ground by subjecting them to certain manipulations of a fermentative or culinary character by means of which the preparations are made ready for immediate consumption or at least with only a moderate degree of additional cooking. The changes which take place in the preparation of cereals for breakfast foods are of two general characters, namely, those produced by fermentative action with malt, yeast, or other ferments, and, second, changes produced by heating, either in the moist or dry state. Often both sets of changes are produced in the same product. The general difference, therefore, between a so-called breakfast food and the raw material from which it is made is found in the conversion of more or less starch into sugar and the change in the composition of the material produced by moist heat or dry heat. In the latter case the temperature may be raised to the state of considerable caramelization.

Breakfast foods may also contain added condimental substances, such as salt, sugar, etc., sometimes used in their preparation. Nearly all the cereals or mixtures of cereals are represented in these prepared foods. Oats probably occupy the first rank and the preparations of oatmeal have to a large extent in the United States taken the place of home-prepared oatmeal for the breakfast table. Wheat, barley, and Indian corn are not far behind oats in their contributions to the numerous varieties of breakfast foods.

The particular methods of preparation are usually trade secrets and at any rate the description of the extensive technical processes would be improper in this manual. The secrets, however, are merely methods of manipulation, since it is certain that the changes of a chemical nature which take place are of the general character or class described above.

Breakfast foods are usually sold under trade-mark names which may or may not give an indication of their origin or character. Sometimes, in fact, the trade name gives a false indication and the use of such trade names must be considered as entirely reprehensible. Whenever a name used is descriptive it should be used in a practical sense and not for the purpose of misleading or deceiving. Breakfast foods may represent practically the whole grain or the grain with a removal of a proportion of the outer covering or they may represent the refined flour from which all or a considerable proportion of the germ and some of the rich nitrogenous ingredients have been removed.

The attempt to give a list of the names which have been applied to breakfast foods would consume many pages and be of little value.

=Composition of Breakfast Foods.=--In so far as possible the breakfast foods noted in the following tables have been arranged in accordance with the raw material from which they have been produced and the data given represent the average composition of breakfast foods of the classes mentioned. Individual variations from the average are often very great.

Class I.--Breakfast foods made from Indian corn products. Class II.--Breakfast foods made from wheat products. Class III.--Breakfast foods made from oat products. Class IV.--Breakfast foods made from starch and tapioca. Class V.--Breakfast foods made from noodles, spaghetti, and macaroni. Class VI.--Breakfast foods made from barley. Class VII.--Breakfast foods of miscellaneous origin, that is consisting of those compounds of raw material not specified.

[28] U. S. Dept. Agr., Bureau of Chemistry, Bull. 13, Part IX, p. 1345.

=Remarks on Table of Analyses.=--

Class I, Indian Corn Products.--The analytical data show that in the breakfast foods made from Indian corn products the germ has been quite uniformly removed. The quantity of fiber also shows that the maize flour produced has been very carefully bolted. The ash is almost normal, showing only a small addition, probably of salt. The mean quantity of protein is that which would be predicted of an Indian corn product ground by the most approved milling process in order to make as white a flour as possible. These methods of preparing the flour, although so common, are not to be preferred either by reason of palatability or nutritive properties of the products. The old-fashioned milling process makes a more palatable and more nutritious diet and affords a higher degree of heat and energy.

The analysis of the Indian corn products show that they are very much lower in protein than would be expected from an analysis of the whole kernels. The low content of fat in the products is doubtless due to the complete degermination of the grain during the milling and to the further fact that the baking and other preparation of the material tend to occlude the fat particles, making their extraction quite difficult.

Class II, Wheat Products.--The study of wheat products used as breakfast foods shows that the wheat germ is not removed to any very great extent during the preparation of the raw material. In fact the quantity of ether extract appears somewhat greater than would be expected in pure wheat products, and this leads to the supposition that oatmeal or Indian corn must be mixed with the food product in small quantities, since the ether extract in the case of wheat products is more than three times as great as in the case of Indian corn products of a similar character. This is an indication either of the use of mechanical methods as stated above or else to the admixture of other bodies without mention. There does not appear to have been any notable quantity of mineral substance, common salt or otherwise, added during the process of preparation. The quantity of protein in the product is that which would be predicted from the composition of wheat flour from which the samples are supposed to be made.

Class III, Oat Products.--The oat products have evidently been made without any extensive degermination, as is shown by the high content of fat or oil. The average composition of oat products shows that genuine oatmeal is used in their preparation and the probability is that little adulteration is practiced. The high content of oil and protein produces a corresponding depression in the quantity of carbohydrates. The high nutritive value of the product, both in respect of fat and of proteins, is fully illustrated by the analytical data obtained. The calories, as will be noticed, are very much higher than in the corresponding product from Indian corn, wheat, or in fact of any other of the breakfast foods.

Class IV, Products made of starch and tapioca show, in the analytical data, that very high-grade starch materials are employed in the preparation of these bodies. The protein, ether extract, fiber, and ash almost disappear. As shown in the data for the dry substance, more than 99 percent of the whole material consists of carbohydrates, chiefly starch. The calories are correspondingly diminished since starch and sugar have the least heat value of any class of food products, except those of a mineral character. Foods of this kind are highly unbalanced, that is, contain a large excess of starch and sugar, and are often very prejudicial to the health of persons whose ability to digest starch and sugar has been lessened by disease.

Class V, Noodles, spaghetti, and macaroni are often used as breakfast foods, though not by any means so universally as many others in this category. The analytical data show that these bodies correspond very well to the material, that is to the flour, rich in gluten, from which they are supposed to be made. The protein content is high,--the ether extract, fiber, and ash low, and the calories correspond to the chemical composition of the material.

Class VI, Barley Products.--Barley products are not very commonly used as breakfast foods, but the malt used in the preparation of other breakfast foods is usually made of barley, since the barley malt has the highest diastatic value of any of the cereals.

Class VII, Miscellaneous breakfast foods are so called because the character of the materials of which they are made is not known or no statement is made by the manufacturer or dealer concerning them. The analytical data, of course, do not lead to any decision regarding the nature of the raw material employed. The percentage of protein, however, taken in conjunction with the rather low ether extract, indicates that they are probably made chiefly from wheat products.

Much may be said in favor of the use of prepared breakfast foods, for, in so far as I know, they are usually palatable, wholesome, and nutritious. There are many points which may be urged against their general use, chief of which is in regard to their cost. There is no cereal now in general use for edible purposes which is worth as much as two cents per pound in the markets of this country, yet breakfast foods, which are only prepared cereals, are often sold for 10 or 15 cents per pound. This is a high price in comparison with the cost of the raw material, but it must not be forgotten that the cost of manufacture is to be considered. In the second place the cereal foods are undoubtedly best at the moment they are prepared. Unless carefully packed, they may become infected with insects of various kinds, which certainly add nothing to their value and detract very much from their desirability. In moist climates they become infested with mould and even with bacterial growths. Inasmuch as necessarily a large proportion of the prepared cereals remain for an indefinite time unsold, the consumer is liable at any time to come into possession of one of these deteriorated packages. In the third place there is no reason to believe that a prepared breakfast food is any more digestible, nutritious, or favorable to the health of the healthy individual than the broken cereal itself properly cooked. Further than this it may be stated that there is no preparation of cereals better than those which are freshly made from the freshly broken or ground grain. If, therefore, one has the time to properly prepare the fresh grains of the cereals they will be more palatable and more nutritious and equally as digestible as any of the prepared articles. On the other hand, there are cases of diseased or disordered digestion in which the prepared cereals will be more digestible, but this is certainly not the case in a state of health. There is reason to believe, therefore, that the demand for prepared cereals will continue, but the old-fashioned method of preparation of the cereal from the grain will still have its advocates.

I think it may be said with certainty that the proper home preparation of a cereal as a breakfast food will not cost any more than the original cereal itself, and hence the price of this food ought not to be much more than 4 cents per pound without counting the added water in its preparation.

I believe, therefore, that our people of limited means can be safely advised on the score of economy, palatability, and nutrition to prepare their own cereals for ordinary breakfast purposes.

PART VI.

VEGETABLES, CONDIMENTS, FRUITS.

SUCCULENT VEGETABLES.

The term vegetable as applied to food in the broadest sense of the word means that class which distinguishes it from animal food. In a narrower sense, however, the term vegetable is used to denote a certain class of food which is of a succulent or juicy nature. While cereals and fruits are vegetables in the broadest sense of the word they are not in the narrow and common meaning. The

term “vegetable” in this section therefore refers to those substances commonly known as vegetables upon the market and which are characterized by their high water content. On account of this abundance of liquid or juice the term succulent is applied to them. The common vegetables which are included in this class consist of lettuce, spinach, potatoes, cauliflower, beets, radishes, turnips, cabbage, green Indian corn, peas, beans, tomatoes, yams, etc. These vegetables contain in a fresh state from 70 to 95 percent of water. Many of them can be kept for a length of time without deterioration, especially the potato and beet, and for a short time cabbage, radishes, etc., if kept cool and moist. Other kinds of vegetables are not easily preserved for any length of lime except in cold storage, such as lettuce, peas, beans, tomatoes, etc. If the potato and other starchy tubers are kept out of account these vegetables do not have a very high nutritive value, as will be seen by the analysis which follows. They have, however, an important part in the ration because of their palatability and the effect which they have upon the general activity of the alimentary canal. For instance, there is very little nourishment obtained in eating a turnip which perhaps is 95 percent water,--yet its palatability, its condimental character, and its general salutary effect upon digestion is such as to make it worth while to pay even a high price in proportion to its nutriment. For this reason, as well as for their nutritive value, the use of succulent vegetables is to be very highly commended.

In general, as has been said, these vegetables are eaten in a fresh state or after being kept for a considerable time in cold storage or otherwise. The potato, for instance, can be kept by properly covering it in the earth or in bins through the winter. Cabbages are also kept in the same way and many other vegetables without apparent deterioration. These vegetables are often desiccated, and in this way can be kept for a much longer period. Unfortunately no method of desiccation has been developed which preserves entirely the palatability of the vegetable, although its nutrient properties, which are perhaps the least important of its properties in many respects, are preserved to a certain extent by desiccation.

We may, however, leave out of consideration the desiccation of fresh vegetables. Certain of the vegetables above mentioned naturally become desiccated on maturity as in the case of peas and beans, but then they are removed from the category of succulent vegetables. Green Indian corn is also often dried, but in this process its palatability is to a certain extent impaired even when it is prepared for cooking in such a way as to restore practically all of the water whi

THE ABERGELDIE WINTER BOOK.

OPERA HOOD.

IN CROCHET, ORNAMENTED WITH TATTING.

See the Frontispiece.

Materials—16 skeins of Pink and the same of White single Berlin Wool; 3 skeins of White Floss Silk. Walker's Tricot Needle No. 5 Bell gauge.

The Tatting—A large Shuttle, and for the pearl loops a short mesh, which measures 1¾ inches in circumference, and another 1¼ round, are required.

THE CROWN.

Commence with the White wool and the Tricot needle; make a chain of 15 stitches. The whole of the stitches should be worked very loosely.

1st row—Miss the last 4 chain stitches, and work a plain crochet stitch into the next stitch of the foundation chain; then (make 2 chain, miss a stitch of the foundation and work 1 plain crochet stitch, 5 times); turn back.

2nd row—Make 2 chain, miss 2, and work 1 plain stitch in the 2 chain of the last row; repeat to the end, then to Increase work 2 chain and 1 plain again in the last loop; turn back.

Work 7 rows more, the same as the last, when it will be increased to 14 loops. It should measure seven inches across without stretching.

Work 9 rows of the same stitch, but omitting the increased loops at the end of the rows.

19th row—To decrease, miss the last stitch and work 1 plain in the last loop of chain; then 2 chain and 1 plain as before, to the end.

Work 8 rows more as the last. Then work a row of 1 chain and 1 plain in each loop.

Join on the Colored wool, and work a row of plain crochet all round, working two stitches to the side of each of the white rows.

For the second round—Work 4 chain, miss 1 and 1 plain. Repeat and fasten off.

Use the Floss Silk and an Embroidery Needle. Work an ordinary Cross stitch over each of the plain stitches of the Crown, putting the needle into the open spaces.

THE TATTING FLOWERS.

1st CIRCLE—Wind the colored and White Wool together, and fill the Shuttle with it, using the doubled wool as one thread.

Commence a loop, work a double stitch; then using the largest mesh for the pearl loops, work (1 pearl and 1 double alternately 16 times); draw close; leaving a small circle in the centre about the size of the 2nd mesh, and knotting the ends firmly together, cut them off.

2nd CIRCLE—Use the colored wool doubled, and the second sized mesh. Commence a loop, work 1 double, then (1 pearl and 1 double 12 times); draw close and fasten off.

3rd CIRCLE—Use the White Floss, and for the pearl loops the Tricot needle can be used. Commence a loop; work 1 double, (1 pearl and 2 double 8 times); draw close. Fasten off.

Place the second circle over the first, and the silk one in the centre, sewing them together with the silk, then attach them to the crown about an inch from the edge of it.

Make nine Flowers for the Crown and four for the Lappets.

THE LAPPETS.

Work with the White wool and Tricot needle. Make a chain of 11 stitches.

1st row—Raise 11 loops in the ordinary Tricot stitch, and work back, see page 28.

2nd row—Raise a loop, Increase a loop, raise 2 loops; then to _decrease_, put the needle into the three next stitches, and bring the wool through them all. Raise the 2 next loops as before. Increase again, and raise the 2 last loops. There will be 11 loops on the needle. Work back as before. Work 8 rows more as the last.

11th row—Raise the 1st stitch and increase a loop as before; then decrease the two next stitches, taking them together as one stitch; take the next three loops together; then take the two next loops together as one stitch, then Increase a loop as before, and raise the two last loops. There will now be 9 loops. Work back.

12th row—Raise a loop and increase as before; raise the next loop, then take 3 together, raise a loop, increase, raise 2 loops. Work back. Work 8 rows more as the last.

21st row—Raise a loop and increase as before; then put the needle into the next 5 loops, and bring the wool through them all as one stitch; increase again and raise 2 loops: there will now be 7 loops. Work back.

22nd row—Raise a loop and increase; then take the next 3 loops together; increase and raise 2 loops. Work back. Work 20 rows more as the last, or any length preferred.

THE EDGE—With the colored wool, work loosely a row of plain crochet all round the lappet, putting the needle into the spaces formed by the increased stitches. 2 chain and an extra plain stitch should be made at the two ends and centre of the first white row.

Make sufficient of the Scallop Trimming, page 11, to go round the Lappet, using the colored wool doubled, and the smaller mesh for the pearl loops. For the crochet row the wool is to be single.

THE JOINING—work with the Floss Silk, which had better be used double. Commence at the colored row, round the Lappet, and work a plain crochet stitch; then take out the needle and put it into the last stitch of the Scallop Trimming, taking both edges of the plain row, bring the Floss through; then work another plain stitch on the lappet, taking both edges, continue joining and working a plain stitch alternately.

Work a row of Cross stitches with the Floss silk up the centre.

Make the other Lappet the same, sew them to the crown and attach two flowers at each side.

MAZARIN CAPE.

Materials—For the Cape, 4 ounces of single or double Wool, and for the Trimmings 3 skeins of double Berlin Wool of a color which contrasts; Walker’s Tricot Needle No. 7 Bell gauge, a large Tatting Shuttle, and a round Mesh No. 1 Bell gauge.

This Cape is worked in open Crochet ornamented with Tatting, see the Frontispiece.

It will be greatly improved if Floss Silk is introduced as described in the Opera Hood. The centre should then be white with colored Trimming, but any two colors that contrast will look well, as Pearl Grey with Crimson, Mauve with Amber, or Violet with Grey.

THE DIVISIONS.

Commence with the Wool for the centre, and make 15 chain stitches.

1st row—Miss the last 4 chain and work a plain crochet stitch in the next stitch; (then 2 chain, miss 1 and 1 plain, 5 times); turn back. It should measure 3 inches in length without stretching. If single Wool is used it should be worked loosely.

2nd row—Work 3 chain, miss 1 and 1 treble in the last 2 chain; then 2 chain, miss 2 and 1 plain in each loop of 2 chain to the end; turn back.

3rd row—Work the same as the 2nd row.

4th row—3 chain, miss 1, 1 treble in the last loop of chain; then 2 chain, miss 2, and 1 plain as before to the end; and to Increase a loop work 3 chain and 1 plain in the same loop as the last plain stitch; turn back.

5th row—Work the same as the 4th row.

Repeat the last 4 rows 6 times more. As the work will increase two loops every four rows there will now be 20 loops. It is intended that the work should be longer at the sides than in the centre of the division.

30th row—3 chain, miss 1 and 1 treble; then 2 chain, miss 2 and 1 plain as before, for 7 loops, then work 5 loops, making only 1 chain instead of 2 chain; then work 7 loops with 2 chain, and increase in the last loop.

31st row—3 chain, miss 1, 1 treble, then work 7 loops with 2 chain; 6 loops with 1 chain, and 7 loops of 2 chain; then increase at the end.

32nd row—Work 1 chain, miss 1 and 1 plain in each loop of chain to the end; then 1 chain and 1 plain in the last loop. Work 2 rows more as the last, and fasten off.

Work five Divisions more the same, and sew the slanting sides of them together. Three rounds of 1 chain, miss 1 and 1 plain, should be worked along the neck, then commencing at the right point work a plain row up the front, across the neck, and down the other side.

THE TRIMMING IN TATTING.

THE ROSETTE—Fill the Shuttle with the Wool and using the mesh for the pearl loops, commence a loop, work 1 double, (then make a pearl and work a double stitch alternately for 7 loops); draw close. Keep the Wool at the back and join it to the centre pearl.

Work another Rosette the same, and join it to the same pearl of the previous Rosette as before; then keep the Wool as the back and join to the centre pearl of the last Rosette. Repeat the last Rosette until sufficient is made for the sides and border, to which it is to be attached by sewing it with the same colored Wool.

The Rosettes down the Divisions are made in the same manner, but as they are to be smaller, only 5 pearls instead of 7 pearls are to be made for each Rosette.

THE BALLS—Take a yard of the Wool the same color as the Tatting, split it three times, and wind it round the tops of the first and second fingers, take it off the fingers and wind a piece of fine thread about three times very tightly round the middle of the wool, knotting the ends together, also tie in a piece of the wool not split, to form the thread to attach the Balls to the work; cut the wool at each end, rounding it into the shape.

Make sufficient of these Balls to go all round the Edge, placing them about two inches apart.

RETICULE MUFF.

IN TRICOT ECOSSAIS.—SEE FRONTISPIECE.

Materials—4 skeins of Scarlet and 2 of Black double Berlin Wool, or 4-ply Fleecy, Walker’s Tricot Needle No. 6 Bell gauge.

Commence the Outside with the Black wool, and make a chain of 34 stitches. See Instructions for this stitch page 28.

1st row—Miss the last chain stitch. * Put the needle into the next chain stitch, and bring the wool through it in a loop. Repeat from * until there are 34 loops on the needle. Then join on the scarlet wool, and “Work Back.” Join on the black wool.

2nd row—Work with the Black wool, and raise all the loops of the last row; then join on the scarlet wool and Work back.

Repeat as the last row until 16 inches are worked; then, to shape the Flap or part which falls over the pocket, work the same stitch, but decreasing at the beginning and end of every row by taking two stitches together until it is reduced to a point.

THE LINING.

Work with the Scarlet wool and make a piece the same as the outside; when finished it is to be made round by joining the foundation row to the one before the flap is begun, so as to leave it on the outside.

For the Pocket take a piece of merino or silk the length of the muff, and about 8 inches deep double it, and sew the double part to the Lining 4 inches below the joining; then sew one edge of the silk to the joining. Wadding is to be placed between the lining and the outside, which is now to be sewn at the sides and round the flap, but the foundation row is to be joined to the other edge of the

pocket. Finish with a Fur Trimming or Border, as given in the Winter Book, 1862, round the end and flap, which must be secured with a loop and button.

CROSSOVER SHAWL.

IN TRICOT ECOSSAIS, WITH TATTING BORDER.

See the Frontispiece.

Materials—For the Tricot, 6 ounces of Mauve, Blue, or Magenta 4-ply Fleecy, Walker's Tricot Needle No. 3 Bell gauge. Berlin Wool 8-ply can be used, or 3-ply Fleecy.

For the Border, a skein of Black and two of White double Berlin Wool, a large Shuttle, and a Mesh No. 1 Bell gauge.

THE BACK.

Commence with the Colored Fleecy, and the Tricot Needle. Make a chain of 7 stitches.

1st row—Miss the last chain stitch. * Put the needle into the next stitch, and bring the wool through in a loop. Repeat from * until there are 7 loops on the needle. Work back. See Instructions, page 28, at the end of the book.

2nd row—Raise the 7 loops of the 1st row, and work back.

3rd row—Raise a loop, then Increase a loop by putting the needle between the upright stitches; Raise 3 loops as usual; then Increase another loop; raise the 2 last loops. Work back.

4th row—Raise a loop, Increase, raise 5 loops, increase again, raise 2 loops. Work back.

5th Row—Raise a loop, increase, raise 7 loops, increase again, raise 2 loops. Work back.

6th row—Raise a loop, increase, then raise all the loops to within two of the end; increase again, and raise the two last loops. Work back. The work should be loose. As a guide for the size of the stitch, the last row should measure 4 inches across, and these 6 rows 2½ inches in depth.

Work 5 rows more the same as the 6th row.

12th row—Raise all the loops without increasing, and work back.

Work 4 rows as the 6th row, that is increasing 2 stitches each row, and then work every 5th row without increasing until 37 rows in all are worked, when there will be 65 stitches.

Work 4 rows without shaping. If for an extra size a few more rows may be added here, and also at the plain rows on each shoulder. This finishes the back.

TO SHAPE THE RIGHT FRONT—1st row—Raise all the loops of the last row until there are 28 on the needle. Work back.

2nd and 3rd rows—Raise all the loops to the two last, then decrease by taking these loops together as one stitch. Work back.

4th row—Raise a loop, then decrease as before, raise the rest to the end. Work back.

Then work 4 rows plain without shaping.

Repeat as the 4th row, and the 4 rows plain after it, 5 times more; that is decreasing a stitch at the beginning of every 5th row; the left selvedge should be quite straight.

Then to shape the end, decrease a stitch at the beginning and end of every 3rd row, until it is reduced to a point.

TO SHAPE THE LEFT FRONT—1st row—Commence at the stitches left at the back, and leaving 9 for the neck, raise the remaining 28 loops as usual. Work back.

2nd and 3rd rows—Work 2 rows, decreasing a loop at the beginning of each row. All the rows must now be kept straight at the beginning.

Work 4 rows plain, and at the end of every 5th row decrease a stitch, in all 6 times. Then decrease a stitch at the beginning and end of every 3rd row until it is reduced to a point.

THE TATTING BORDER.

THE DOT—Fill the Shuttle with the White Wool, and use the Tricot Needle for the pearl loops. Commence a loop, work 3 double stitches, then (1 pearl loop and 3 double stitches twice); draw quite close and reverse the work.

Commence the next Dot close to the last and repeat the dot, reversing them after each is made. Work sufficient to go all round the Tricot.

THE EDGE—Work with the Black Wool, and commencing at the last pearl of the Dots, crochet a plain stitch in it; then work another plain stitch in the next pearl of the same Dot, and missing the Dot which turns down, work a plain stitch in the 1st pearl of the next dot but one. Repeat working a plain stitch in the two pearls of every other dot.

THE JOINING—Work with the Black wool, and commencing at the left corner of the Tricot, work a plain crochet stitch between the rows of it; then, to join the Tatting, take out the needle, put it into a pearl of a Dot, and bringing the loop through work a plain stitch on the Tricot, and continue the same until the Tatting is joined. To round the corners so that the Border may lie flat, the needle should be put into the last pearl of one dot and the 1st pearl of the next, and worked as one stitch. This should be done five or six times. With the same colored wool as the Tricot, make sufficient of the Scalloped Trimming to go all round, and join it to the black row of the Border with the black wool, always putting the needle into both edges of the plain rows.

TATTING SCALLOP TRIMMING.

Materials—The edging being used to ornament more than one of the patterns in this book, the materials are given with each article.

THE SCALLOPS—Fill the Shuttle with the Wool, and commencing a loop work 2 double stitches, then with the Mesh or pin (make a pearl loop and work a double stitch alternately, until 6 loops are made); then work another double stitch and draw the loop nearly close, leaving a space in the centre the size of the Mesh.

Leave three-quarters of an inch of Wool before commencing the next Scallop. Continue them until the length is made.

Work with the Tricot Needle; take the Tatting and, keeping the straight edge at the top, work a plain Crochet stitch in the last pearl of the Scallop; then work 2 plain in the space in the centre of the Scallop and 1 plain in the last pearl. The thread which connects the Scallops is to be worked under these stitches. Continue working 4 plain stitches to each Scallop.

GENTLEMAN'S SOCK OR HALF-HOSE.

RIBBED KNITTING.

Materials—4 ounces of plain or speckled Fingering Yarn, and 1 ounce of a contrasting color for the top and toe. 5 Knitting Needles No. 17 Bell gauge.

The following directions will make a full-sized Stocking, viz—12 inches round the top of the leg, 12 inches in length from the top to the heel, and 11 inches long in the foot. By using Needles Nos. 16 or 18 it will make a size larger or smaller.

THE LEG—Use the color for the top—Cast on 24 stitches on each of four needles, keeping the fifth to make it round.

1st round—Pearl 3 stitches and knit 3 stitches alternately all round; in all 96 stitches.

Work 30 rounds or two inches more the same, always knitting or pearling the same stitches throughout the leg.—With the other color, knit 8 inches more the same.

TO SHAPE THE HEEL—Knit 23 stitches plain off the 1st needle which leaves a stitch, and putting it on the 2nd needle turn back, so as to work on the 23 stitches. Slip the 1st stitch and pearl the 22 stitches, then, using the same needle, pearl 20 stitches off the next needle, which leaves 4 stitches; put them on the next needle and turn back. The 53 stitches on the other needles are left for

the Instep.

1st row—Slip the 1st stitch, knit 20, pearl 1, knit 21; turn back.

2nd row—Slip 1, pearl 42 stitches; turn back.

Repeat the 2 last rows 22 times more.

TO ROUND THE HEEL. 47th row—Slip 1, knit 15, knit 2 together, knit 6, knit 2 together, knit 1, turn back, leaving 16 stitches on the other needle.

* * * * *

[Illustration:

MUFFATEE. GENTLEMAN'S SOCK. BABY'S BOOT.

LADY'S STOCKING. SLEEPING SOCK.]

* * * * *

48th row—Slip 1, pearl 10, turn back, leaving 14 stitches—slip 1, knit 2 together, knit 7, knit 2 together, knit 1, turn back; † slip 1, pearl 12, that is, 2 stitches on those left unworked, turn back—slip 1, knit 2 together, knit 9, knit 2 together, knit 1, turn back. Repeat from † 6 times more, always knitting or pearling 2 stitches more each time, so as every row to use two of the stitches left unworked; when finished, there will be 25 stitches on the needle.

THE INSTEP—Commence at the end of the 53 stitches left unworked, and with another needle raise 23 stitches from the selvedge formed by the rows at the right side of the heel.

Take another needle, and knit the 25 stitches left from the heel.

Then with the 5th needle, raise 23 stitches down the selvedge of the left side of the heel, and with the same needle knit off the first plain stitch of the 53. Put 51 of these instep stitches on one needle, and place the remaining stitch on the next needle to the left. It will now be 124 stitches round.

1st round—Work across the instep. (Pearl 3 and knit 3, alternately as before, 8 times) then pearl 3; knit 1, knit 2 together, knit 67 _plain_; then knit 2 together, knit 1 plain.

2nd round—(Pearl 3 and knit 3, 8 times), pearl 3, knit the rest of the round all plain.

Repeat these two rounds 16 times more, knitting 2 stitches less at the stitches marked in italics each time.

Then knit 50 rounds the same as the 2nd round; when finished knit 20 rounds all plain.

THE TOE—Join on the other color and decrease thus—

1st round—Knit 2 together, knit 37 plain, knit 2 together, knit 4 plain. Repeat once more to finish the round.

2nd round—All plain.

Repeat the 2 last rounds 16 times more, knitting 2 plain less each time instead of 37.

Place the remaining stitches together so as to double the work, and knitting a stitch off each needle together, cast off the remaining stitches.

A SLEEPING SOCK.

KNITTING.—SEE PAGE 13.

Materials—For a Lady, 2 skeins of white 3-ply Fleecy, and a pair of knitting pins, No. 12 Bell gauge; for a Gentleman the pins must be No. 10.

Commence at the sole. Cast on 28 stitches.

1st row—Slip 1, then increase a stitch by knitting the next stitch, but before taking it off the left pin, put the needle into the back of the same stitch and knit it off the pin; knit the rest of the row plain. Work 9 rows more the same.

Then work 18 rows, increasing in the same way at the beginning of every alternate row only, which will make one side slant more than the other; there will now be 47 stitches.

Knit 6 rows plain, always slipping the 1st stitch.

TO FORM THE INSTEP—Slip 1, knit 29, turn back, leaving 17 stitches on the pin: and on the 30 stitches knit 26 rows plain. The wool will be at the side nearest the stitches left, and with it cast 17 stitches on the pin with the 30 stitches, in all 47 stitches; and for the other side of the sole, knit 6 rows plain.

Next row—Slip 1, knit 2 together, knit the rest plain. Then knit a row plain. Work the last two rows 8 times more. Then 10 rows, decreasing every row, and cast off.

THE LEG—Return to the stitches left, and with the same pin raise 14 stitches from the selvedge formed by the rows across the instep, thus: put the pin into the nearest stitch at the edge, and bring the wool through in a loop on it; then in the same manner raise 17 stitches from the stitches cast on; there will now be 48 stitches.

1st row—Slip 1, knit 1, then (pearl 2 and knit 2 alternately to the end).

Knit 29 rows more the same, then 6 rows plain, and cast off.

Sew the sides together, then the 1st and last rows of the sole, and the slanting sides, drawing the straight rows at the toe together.

BABY'S CROCHET BOOT.

Materials—8 skeins of white and 16 of colored Single Berlin Wool; Walker's Penelope Crochet Needle, No. 1. See page 13.

Commence at the Toe, and with the colored wool make 16 chain. The work should be tight.

1st row—Miss 1, 7 plain, 3 plain in one stitch, 7 plain, then 1 chain to form the selvedge, turn back. Now work in raised crochet, that is, putting the needle into the lower edge of the stitch of the previous row, and working a plain stitch, which will leave the upper edge in the front.

2nd row—Miss the 1 chain, work 8 plain always raised, then 3 stitches in one, 8 plain as before, 1 chain, turn back.

3rd row—Miss the 1 chain, then the rest plain; 1 chain at the end.

Repeat the last 2 rows, 9 times more, working a stitch more before and after the centre stitches each repeat. Then, to form the side of the boot,

22nd row—Miss the 1 chain, then 18 plain, still raised, 1 chain, turn back.

Work 37 rows more as the last, and when finished, crochet the last row to the other half of the front.
